CONIC SECTIONS.
CONIC SECTIONS are those parts of a cone which are cut off by a plane. They are of three kinds, viz. the circle, the ellipse, and the hyperbola. The circle is formed by a plane cutting the cone parallel to its base. The ellipse is formed by a plane cutting the cone at an angle less than that of the cone's side. The hyperbola is formed by a plane cutting the cone at an angle greater than that of the cone's side.

PLASTICS TO RAZIN

PLASTICS, in the modern meaning of the word, are synthetic materials that are capable of being formed into usable products by heating, milling, molding, and similar processes. The term is derived from the Greek *plastikos*, "to form." By some interpretations of the word, rubber and other natural products are said to be plastic, but the modern definition, especially in relation to industry, excludes rubber and also such other natural products as wood, leather, and metals. In simplest terms, plastics can be described as resins in their molded form (although not all plastics are resins and not all resins can be or necessarily are molded; they can be cast or converted to coatings, self-supporting films, or fibres). Plastics are one of the physical manifestations of resins, as indicated in the title of one of the first books in this field, *Synthetic Resins and Their Plastics*, by Carleton Ellis (1923). (See RESINS.)

The term plastic is, therefore, essentially a commercial classification to which no strictly scientific definition can be applied. The Society of the Plastics Industry has defined plastics as "any one of a large and varied group of materials consisting wholly or in part of combinations of carbon with oxygen, hydrogen, nitrogen, and other organic or inorganic elements which, while solid in the finished state, at some stage in its manufacture is made liquid, and thus capable of being formed into various shapes, most usually through the application, either singly or together, of heat and pressure."

The use of plastics began slowly in the last half of the 19th century following the introduction of Celluloid and other cellulose plastics. The invention of Bakelite brought about a marked increase in the use of plastics early in the 20th century. Shortages of natural materials caused by World Wars I and II led to the development of new plastic substitutes. By the 1960s plastics were available in forms that were superior, in certain uses, at least, to leather, paper, glass, metal, wood, rubber, and other natural materials. Plastics were used for a wide variety of purposes; for example, in the manufacture of automobile parts and bodies, toys, television cabinets, clothing, housewares, wall and floor coverings, beverage cases, military body armour, cigarette packages, and furniture.

The leading plastics, on the basis of tonnages produced in the 1960s, were the polyolefin resins, vinyl resins, styrene-type plas-

tics, phenolic and other coal tar acid resins, alkyds, urea and melamine resins, coumarone-indene and petroleum polymer resins, polyester resins, cellulose plastics, polyamide resins, epoxy resins, and polyurethanes.

By custom, the fibre industry is considered to be outside the plastics industry, although the same raw materials—polyamides (nylon), cellulose, and cellulose acetate—are used by the two industries. The manufacture of films, such as photographic film and cellophane, is not considered part of the plastics industry. Even though polymers may be converted to leatherlike products, it is current policy to refer to these as synthetic pomeric materials and not as plastics.

The major headings of this article are as follows:

I. History of Development and Fabrication

1. Early Observations of Resinification
2. Causes of Resinification
3. Production of New Plastics
4. Fabrication Technology

II. Plastic Materials

A. Cellulose Plastics

1. Nitrocellulose
2. Cellulose Acetate
3. Cellulose Acetobutyrate and Other Esters
4. Cellulose Ethers

B. Other Natural Products

1. Casein Plastics
2. Shellac

C. Synthetic Resin Plastics

1. Thermosetting Resins
2. Thermoplastic Resins
3. Foamed Plastics

I. HISTORY OF DEVELOPMENT AND FABRICATION

The modern plastics industry represents an integration of many different and unrelated bodies of knowledge. One part is derived from investigations into the chemistry, physics, and biology of such high-molecular-weight natural products as natural resins, rubber, gutta-percha, cotton, cellulose, ramie, pectins, chitin, starch, glycogen, wool, silk, and hair. Initially, optical methods were used in the investigation of these products; later ultramicroscopy was employed. Somewhat later colloidal chemical methods were developed and used in the study of the gross morphology of these substances. X-rays indicated that some natural products, such as

cellulose, gutta-percha, and silk, were crystalline; others were amorphous; and still others were both crystalline and amorphous, depending on the state. Natural rubber in the unstretched state was amorphous when examined by X-ray diffraction methods, but it became crystalline when stretched. The ultracentrifuge made it possible to measure viscosity and sedimentation of these products under extremely high centrifugal forces. The idea grew that the natural products must of necessity be of a very high molecular weight.

1. Early Observations of Resinification.—Early chemists observed that in the preparation and synthesis of new compounds, materials would often resinify, through unknown and uncontrollable reactions, either during the course of the preparation or spontaneously after the product was formed and isolated. J. J. Berzelius in 1833 introduced the term "polymer," which eventually came to mean a giant molecule with the same percentage composition as some smaller starting substance (called the monomer). The term high polymer is now restricted to high-molecular-weight compounds composed of simple molecules, while the term polymerization (*q.v.*) relates to the process by which large molecules are synthesized from smaller ones.

In the same year (1833), nitrocellulose was prepared; H. V. Regnault in 1838 noted that vinyl chloride polymerized in sunlight, and in the following year E. Simon polymerized styrene; J. Redtenbacher prepared acrylic acid in 1843; W. Caspary and B. Tollens in 1873 synthesized the methyl, ethyl, and allyl esters; and G. W. A. Kahlbaum prepared the polymer of methyl acrylate in 1880. Isoprene was prepared by G. Williams in 1860, and it was polymerized by G. Bouchardat in 1879. R. Anshutz prepared polymers of itaconic acid esters in 1881, and in 1865 E. Frankland and B. F. Duppa discovered a method of making ethyl methacrylate from hydroxyisobutyric esters. Many condensation-type resins were also discovered during this interval, and many polyesters were also prepared, particularly those derived from glycerol and dibasic acids. The transformation of ethylene oxide from monomer to polymer was studied by M. A. von Lourenço, who showed that the boiling point and the viscosity increased progressively with the molecular weight of the polymer. I. Ostromislen-sky maintained that there was a stepwise synthesis of rubberlike substances. Similarly, it was observed that when glycine was condensed, a series of products was obtained in which there was a regular change in the physical properties. Emil Fischer performed his classical work in synthesizing numerous polypeptides out of simple amino acids, and although he showed that his synthetic product possessed many of the properties of the hydrolytic products of naturally occurring proteins, it was generally considered that the natural products (such as proteins, cellulose, and rubber) possessed unique properties that were not shared by laboratory products.

Part of the dilemma presented by the different behaviour of natural and synthetic products was resolved by Hermann Staudinger (*q.v.*) in 1926. He demonstrated the interrelationship between the structure as determined physically by X-rays and the size and structure of the polymer as determined chemically from analysis, as well as the size of the molecule determined by the nature and number of end groups existing in the high-molecular-weight compound. These various ideas were consolidated in Staudinger's *Die hochmolekularen organischen Verbindungen-Kautschuk und Cellulose* (1932), in which he shows the similarities between polystyrene, a synthetic substance, and rubber, and between the polyoxymethylenes and naturally occurring cellulose. He demonstrated that the products of the laboratory have many properties in common with natural products and that the synthetic materials can be used as prototypes in evaluating the natural materials.

2. Causes of Resinification.—The causes of resinification of organic compounds remained obscure for a long time, since the chemical reactions that led to it were unknown. It was recognized very early that unsaturated compounds yielded resins, and when the phenol-formaldehyde resins were first introduced the unsaturation hypothesis was advanced. The resin formation of phenol-formaldehyde resins was attributed to the polymerization

of methylene quinones. Somewhat later the concept of "resinophoric" groupings was introduced by W. Herzog and I. Kreidl, and although the theory was shown to be untenable, it focused attention on the relationship of structure and it led to studies that revealed there were essentially two chemical reactions responsible for resinification: one involving a condensation reaction, where the polymer differs from the starting material by the elements eliminated in the condensation; and a second involving a polymerization reaction, where the polymer and starting material have the same chemical composition.

About the same time that Staudinger was conducting his investigations in Europe, studies were being made in the United States on various condensation-type resins, and the foundation was laid for the so-called functionality concepts that enabled a clear distinction to be made between the chemistry of the thermoplastic resins and the behaviour of the thermosetting type of product. W. H. Carothers, using condensation reactions, made fibrelike materials, *e.g.*, nylon, that possessed many of the crystalline properties previously associated only with natural products.

To make a chemical compound condense to a material of high molecular weight, each molecule of that compound must contain two or more functional groups that can react with one another. When a compound contains molecules possessing only one functional group, these molecules on interaction will yield a product that can be, at best, twice as large as the molecules of the starting material. When a compound possesses molecules containing more than two functional groups, then each molecule can be joined to two other molecules. Preferably these functional groups should be at the ends of the molecule or at least so situated sterically that cyclization (ring formation) or intramolecular reaction cannot occur. These important steric, or spatial, configuration factors were first thoroughly evaluated by Carothers. When all these requirements are met, it is possible for the functional groups to react with one another intermolecularly, leading to a reaction product containing long chains. These long chains are molecules of high molecular weight. When the product contains molecules having more than two functional groups, the reaction product formed by condensation leads to the formation of complex structures. Such complex molecules are responsible for the industrially valuable physical properties of plastics.

The functional groups referred to above are simply any chemical groups that can react with others. For example, two organic acid molecules can react to form an anhydride (1, below). If the original starting molecule contains two acid groups, and these groups are so situated sterically that ring formation can occur, then ring formation takes place without the formation of a high-molecular-weight compound; for example, succinic acid dehydrates to an anhydride (2). If, on the other hand, the acid groups are situated sufficiently far apart to preclude cyclization (as in sebacic acid), polymeric, high-molecular-weight, linear anhydrides are formed (3).

Likewise, an alcohol and acid can react to form an ester. If a simple organic molecule contains an acidic group on one end and an alcoholic group on the other, the initial condensation product still possesses a hydroxyl group and a carboxyl group, which can react similarly to the starting materials (4).

Such a condensation can proceed to yield a high-molecular-weight polymer. Unreacted groups at the ends of such large molecules are called "end groups."

A similar situation exists with respect to polymerization products. Under certain conditions, cyclization to a low-molecular-weight compound can occur (5); or if the conditions are properly selected, a polymer of high molecular weight may result (6).

3. Production of New Plastics.—Later studies gave some insight into the size and structure of the large molecules in plastic materials. Minor changes during the preparation, and the addition of small amounts of other chemicals, may markedly change both the proportion and the distribution of the molecular species, leading to formation of a new product of differing physical properties. Moreover, the same materials, under different chemical processing, may yield resins and polymers of widely different physical characteristics. By means of these two procedures innumerable types of resinous compositions can be produced. Since the chemical industry is the source of raw materials for plastic products, it follows that as soon as a new chemical is developed it is immediately tested by plastic manufacturers to determine whether it may serve as a partial or a total replacement for the material then employed. New materials are quickly introduced into the plastics industry, allowing the preparation of new products with different structures and different characteristics.

4. Fabrication Technology.—The development of molding technology parallels the study of resinification, since it was only by fabricating the synthetic laboratory products that these materials could be turned into articles of commerce. The art of molding developed following Charles Goodyear's discovery of the vulcanization of rubber in 1839. This involved the use of a simple hand-operated hydraulic press of a sort that came to be used in all types of molding operations in which the mold must be sufficiently light to warrant manual handling. With the development of phenolic resins, larger objects could be molded, and this necessitated the improvement of compression molding to increase the output of any single mold. Automatic presses were developed and pins were incorporated into the mold itself to permit automatic ejection of molded pieces. Where metallic inserts had to be introduced into the specimen during molding, semiautomatic presses were constructed. To reduce error and to speed production, automatic presses were fashioned that could measure the charge, preheat the charge, load it into the cavity, close the mold, mold the object, open the mold, and eject the final piece. Still greater efficiencies are achieved by electronic preheating of the plastic before introducing it into the mold.

Injection Molding.—Conventional compression molding is both awkward and expensive when applied to thermoplastic materials. Where compression molding is used on thermosetting materials, the mold can be kept at a constant temperature. During the molding and curing operations, the plasticity decreases because of chemical reaction, with the result that the product becomes sufficiently rigid, even while hot, to be ejected from the mold. Thermoplastic resins, on the other hand, do not undergo any chemical change, and the fabricated piece cannot be taken out until the mold has been cooled to a point at which the piece becomes rigid.

The idea arose that if it were possible to inject the hot plastic into a cool mold, following the procedure used in the die-casting of metals, it would obviate the periodic heating and cooling of the mold. The first experiments directed toward injection molding were made by John and Isaiah Hyatt, who were also instrumental in first commercializing nitrocellulose (see below), but they abandoned the work. Later the technique was revived, this time in Germany. The first presses had an injection capacity of about 0.5 to 1.5 oz. per cycle and were useful only for the manufacture of small objects such as buttons, combs, and costume jewelry. Once the value of these presses was demonstrated and a suitable plastic composition developed, larger and larger presses

ADAPTED FROM H. SIMMONS, "A CONCISE GUIDE TO PLASTICS," 1957
FIG. 1.—SCHEMATIC DIAGRAM OF AN INJECTION MOLDING OPERATION WITH THE MOLD CLOSED (ABOVE) AND OPEN (BELOW)

were designed until it became possible to inject 32 oz. of plastic into a mold in a single cycle.

Transfer Molding.—The advent of injection equipment speeded up the production of thermoplastic resins. To increase the mold capacity of the thermosetting resins a type of injection molding known as transfer molding was developed, whereby the molten plastic was transferred from the heated zone into the mold. Since thermosetting resins remain plastic for only a very short time, they cannot be preheated in the manner employed for thermoplastic resins; the heating chamber must be loaded for each cycle and the heated charge forced into a hot mold. Transfer molding not only decreases the time of molding of certain objects but also allows the introduction of inserts, which sometimes cannot be introduced into conventional compression moldings; the plastic enters the mold in a highly fluid state and will not displace or break fragile inserts such as glass and fine metal parts. The separation of resin and filler is minimized by this type of molding, and the resulting molded objects are stronger, of more uniform density, and freer of gas pockets.

ADAPTED FROM H. SIMMONS, "A CONCISE GUIDE TO PLASTICS," 1957
FIG. 2.—SCHEMATIC DIAGRAM OF A TRANSFER MOLDING OPERATION

Extrusion Molding.—A third type of molding is by the so-called extrusion method, which was used for many years in the rubber industry before it was applied to thermoplastic resins. The resin is fed from a hopper, thence to a screw conveyor where it is heated and from which it emerges through a die in a continuous strip in the form of the die opening. To minimize distortion, the heated plastic is frequently supported on a moving belt. By this means rods and tubing of various sizes and shapes can be produced efficiently.

II. PLASTIC MATERIALS

A. CELLULOSE PLASTICS

1. Nitrocellulose.—In 1833 Henri Braconnot, a professor of chemistry at Nancy, prepared a "xyloidine" by treating starch, sawdust, and cotton with nitric acid. He found that this material was soluble in wood vinegar and attempted to make coatings, films, and shaped articles of it. In these early experiments lay the beginnings of both the plastics and the lacquer-coating industries. Somewhat later, in 1846, C. F. Schönbein nitrated cotton by using a mixture of nitric and sulfuric acids. He also found that he

ADAPTED FROM H. SIMONDS, "A CONCISE GUIDE TO PLASTICS," 1937

FIG. 3.—SCHEMATIC DIAGRAM OF AN EXTRUSION MOLDING OPERATION

could dissolve the nitrocellulose (*q.v.*) in a mixture of ether and ethyl alcohol.

Investigations into various methods of conducting nitration indicated that several types of nitrated cotton might be made. The nitrocellulose possessing the highest degree of nitration, in which the nitrogen content was more than 13%, was referred to as guncotton; when the nitrogen content was 12.6 to 12.8%, the material was referred to as pyrocollodion; and when the nitrogen content was 11.5 to 12% the materials were known as pyroxylin, collodion, or photocotton. The nitration reaction is very complicated, involving a heterogeneous system of cellulose, nitric and sulfuric acids, and water. Each constituent may play several physical and chemical roles, the reagents swelling as well as reacting with the cellulose. (See also GUNCOTTON; COLLODION.)

Some attempts had been made to prepare coating compositions out of collodion, but the first successful plastic was made in 1868 by a young U.S. printer, John W. Hyatt, by dissolving nitrocellulose under pressure. In 1863 Phelan and Collander, manufacturers of ivory billiard balls, had offered a \$10,000 reward to anyone who developed an adequate substitute for natural ivory. Procedures for making the balls from a mixture of pyroxylin and camphor were disclosed in patents issued to Hyatt and his brother Isaiah between 1870 and 1872. Subsequently, 75 patents were taken out on various procedures for plasticizing nitrocellulose. In 1870 the Albany Dental Plate Company was organized by Hyatt, and in 1871 the Celluloid Manufacturing Company was formed. The immediate use of this material was for dental plate blanks; later the plastic was used in sheet form for automobile side curtains, as well as for the well-known Celluloid collars. Toughness, flexibility, and good appearance were the properties that made the material suitable for use in a wide variety of items such as combs, brush handles, spectacle frames, and various novelty and decorative items. (See also CELLULOID.)

In 1884 Count Hilaire de Chardonnet, a pupil of Louis Pasteur, deposited with the French Academy of Sciences a document entitled "Artificial Textile Material Resembling Silk." The paper, opened in 1887, described a method of transforming guncotton into fibrous, silklike material. At the Paris Exposition in 1889 Chardonnet was awarded the grand prize for his discovery. The fibre was highly flammable, but it focused attention on the possibility of manufacturing synthetic filaments from a vegetable source.

The discovery by John H. Stevens that amyl acetate could be used as a solvent for nitrocellulose was made in 1882. This solvent proved to be far superior to anything used previously and enabled uniform films to be made without haze. The first successful attempt to secure transparent flexible film for photographic purposes was made by H. Goodwin of Newark, N.J., during the years 1887-98. A somewhat similar process was developed independently by H. Reichenbach in 1889. Further work resulted in processes that allowed the nitrocellulose to be fabricated in continuous fashion, enabling the production of suitable base for both still and motion-picture photography. Another important use for nitrocellulose in sheet form was in safety glass,

in which sheet nitrocellulose was laminated between glass sheets to form a glass-plastic sandwich. The nitrocellulose film discoloured rapidly, however, and was eventually superseded by other, more light-stable plastics; but it served as an invaluable guide and established the importance of safety glass in the automotive industry.

Prior to World War I, Russia supplied the largest volume of fusel oil. This oil, remaining after the distillation of grain alcohol, was the raw material used in the synthesis of amyl acetate. Following the loss of this source of supply during the Russian Revolution and with the loss of additional supplies caused by the enactment of the U.S. prohibition laws, the amount of this potential lacquer solvent became exceedingly small. New solvents for nitrocellulose were being developed rapidly, however. During 1920-23 the normal butyl alcohol process was perfected by Chaim Weizmann, and about the same time anhydrous ethyl acetate made its appearance. Moreover, plasticizers other than camphor were being developed. Tricresyl phosphate was prepared in 1920 and triacetin in 1921.

Since the theoretical nitrogen content for mono-, di-, and trinitrated forms of cellulose is 6.77, 11.3, and 14.16%, respectively, it can readily be seen from the nature of the manufactured products that the most valuable nitrocellulose plastic compositions contain from two to three nitrate groups per glucose residue in the cellulose molecule. Explosives are made from those materials having from 12.2 to 13.8% of nitrogen; lacquers and films from 11.5 to 12.2%; and plastics from 10.5 to 11.5%. The properties of the nitrocellulose thus secured are dependent not only on the degree of nitration but also on the uniformity of nitration of the cellulose molecule. Moreover, the length of the chain of the nitrocellulose molecule is very important since the longer the chain—that is, the larger the value of x in the equation below—the more viscous the solution of nitrocellulose in organic liquids. The reaction leading to cellulose trinitrate may be expressed by

For coating applications high-viscosity lacquers are a disadvantage, since excessively large amounts of solvent would be required to produce the necessary thin films.

Several factors contributed to a twentyfold expansion of the use of nitrocellulose in the decade following World War I: (1) the availability of desirable solvents at relatively low cost; (2) the large quantities of nitrocellulose on hand following termination of the war; (3) the development of a method for preparing lacquers possessing a high-solids content with relatively low viscosity; and (4) the tremendous demand for quick-drying finishes by the rapidly expanding automotive industry. Through the use of nitrocellulose with alkyds, it was possible to decrease the time of finishing an automobile body from weeks to hours.

For plastic manufacture, the pyroxylin is mixed with alcohol and camphor and kneaded into a doughlike mass. Colouring matter is added, either in the form of dyes for transparent colours or as pigments for opaque colours. The coloured masses are rolled to discharge some of the volatile solvent, sheeted, and pressed into blocks. After seasoning, the blocks are sliced; then either they are further fabricated, or the process is repeated for various mottled and variegated effects. The sheets may be molded and when sufficiently soft may be fashioned by "blow molding" into hollow objects. Rods and tubes are fabricated by extrusion.

Despite its obvious disadvantages of flammability, discoloration on aging, and limited resistance to heat and to strong organic solvents such as alcohols, ketones, and esters, the nitrocellulose plastic is colourful, tough, flexible, of good appearance, and resistant to wear, water, and humidity. It is easy to fabricate into many diverse forms and finds wide acceptance for billiard balls, piano keys, mirror and spectacle frames, combs, brush handles, machine keys, radio dials, and novelty and decorative items.

2. Cellulose Acetate.—The deficiency inherent in nitrocellulose for plastic use brought up the possibility of adapting other esters of cellulose, particularly the esters of organic acids. Paul Schützenberger acetylated cellulose in 1865, and A. Franchimont

in 1879 found that the esterification reaction could be catalyzed by sulfuric acid. In 1894 C. F. Cross and E. J. Bevan, working in England, patented a process for preparing a chloroform-soluble type of cellulose acetate. The most important commercial development was made by G. W. Miles in 1903-05 with the discovery that if the highly acetylated cellulose was subjected to hydrolysis, it became transformed to a less highly acetylated compound that was soluble in cheap organic solvents such as acetone. In 1911 Henri Dreyfus perfected a manufacturing process for the preparation of the acetylated compound and its hydrolysis. The same basic process is employed in the manufacture of the cellulose acetate as that employed in the manufacture of a nitrate, except that the anhydride used as the esterification reagent results in acetic acid rather than water as the by-product.

The cellulose acetate, with an acetate content of about 62.5%, is then hydrolyzed, precipitated, washed, and dried. Depending on whether the acetate is to be used as a film, molding powder, or safety glass, different quantities, amounts, and types of plasticizers are employed, allowing one type of polymer to fill many diverse applications.

The first use of this material was in the so-called "safety film" for photographic use. Acetone-soluble cellulose acetate found extensive use in World War I as the dope for coating aircraft wings because it was much less flammable than nitrocellulose. After the war the excess plant capacity was used to produce cellulose acetate as an acetate rayon. However, another very important development, the new procedure for molding thermoplastic resins mentioned above, was occurring simultaneously. It was found that the acetate was particularly amenable to injection molding, and the cellulose-acetate plastic was given a new impetus by this rapid and efficient means of fabrication. The acetate was preferred since the nitrate could not be subjected to the temperature required in injection molding. Cellulose acetate became widely used in the automotive industry because of its mechanical strength, toughness, wear-resistance, transparency, and ease of moldability. Its high resistance to impact made it a desirable material for protective goggles, tool handles, oil gauges, and the like. In fibre form, cellulose acetate became one of the more effective filters for removing phenolic bodies from tobacco smoke.

3. Cellulose Acetobutyrate and Other Esters.—Since one of the more serious limitations of cellulose acetate lies in its poor resistance to moisture and weathering, attempts were made to use longer, less water-soluble organic acids in esterification. The use of mixed acids was not overlooked, and it was found that a mixture of butyric and acetic acids (as anhydrides) yielded mixed esters that were very similar in properties to the acetate but were more resistant to moisture and weathering and had superior adhesion qualities. When molded by injection, cellulose acetobutyrate required somewhat less pressure than acetate and yielded better welded joints.

Other cellulose esters were prepared commercially. During World War II processes for the manufacture of propionic acid and its anhydride were developed, and cellulose esters made from this acid appeared on the market. Since propionic acid contains three carbon atoms, it is intermediate between acetic and butyric acids. It follows that the cellulose propionate possesses many excellent properties similar to those exhibited by the acetobutyrate as well as many characteristics of its own, particularly a shorter molding cycle and easier machining qualities. Cellulose benzoate was manufactured in Germany, but the material did not find a market in the U.S.

4. Cellulose Ethers.—Since cellulose is a polyhydric alcohol, it can undergo etherification reactions as well as the esterification reactions mentioned above. Ether linkages cannot be saponified, so it is not surprising to find that the cellulose ethers are among the more stable of the cellulose derivatives. The idea of ethylating cellulose was first conceived by W. von Suida in 1905 with the primary object of changing the affinity of cellulose for dyestuffs. Cellulose ethers were studied simultaneously by Leon Liliendal

in Austria, Otto Leuchs in Germany, and Henri Dreyfus in France. It was found that the cellulose ethers, and in particular ethyl cellulose, were soluble in organic liquids and possessed potentialities in plastic as well as in lacquer and in rayon applications.

Ethyl cellulose was first produced commercially in Germany and it was not until 1935 that large-scale production was undertaken in the U.S. The chief uses of ethyl cellulose are in coatings, in adhesives, and as plastics possessing a high degree of toughness over a wide temperature range.

Many other cellulose ethers are known. The methyl cellulose, glycol cellulose, and cellulose glycolic acid prepared respectively from methyl sulfate (or chloride), from ethylene oxide (or chlorohydrin), and from sodium monochloroacetate are dispersible in water and have found use as sizing and finishing agents in the textile industry. (See also CELLULOSE: *Uses of Cellulose and Derivatives*.)

B. OTHER NATURAL PRODUCTS

1. Casein Plastics.—Casein (the protein derived from milk) was condensed with formaldehyde by A. Spitteler and W. Kriscche in 1897 to form a tough, insoluble mass that could be fabricated readily. Production of this plastic was begun shortly after 1900 in Germany and France and in 1914 in England under the name of Galalith (milkstone). Manufacture was undertaken in the U.S. in 1919. At the time the casein plastic came into prominence it possessed an immediate advantage over competitive products in that it was much less flammable than nitrocellulose and could be fabricated into objects of lighter colour than was possible with the phenolic resins. When an attempt was made to introduce the casein plastic into the United States, its limitations became apparent, especially under the country's extremes of humidity. The product was wholly unsuited for electrical fixtures and other applications requiring some degree of dimensional tolerance. The limitation of the composition, along with the advent of synthetic resins that could be handled more rapidly yet did not possess the limitations inherent in the protein plastic, gradually restricted the use of casein plastic until the only large outlet for the product was in the manufacture of buttons from alum-hardened casein. (See also CASEIN: *Uses*.)

2. Shellac.—This natural resin finds some use in the manufacture of molding compositions. In many respects shellac is an ideal plastic binder for certain types of electrical equipment and for communication instruments. The resin is often used by itself as well as in combination with such fillers as flaked mica and asbestos.

C. SYNTHETIC RESIN PLASTICS

Synthetic resins can be grouped in many different ways, but one generally accepted classification divides them into thermoplastic and thermosetting types. The thermoplastic resins are characterized by their ability to remain plastic after numerous heating treatments, while the thermosetting, or thermocuring, resins, when once heated, are converted to a cured or infusible form that cannot be fused again without serious chemical degradation. From the molecular structural standpoint, the thermoplastic resins are characterized by molecules that are essentially linear or threadlike in form, while the thermosetting resins consist of molecules that are considered to be linked three-dimensionally into a network arrangement. Resins may also be classified according to the chemical means employed to effect reaction. Certain resins formed without the elimination of volatile components are generally referred to as the polymerization type. Where volatile ingredients such as water and alcohol are formed during the resin preparation, this type of product can be considered a condensation resin. When the chemical and physical types are superimposed, it is possible to have the grouping:

1. Thermoplastic condensation resins
2. Thermoplastic polymerization resins
3. Thermosetting condensation resins
4. Thermosetting polymerization resins

The equations leading to the formation of these various types may be written schematically as follows:

and, by altering the thickness and pigmentation, reflection and transmission can be modified at will. The molded product is used in the manufacture of buttons, wall plates, instrument dials, display boxes, dress accessories, and housings of all types.

The resin in solution possesses many other applications. Resin solutions are used in the preparation of cements that can be hardened hot or, through the proper addition of catalysts, may be set cold. When the water-soluble resin is suitably dispersed in organic solvents, it forms the basis of a very important class of resin finishes and enamels for metal coating. As an impregnant for wood veneer, the water-soluble condensation products serve both as a binder and a protective coating. Since the resin is colourless, the cured resin materially enhances the beauty of the wood. The solutions are also used to treat textiles in order to control their shrinkage and render them crease or crush resistant.

In the manufacture of laminated stock, sheets of absorbent paper are impregnated, dried, and assembled to appropriate thickness and then heated between platens to yield a sheet stock that is used in lighting reflectors, signs, wall panels, table tops, and decorative murals.

Melamine-Formaldehyde Resins.—Prior to 1939 melamine was available only in limited amounts at \$40 a pound. Although the compound was rare, it had been known for more than 100 years and had been first prepared in 1834 by Justus von Liebig. After new industrial processes became available in 1939, melamine was made in ton quantities, and like urea it is secured from the air. Combining nitrogen from the air with calcium carbide yields calcium cyanamide, which can be hydrolyzed to cyanamide, which in turn can be dimerized to dicyandiamide. Under high temperature and pressure, dicyandiamide is transformed to melamine, an extremely stable substance containing only carbon, hydrogen, and nitrogen. These reactions can be represented by the following chemical equations:

When condensed with formaldehyde, melamine forms products that in superficial respects resemble the condensation products of urea, but, where only mono- and dimethylolureas have been prepared, a much wider number of the initial melamine-formaldehyde condensation products are known. Di-, tri-, and hexamethylol melamines have been prepared.

The melamine resin can tolerate fillers, such as asbestos and other minerals, that cannot be used with the urea condensation product. Because of their excellent heat and arc resistance, good dielectric strength, and low water pickup, mineral-filled melamines suitably modified with other resins were used in ignition systems.

Cellulose-filled melamine plastics have been used in many of the applications already discussed for the urea resins, but since the melamine resin is more resistant to high temperatures, to boiling water, and to more alkaline solutions, and since it does not retain food odours, it is particularly useful in tableware. The melamine resin possesses extreme hardness; this, together with its good colour and abrasion resistance, makes it an invaluable material for surfacing laminated assemblies. Translucent moldings may be made, for example, in button manufacture.

Anhydrous Thermosetting Resins.—The thermosetting resins used for laminating and molding depend on the loss of water to become insoluble. To reduce the water content to the smallest possible amount, the resin is carried to an advanced stage of condensation in which considerable heat and pressure must be utilized to cause the resin to flow sufficiently to fill the mold. During World War II, new types of products appeared that did not require the loss of water to bring about insolubility and infusibility of the resin. These compositions have been referred to as anhydrous thermosetting resins and solventless varnishes, while the process has been called low-pressure, or contact, molding. They belong to the thermosetting polymerization type of resins. Irrespective of the name, all of these resins have one characteristic in common: the polymerizable molecules possess a plurality of unsaturated groups and undergo reaction to insolubility quickly and exothermically without the evolution of low-molecular-condensation residues. The unsaturation can be introduced into the initial molecule by the incorporation of either unsaturated acid residue, or unsaturated alcohol residues, or both. The polymerization is generally catalyzed by peroxides. The physical state of the anhydrous thermosetting resins can be varied within wide limits; some are thin fluids, others viscous liquids, whereas still others are solid or greaselike in consistency. Since only low pressure is required in fabrication, comparatively inexpensive molds can be utilized. In many instances the fluid-molding technique may be employed for making complex shapes; this procedure depends on delivering pressure uniformly over a large area through the use of rubber bags, and by such means large structural parts of airplanes and boats have been built. The most spectacular development in this field is the fibre-glass-reinforced automobile body. In certain respects the high strength and the low weight of the plastic combined with its ability to recover practically undamaged from impacts and its higher resistance to corrosive atmospheres and moisture penetration have been assets. In large-scale production, however, the assembly could not compete with steel construction. Some efforts have been directed to the use of these reinforced resins as reinforcing agents in the manufacture of plastic pipe and in the manufacture of equipment for use in the chemical process industries. Here again the outstanding advantage arises from corrosion resistance. When such rigid sheets of plastics are laminated into a cellular or

honeycomb core, the highly rigid and lightweight combinations produced possess good strength and insulating characteristics. Large volumes of this resin are utilized in the manufacture of boats, in construction, and in transportation equipment.

The anhydrous thermosetting products are frequently referred to as polyester resins since ester groups are present in the molecule. Another product designated as a polyester is the polyethylene glycol terephthalate. Again, ester linkages are present in the molecular pattern, but the physical properties of the polymer are very different. Being of much higher molecular weight and crystalline in structure the product can be oriented into fibres and into sheet stock of exceptional clarity and strength. Polycarbonates likewise fall into the class of polyesters. Polyarylcarbonates, formed by the condensation of bisphenol A (4, 4'-isopropylidenediphenol) through reaction with phosgene (carbonyl chloride), yield high-molecular-weight thermoplastic compositions having exceptionally good dimensional stability and mechanical properties. The high impact strength of this polycarbonate resin is employed wherever exceptional toughness is necessary. The electrical properties are such that it finds application in electrical connectors, coil forms, and terminal blocks.

Epoxy Resins.—As the name implies these resins have as their chief functional group the epoxide linkage. When first produced commercially, these resins were prepared by condensing bisphenol A (as a salt) with epichlorohydrin. Later the reaction was extended to a series of products derived from resorcinol. These resins may be cured through the use of polyamines, as well as with acid anhydrides, to yield infusible resins without the loss of volatile components. Initially, these resins were used in surface coatings but later found wide application in lamination with glass fibres, as well as in casting, potting, capsulation, and in embedments. When used as molding compounds with various fillers very low pressures must be used, and the molds must be tight to prevent excessive flashing.

2. Thermoplastic Resins.—Vinyl Resins.—As noted above, acetic anhydride is required in the manufacture of cellulose acetate. Following World War I various methods were investigated for converting the acid to the anhydride since it was anticipated that large quantities of this cellulose plastic would be required in the manufacture of fibre, film, and safety glass. Among the methods investigated was the reaction of acetic acid with acetylene to form ethylidene diacetate, which in turn could be decomposed to acetic anhydride. In conducting the reaction between acetylene and acetic acid, investigators obtained substantial quantities of an organic liquid that had a boiling point too low to be the desired product. This liquid was monomeric vinyl acetate. Although the investigation was directed primarily to the preparation of an acetylating agent, vinyl acetate was in time destined to be the basis of the manufacture of most of the plastic used in safety glass.

Polyvinyl Acetate Resins.—The transformation of vinyl acetate ($\text{CH}_2=\text{CH}-\text{O}-\text{CO}-\text{CH}_3$) to a safety-glass interlayer did not occur all at once, however. Manufacture of the early product was difficult because little was known concerning the chemistry of transformation of a vinyl monomer to its polymer. Moreover, the early development was hazardous from a commercial standpoint since there were no uses for such a resinous product. It was first investigated as a shellac sub-

stitute, but its remarkable adhesive properties, when hot, made it invaluable for uniting many diverse materials such as cloth, paper, leather, wood, and glass. Compounded with fillers, glycerin, sugar, and flavouring, polyvinyl acetate makes a chicle substitute in the manufacture of chewing gum. Hydrolysis of polyvinyl acetate causes cleavage of the ester grouping, resulting in the formation of polyvinyl alcohol,

a resinous polymeric alcohol that forms viscous solutions in water and finds some utility as a thickening agent for emulsions and in the preparation of plastics that, although sensitive to water, are highly resistant to oils. Polyvinyl alcohol can be spun into a fibre, and, although the fibre is soluble in water, special uses can be made of this solubility in the weaving of sheer laces; fibres of polyvinyl alcohol and any other fibre can be woven and the synthetic water-soluble fibre dissolved, leaving a sheer fabric. The major shortcoming appears to be in lack of heat resistance. On the other hand, the dry tenacity of the product is outstanding.

Many chemical transformations of polyvinyl alcohol are possible. It can be condensed with other low-molecular compounds, particularly aldehydes, to form new resinous materials. Condensation with formaldehyde, acetaldehyde, and butyraldehyde results, respectively, in polyvinyl formal, polyvinyl acetal, and polyvinyl butyral. The polyvinyl formal finds use as a coating resin for electrical insulation; the acetal possesses potentialities as a photographic film base and as an injection-molding material; but it is the butyral that is the most useful, and as much as 100,000,000 sq.ft. have been produced annually for safety-glass manufacture. The resin when suitably plasticized yields a tough, high-impact film that maintains its properties at low temperature, and when laminated between glass it produces a composite assembly that displays little tendency to splinter on impact.

Polyvinyl Chloride Resins.—Vinyl chloride is a gas at room temperature and can readily be prepared from either ethylene or acetylene. Addition of hydrogen chloride directly to acetylene yields the monomer, or ethylene can be chlorinated and dehydrohalogenated to vinyl chloride. The polymerization was extensively studied by I. Ostromislensky, who sought in 1916 to dehalogenate the polymer to a rubberlike substance. Polyvinyl chloride was transformed to a rubber substitute about 20 years after these basic investigations but by an entirely different procedure.

Polymeric vinyl chloride, $-(\text{CH}_2-\text{CHCl})_n-$, is practically infusible and for a long time proved to be a rather intractable substance. In efforts to plasticize the product it was milled and compounded with polyvinyl acetate, mentioned above, but with no great success until it was found that by mixing the ingredients prior to polymerization and then chemically combining the two materials into a polymeric structure, it was possible to achieve in this conjoint polymer, or copolymer, a new type of product that was easier to handle and one that could be further flexibilized through the addition of high-boiling liquids and plasticizers. By varying the ratio of acetate to chloride, resins of varying plasticity and stiffness can be secured.

Intensive investigations were made into the nature of plasticizing methods and techniques of direct plasticizing of vinyl chloride without the necessity of copolymerization. It was generally conceded, however, that the copolymer is more amenable to plasticization by a larger number of widely diverse liquids than is the unmodified polymer. Both types, however, have found extensive use as sheet stock, as wire insulating compounds, and as substitutes and replacements for rubber. Since these polymers possess considerable amounts of chlorine, they will not support combustion and they therefore possess distinct advantages in wiring where nonflammability is of importance. The halogen, however, is labile, and, when the resin is exposed to heat or to ultraviolet light, loss of hydrogen halide occurs, resulting in discoloration. By dry spinning the vinyl chloride-acetate copolymer, it is possible to produce filaments that can be woven into chemically resistant fabric. In Germany fibres were fabricated directly from polyvinyl chloride.

High-speed photograph shows path of water-filled bottle when dropped 20 ft. and its degree of elastic recovery

Polyvinylidene Chloride Resins.—By doubling the amount of chlorine in vinyl chloride, a new chemical entity, vinylidene chloride, is obtained. Because of the symmetrical arrangement of the chlorine atoms in polyvinylidene chloride, $-(CH_2-CCl_2)_n-$, the polymer is crystalline, and advantage can be taken of this crystalline characteristic to form oriented filaments and tubing. Such oriented forms have molecules arranged in an ordered manner with the result that in the direction of orientation the product is very strong. When extruded, quenched, and drawn, the polyvinylidene chloride makes an excellent substitute for reed and rattan and a corrosion-resistant substitute for insect screening; in the form of tubing, the resin can be used to pipe many corrosive chemicals.

Acrylic Resins.—The term acrylic resin covers not only the acrylic esters but also the polymerizable derivatives of both acrylic and methacrylic acids as well as the acid chlorides, nitriles, amides, and substituted amides. Acrylic derivatives generally involve cyanide in their synthesis, but investigations indicate that, at least in the case of the acrylic acid derivative, there may be an alternative procedure involving carbon monoxide (in the form of a metallic carbonyl) and acetylene. Considerable investigation was also undertaken in an attempt to prepare acrylic esters from natural lactic acid derived from milk, but it remained to be demonstrated whether the natural lactic acid could compete with the synthetic product. The names of Otto Röhm and Rowland Hill were associated with the preparation and polymerization of acrylic and methacrylic esters, respectively.

From the standpoint of plastic molding, methacrylic esters are preferred, since they are harder and more rigid than the corresponding acrylic esters. By changing the type of alcohol used in esterification of the original monomeric ester, it is possible to modify the hardness of the resulting polymer. Polymethyl acrylate is tough and rubbery; polyethyl acrylate is softer and more rubbery; polybutyl acrylate is sticky. Continuing up the homologous series of alcohol esters, the polymers become softer and more plastic until at polyoctyl acrylate it is found that the polymer is almost liquid in consistency.

Polymethyl methacrylate,

is the hardest ester in the methacrylate series, and, as in acrylates, introduction of long-chain alcohols into the ester lowers the softening point of the plastic. Some idea of the relative hardness is seen in the fact that polyamyl methacrylate is about as hard as polymethyl acrylate. While polymethyl methacrylate is the preferred resin for injection molding and plastic applications, it was found that cyclohexyl methacrylate is superior for lens casting, since this liquid undergoes less shrinkage during polymerization than does the methyl ester. Cyclohexyl methacrylate polymer, together with styrene resin, was used in combination in the preparation of plastic achromatic lenses.

Without doubt the largest single outlet for the methyl methacrylate resin has been in sheet form for windows in aircraft, particularly military aircraft. The resin was cast in glass molds, and the finished sheet could then be "post-formed" to a wide variety of shapes necessary for blisters, noses, cockpits, windshields, and canopies. The high clarity of these plastics, as well as the ability to transmit or "pipe" light, also favoured their use in surgical instruments, highway reflectors, and edge-lighted advertising displays. Transparent sheeting in oriented form also is used in motorcycle windshields, instrument windows, glazing, patio shelters, partitions, and mobile home windows. Large moldings of methyl methacrylate resins are used in transilluminated signs.

Whereas styrene was copolymerized with butadiene to form a general-purpose rubber, acrylonitrile ($CH_2=CH-CN$), the nitrile of acrylic acid, was copolymerized with butadiene to yield a special oil-resistant rubber extensively used where rubber had to be in contact with gasoline and other hydrocarbon liquids. Acrylonitrile forms conjoint polymers with many other vinyl compounds such as acrylic esters and styrene, but from all indications it prom-

ised to play its most important role as a polymer in the form of a synthetic fibre.

Polyamides.—By the condensation of diamines and dibasic acid, linear condensation products may be formed, and by varying the nature of the acid and the amine it is possible to produce products that are hard and tough or soft and rubbery. These linear condensation products are referred to as polyamides

Polyamides are most generally known in the form of fine and coarse filaments in such articles as hosiery, parachutes, bristles, and brushes. As has been pointed out, however, high-molecular-weight organic resinous compounds of certain types can be converted into fibres. The polyamides were first offered commercially in the form of filaments but were later directed to the molding trade, particularly toward the injection-molding field where their toughness and ability to flow around complicated inserts are prime considerations. Polyamides, particularly those derived from primary amines, are characterized by a high degree of crystallinity, whether in the form of filaments or as moldings. Under stress, orientation of molecules begins to occur and this orientation continues until the specimen is drawn to about four times its initial size; although this property is of outstanding importance in filaments, it has more limited utility in molded articles. The resin exhibits a sharp melting point and on melting is more liquid and plastic than conventional resinous materials. The fluidity is both an advantage and a disadvantage: the high fluidity necessitates the use of specialized equipment, but on molding there is no need to use excessive pressure in injection molding, since the liquid resin transmits its pressure onto the molded specimen hydrostatically.

Inasmuch as adipic acid and hexamethylene diamine are the ingredients most often used in nylon synthesis and since both of these ingredients contain six carbon atoms, this product has been referred to as nylon 6-6. Another variety of nylon can be made from amino caproic acid; this polymer is referred to as nylon 6. However, a preparation of nylon 6 can be effected much more easily through the use of caprolactam. Extensive facilities are available both in Europe and in the United States for the manufacture of this polymer from caprolactam. (See also FIBRE.)

Caprolactam is a 7-membered heterocyclic ring. A 5-membered ring has been polymerized to a high-molecular-weight substance, polypyrrolidone, or, in the alternative designation, nylon 4.

A product somewhat similar to the polyamides, manufactured in Germany during World War II, utilized isocyanates, particularly the diisocyanates. Reaction of these unsaturated compounds with glycols yielded polyurethanes

which could be fabricated into bristles. A wide variety of other urethane products has been derived from isocyanates. When reacted with the appropriate alkyds, foamed resins are produced that have wide utility in the manufacture of laminates, upholstery, and in insulation. Reacted with another variety of alkyds, these same isocyanates yield synthetic rubbers having unusual abrasion resistance. Other uses for these isocyanate products are being discovered.

Polymers from Cycloxabutanes.—From pentaerythritol can be prepared a cyclic monomeric chlorinated ether that can be polymerized to a high-molecular-weight plastic containing a fair proportion of halogen. Because of the position of the chlorine in the polymer molecule, it is difficult to remove and consequently the product possesses unusual stability. Inasmuch as the groups are symmetrically positioned in the polymer, the product is crystalline and capable of being drawn.

Polystyrene Resins.—That styrene, or vinylbenzene, would polymerize has been known for a long time. The designation vinylbenzene ($CH_2=CH-C_6H_5$) immediately relates it to the other polymerizable vinyl compounds, such as vinyl chloride, fluoride, and acetate. The designation styrene arose from the fact that this liquid was first prepared by heating the natural resin storax. The first patents on the possible uses of styrene were taken out by F. E.

Matthews in 1911. Monomeric styrene is present in the light oils of coal-tar manufacture, and, although extensive investigations were undertaken to remove styrene from this source, the processes proved too costly and could not compete economically with the synthetic methods. In order to secure a satisfactory plastic out of styrene, it is necessary that a highly purified product be subject to polymerization. Where the monomeric styrene is of inferior quality, the resulting resin is too brittle, and on aging the surface of the plastic becomes covered with fine hair lines similar in appearance to those appearing in an unfilled urea-formaldehyde resin. By using a reaction discovered by P. E. M. Berthelot in 1869, it was found that by dehydrogenating ethylbenzene catalytically at elevated temperatures and fractionating the resulting mixture, it is possible to secure a product that on polymerization under appropriate conditions yields a polymer possessing valuable chemical and physical properties. Chemically, the resin is highly resistant to both weak and strong acids, although oxidizing types of acids may lead to some discoloration. Alkalies and the lower alcohols do not attack the polymer, and the water absorption of the resin is extremely small. The resin can be dissolved in coal tar and in chlorinated solvents. In electrical characteristics, the plastic possesses an extremely low power (or loss) factor, and, when the resin is properly prepared, this power factor remains substantially unchanged over a wide range of frequency. The low power factor combined with low water absorption makes polystyrene an ideal material for various electrical and electronic applications. The presence of a multiplicity of aromatic rings in the polymer renders the product responsive to temperature, with the result that the resin can be handled expediently by the injection-molding technique. Among the noteworthy applications of this plastic is the fabrication of battery boxes, ranging in size from those employed in a small automobile to the type that is ordinarily used in portable radio sets. It has found utility in manufacture of condensers, tube sockets, coil forms, and switch plates. As a copolymer with divinylbenzene, the resin was employed for certain radar applications that involved operating temperatures higher than could be tolerated with polystyrene. The monomer was also cast directly for certain optical parts such as prisms and lenses.

Since polystyrene possesses a high dispersion value, it could be combined with polycyclohexylmethacrylate to make corrected plastic achromatic lenses.

One of the limitations of polystyrene for many applications is its inability to tolerate excessive heat; and although the modification with divinylbenzene increases its resistance to heat distortion, it does so at the expense of moldability. In order to increase the heat resistance of polystyrene and maintain moldability, the monomer has been copolymerized with various nitrogen-containing compounds such as acrylonitrile, fumaric nitrile, and vinylcarbazole. The increase in softening point is attained at the sacrifice of colour.

Later developments included the so-called ABS polymers, in which acrylonitrile, butadiene, and styrene are reacted simultaneously. The acrylonitrile-styrene copolymers are likewise prepared in substantial volume. In addition, styrene-methacrylate copolymers were projected into fields where unmodified methacrylate polymers dominated, such as in signs and automotive parts.

Extensive investigation was carried out in the direction of introducing various groups into the styrene nucleus in an attempt to reduce heat distortion directly. One of the methods that proved successful involves the introduction of multiple halogens into the aromatic nucleus. Another method of securing styrenelike plastics having softening points above that of boiling water involves the use of ring-substituted methyl groups in the monomer. By introducing methyl groups into the benzene nucleus of the monomer, the properties of the resulting resin, on polymerization, can be modified. Two syntheses based on alternative isomers have been employed commercially. One procedure, based on the conventional dehydrogenation of the appropriate methyl ethyl benzene, yields a *meta-para* mixture; the other process involves the decomposition of diaryl ethanes, permitting the formation of *ortho*-methyl styrenes. The presence of a methyl group, *ortho* to the vinyl, imparts important heat-resistant characteristics to the fin-

ished polymer; the composition comprising 67% of *para* and 33% of *ortho* yields derivatives, which, on injection molding, remain stable in boiling water.

Acetal Resins.—Through the direct polymerization of highly purified formaldehyde it is possible to secure an unbranched polyoxymethylene comprising more than 1,000 formaldehyde residues in the chain. A polymer thus constituted has, because of its symmetry, high crystallinity and a high melting point. High strength, rigidity, good resilience, and toughness, together with low water absorption, make this plastic extremely versatile in the fabrication of mechanical parts, appliances, and automotive items. Because of the crystallinity this acetal resin is unusual among thermoplastic substances in being resistant to a wide variety of organic liquids. At room temperature no common liquid dissolves the resin. This characteristic permits the plastic to be used without danger of staining by either food or industrial materials. The same statement cannot, however, be made with respect to its reaction with strong acids or bases.

Stereo Polymers.—In the early 1950s Karl Ziegler (*q.v.*) of the Max Planck Institute for Coal Research at Mülheim, Ger., studied the polymerization of ethylene using organic compounds of aluminum as catalysts. Under certain reaction conditions it was possible to polymerize ethylene even at atmospheric pressure. Subsequently, the Italian firm named Montecatini secured licenses under the Ziegler patents, and Giulio Natta (*q.v.*) at the Polytechnic Institute of Milan extended the use of these and related catalysts to the polymerization of *alpha* olefins. Eventually, these systems, known as the Ziegler-Natta catalysts, comprised a wide variety of halides of transition elements for use in polymerization. Somewhat similar investigations were carried out simultaneously by various firms in the United States. Consequently, there developed a wide spectrum of substances that may be used to polymerize not only ethylene but also other hydrocarbons, such as propylene, butadiene, styrene, and a variety of stereospecific polymeric substances.

Certain types of structures in chain molecules permit an alternate steric arrangement. Isomerism involving the double bond, such as the *cis-trans* isomerism, was known to exist in natural products, and it has been known for a long time that the physical properties of balata and rubber differ because of different arrangements of the double bonds in the otherwise similar molecules. Similarly, in condensation polymers, *cis* and *trans* isomers could be produced by condensing maleic and fumaric esters with appropriate polyhydric alcohols.

Another type of stereo isomerism results when different atoms or groups are attached tetrahedrally to a carbon atom. If the two parts of the main chain attached to any carbon atom are structurally nonequivalent, the isotactic structure comprises those polymers in which the basic repeating unit appears to have all of the substituents on the same side of the main chain. Syndiotactic polymers comprise those systems where the substituents alternate on both sides of the main chain.

Isotactic

Syndiotactic

The use of these novel catalysts secures through positioning a symmetry that results in products possessing much higher melting points. These catalysts also have been utilized with diolefins yielding, under polymerization conditions, a different type of symmetry in the diene polymer. With isoprene it is possible, utilizing the Ziegler-Natta catalysts, to arrange a very large proportion of the double bonds in a *cis* position, yielding a synthetic rubber that closely simulates the physical and chemical properties of that obtained from the rubber tree *Hevea brasiliensis*.

Polypropylene.—The development of crystalline high-molecular-weight polypropylene came out of the catalytic studies designed

for the low-pressure polymerization of ethylenes as noted above. These heterogeneous metal alkyl substances are capable of directing the polymerization of substituted olefins to yield an ordered polymer.

The development of commercial processes involving the formation of crystalline polypropylene was expensive. Where there is a high portion of isotacticity a more ordered crystalline polymer is obtained, characterized by greater hardness, toughness, and higher melting points. Polypropylene is one of the lightest of the plastics; its low density, together with good physical properties, means high strength-to-weight ratios in finished parts.

Polyvinylcarbazole Resins.—Reaction of acetylene with carbazole yields vinylcarbazole

which can be converted to a plastic possessing high heat resistance and excellent electrical properties; but the brittleness of the product limits its uses to specialized industrial applications.

Polyethylene Resins.—Although ethylene is the simplest unsaturated compound, it proved to be one of the most difficult to convert into a high-molecular-weight polymer, with extremely high pressures and moderately high temperatures required to effect conversion. As might be predicted from its structure, polyethylene, $-(\text{CH}_2-\text{CH}_2)_n-$ is completely nonpolar and possesses a low power factor and a low dielectric constant. Being highly symmetrical, it is also crystalline. In common with other crystalline polymers, thin sheets of the resin exhibit high resistance to penetration by water vapour.

At ordinary temperatures the resin is highly resistant to attack by organic and inorganic reagents. At moderate temperatures the resin can be dissolved in certain organic liquids and such solutions can be applied as a coating, but satisfactory results are obtained only by keeping the coated object in a heated condition until the solvent has evaporated. Polyethylene, however, can be applied more easily by direct extrusion of the molten plastic. It proved suitable for insulating high-frequency and high-voltage circuits.

A type of polyethylene that takes on characteristics of a more rigid plastic is frequently referred to as "linear" polyethylene. That such linear products were possible was known for a long time. These products had been prepared by the decomposition of diazomethane, but to prepare such materials directly from ethylene was recognized as a major achievement. Such linear products possess a higher softening point that permits sterilization, a procedure that was impossible with the earlier type.

By combining covalent and ionic bonds in a thermoplastic, a family of polymers known as ionomer resins has been produced. These substances are based on the observation that by introducing ionic forces in a semicrystalline polymer, such as polyethylene, visible crystallinity is decreased, while the modulus of elasticity and resistance to oil and solvents are markedly increased. The covalent bonds, being intramolecular, unite the atoms of the polymer chain, while the ionic bonds are intermolecular and act between chains. These ionic interchain lengths toughen the polymer without destroying its ability to be fabricated as a plastic.

Polyisobutylene Resins.—Isobutylene is a hydrocarbon boiling at about -5°C , and when dimerized it can be converted by reduction to 2-methylheptane. By conducting the polymerization at very low temperatures, using boron fluoride as a catalyst, a high-molecular-weight product

is formed. This polymer is rubberlike, but, inasmuch as the material is saturated, it cannot be vulcanized. By conducting the polymerization of isobutylene along with a diene such as butadiene, isoprene, or dimethyl butadiene, unsaturated residues are introduced into the polymer. These residues can act as nuclei for vulcanization with sulfur.

Polyvinylpyrrolidone (PVP).—The polymer secured from N-vinyl-2-pyrrolidone is a water-soluble product, possessing many unusual characteristics and having a wide variety of pharmaceutical applications including that of blood plasma extender. The product is used in the United States chiefly in hair-spray lacquers and in detergents. The polymer has a high affinity for many dye-stuffs and in many laundering applications will prevent the bleeding of migrant colours from one garment to another. When hair is placed in contact with aqueous solutions of polyvinylpyrrolidone a certain amount of polymer enters into the hair shaft. Subsequent rinsing will not remove all of the polymer, leaving the hair with an improved appearance both from the standpoint of clarity and of natural colour. A number of preparations employ PVP as a retardant vehicle for drugs since it permits the drug to remain in the body for a longer period.

Polyvinyl Methyl Ether (PVM).—Another high polymer possessing water-soluble characteristics and simultaneously dispersible in a number of organic liquids is the polymer secured from vinyl ether. Like PVP it is a derivative of the high-pressure synthesis of acetylene. The direct addition of methanol to acetylene under pressure using appropriate catalysts yields a monomer. When alcohols other than methyl are used with acetylene similar vinylization occurs yielding vinyl alkyl ethers. If the alcohol is long enough, such as stearyl alcohol, no excessive pressure is required to carry out the reaction. These vinyl ethers will polymerize among themselves or with other vinyl materials. One product used extensively as a water-soluble colloid is the copolymer of vinyl methyl ether with maleic anhydride, which has been designated as PVM/MA. Inasmuch as acidic groups are still present in the polymer, a number of esters with widely varying physical characteristics may be prepared.

Polyacrylamide.—Still another polymer possessing water solubility in its resinous plastic form is polyacrylamide. The amide linkage is capable of reaction with formaldehyde, yielding an intermediate that can undergo further condensation reactions.

Perhalogenated Plastics.—Several references can be found in the patent literature for the preparation of polymeric materials that possess only carbon and halogen in their molecular structure. One of the perhalogenated products, polytrifluorochloroethylene, $-(\text{CF}_2-\text{CFCl})_n-$, is described in a patent issued to F. Schloffer and O. Scherer (1934), while another patent, that of R. J. Plunkett in 1941, refers to tetrafluoroethylene polymer $-(\text{CF}_2-\text{CF})_n-$. The latter product was produced commercially in limited quantities and found its chief use in the preparation of corrosion-resistant gaskets. Polymeric tetrafluoroethylene is a remarkably stable substance and is insensitive to all organic and inorganic liquids. As would be expected from its symmetrical structure, the polymer is crystalline and the resin on heating undergoes a phase transition at about 327°C , where the moldings become transparent and the tensile strength decreases markedly. Other perhalogenated plastics utilize perfluoropropylene as a reactive monomer.

3. Foamed Plastics.—Under appropriate conditions almost any thermosetting or thermoplastic resin can be converted into a foam. While foam rubber anteceded foamed plastics, there is now available a number of products, such as foamed vinyl, expandable polystyrene, cellular polyethylene, foamed phenolics, foamed silicones, cellular cellulose acetate, and urethane foams. A distinction is made between the closed-cell foam and the open-cell variety. The open-cell foams are produced by incorporating an inert gas with the resin under pressure and then releasing the mixture to the atmosphere and curing the resulting foam. Closed-cell foams are produced by incorporating a blowing agent that decomposes at the fusion point, releasing gas during the gelling and fusion.

The urethane foams are formed by reaction of hydroxyl-rich materials and polyisocyanates, usually tolylene diisocyanate. While initially the main hydroxylating agent was a polyester, polyethers have come into extensive use. It is claimed that the polyethers give a more flexible urethane that is more desirable in cushioning. Through the proper choice of proportions and ingredients the foamed urethane may be flexible or rigid and have applications in furniture, transport, toys, packaging, thermal installations, air-

craft, and as sponges. Rigid polyurethane foams are being used to make plastic boats and to fabricate beams and panels for buildings.

PLASTIC SURGERY is that specialty of surgery which concerns itself principally with the improvement in appearance or function of the external tissues of the body. It is a formative or constructive discipline making use of the readjustment of local tissues or the transfer of tissues from a distance to effect a desired change for the better appearance of parts of the body. Early in its development, plastic surgery was limited to correction of facial deformities, but its scope has been expanded to include correction of defects of all external parts and, in a more limited fashion, restoration of function, as of the hands, not necessarily associated with abnormal appearance.

History.—Probably the earliest use of the term plastic surgery was that by Edward Zeis, author of the *Handbuch der Plastischen Chirurgie* (1838). But some of the techniques employed had their origin long before the publication of Zeis's book. As early as or earlier than 800 B.C. the Hindus restored missing facial features. For instance, the caste of potters advanced the tissues of one or both cheeks toward the midline of the face for the reconstruction of the nose; the need for this arose from the practice of slicing off the nose as punishment for various offenses. Some discussion of the same general type of surgery as that used by the Hindus was contained in Celsus' description of plastic procedures in his *De medicina* (1st century A.D.). Galen (2nd century A.D.) also was acquainted with these procedures. Thereafter, it was not until the middle of the 15th century and the work of Branca in Sicily that further development of plastic surgery occurred. Instead of using facial tissues for reconstructing the nose, Branca substituted the use of skin and fat from the arm. In 1597 Gaspar Tagliacozzi prepared a systematic treatise on plastic surgery. Then its development ceased again until the 19th century.

The first half of the 19th century was marked by development and refinement of the established principles underlying the transfer of tissue still partially supplied with blood (pedicled flaps); the second half was marked by expansion of the newly evolved

technique of transplantation of skin and other tissues completely separated from their original blood supply (grafts). One of the earliest descriptions of the use of grafts was that by J. Mason Warren of Boston in 1843. In fairly rapid succession, Jacques Louis Reverdin (1869), L. L. X. E. Ollier (1872), J. R. Wolfe (1876), Karl Thiersch (1886) and Wilhelm Krause (1893) elaborated and refined the principles involved in the free and unattached transfer of skin grafts, so that by the beginning of the 20th century grafting was a well-recognized plastic surgical procedure. With the development of the Padgett dermatome, a mechanical device for cutting thin pieces of skin from a large area, in 1939, it became possible for surgeons to make use of skin grafts readily.

Techniques.—Autografting.—The use of pedicled flaps and of free grafts has as its main purpose the addition of tissues to the region undergoing repair. Sometimes there is no need to supply new tissue; rearrangement of what is already there may be sufficient. The Z-plasty is one such local rearranging technique. In this, width may have to be sacrificed for length, but by so doing an improvement in appearance or function may be attained. Sometimes simple removal of tissue may be all that is needed to provide the desired effect. Very commonly the plastic surgeon employs two, three or all four of these major techniques.

The employment of a free graft entails relatively less surgical manipulation than that of a pedicled flap, for the tissue is simply removed from one part of the body and then reinserted into or applied upon another. The tissue of a pedicled flap, on the other hand, usually must be prepared for severance from its donor site

ADAPTED FROM M. THOREK, "MODERN SURGICAL TECHNIC," VOL. 1, © 1949

PLASTIC SURGERY OF THE HAND (BACK AND PALM) USING A PEDICLED FLAP FROM THE ABDOMINAL WALL

by a series of incisions which progressively all but encompass the tissue and cause it to become wholly dependent upon the blood supply entering from one retained attachment or pedicle. In this manner a relatively great bulk of tissue can be made to live upon a relatively narrow stalk, and it becomes possible to move one extremity of the flap to a new site while the flap continues to be nourished through its stalk. Once the transplanted portion has healed to the margins of the defect to which it has been transferred, the sustaining pedicle can be divided and the tissue will live from the blood carried into it from the vessels of the recipient area.

The skin employed for grafting may include the entire thickness of the two layers of skin, the external epithelium and the deeper corium, or the skin may be reduced in thickness by inclusion of only part of the corium with the epithelium. The full-thickness graft does not have so good a chance for survival as the partial-thickness graft, but when it survives it retains more normally its original characteristics such as colour and texture and is not so subject to reduction in area. Split-thickness grafts, which have a better chance for survival, undergo more shrinkage and

alteration of their original texture and colour. Full-thickness grafts find their principal use in the replacement of skin of the face, where texture and match of colour with the surrounding normal skin are of paramount importance; partial-thickness grafts are employed on other parts of the body, particularly when extensive areas of skin are needed.

Homografting.—For many years efforts have been made to understand the physiological basis for the maintenance of survival of tissues transplanted from one human being into or upon another. Such tissues, called homografts (as opposed to autografts, or transplants from one part to another of the patient's own body), could be very useful, as for the skin grafting of extensive defects when the patient, for one reason or another, is unable to supply donor skin for himself. Permanent homografting of skin must await elucidation of the means whereby the graft can be induced to remain alive. In spite of their frailty, however, homografts of skin do survive for periods of several weeks, and this makes it possible to apply them, as a purely temporary measure, upon extensive burn wounds merely to obtain provisional coverage while the general condition of the patient improves. (See also TRANSPLANTS, TISSUE AND ORGAN.)

Foreign Bodies as Replacements for Living Tissue.—Although the body usually can provide its own replacements, such as cartilage or bone, for the reconstruction of skeletal defects, there are times when the patient is unwilling to submit to the extra operation necessary for the removal of the graft. Homografts of cartilage or bone can be used, with less chance of success than with autografts, or foreign materials such as various plastics (e.g., polyethylene) may be employed. Indications for the use of foreign bodies are relatively few, because the chance for permanent retention is not great. On the other hand, foreign bodies do find a wide application as external prostheses. Whereas the reconstruction of a major defect of the face from living tissue may be indicated when the patient's life expectancy is considerable, an external prosthesis may be desirable for older persons who might not be willing to devote the time needed for the multiple operative stages necessary to rebuild a complicated anatomical part such as a nose or ear.

Deformities and Defects.—Congenital Malformations.—These constitute a very important segment of plastic surgical practice. Two of the commonest are harelip and cleft palate. Repair of harelip generally is carried out within the first few months of life, not only to restore an abnormal appearance toward normal but also to improve the sucking function. Harelip deformity may be seen as a notching of the vermilion border or may be present as a complete cleft of the upper lip, usually on the left side, but occasionally bilateral or on the right side alone. Both harelip and cleft palate may occur in the same patient, or only one may be present. The time for repair of the cleft palate is often said to be about the age of 18 months, but sometimes it is desirable to wait for several years, in which instance an artificial device may be provided to help separate the nasal and buccal cavities. The aim of surgical repair is to accomplish such separation by eradicating the longitudinal gap in the roof of the mouth, and so to aid in the development of better speech, the control of escape of ingested food via the nostrils, and the reduction of upper respiratory infections. For the maximal benefit from repair of harelip and cleft palate, in some instances a series of operative procedures must be performed.

Burns.—Although minor burns (*q.v.*) can be treated successfully by all surgeons, the techniques of skin grafting play such an important role in the treatment of major burns that plastic surgeons are frequently called upon to care for patients following destruction of extensive areas of skin. Burns usually are classified as first, second or third degree. In third-degree burns the entire depth of skin is lost, and unaided healing can occur only by the slow advance over the wound of skin from the margins of the defect. This process may take weeks, months or even years to be completed, depending upon the extent of the burned area. The patient's immediate welfare may be improved by the application of partial-thickness skin grafts, which reduce the time required for wound healing as well as the amount of residual scarring.

After an interval of many years (approximately 10–40), the scars resulting from unaided healing of large third-degree burns may undergo chronic ulceration, perhaps related to an inadequate blood supply. Such unstable scars are subject to skin cancer. As a consequence, even though third-degree burns may have healed without skin grafting, the plastic surgeon may be called upon years later to excise ulcerated, unstable scars down to normal tissue and to cover the new wound with grafts or even with pedicled flaps.

Another complication of the healing of some third-degree burns is development of contractures. Virtually all scars gradually decrease in length over a period of months or years. This may, in effect, lead to the limitation of motion of joints over which the skin must be able alternately to increase and decrease in length. The inelasticity of a short contracted scar over a joint may very well limit the range of motion of the joint and so interfere with normal usefulness. Seldom is simple excision of the scar sufficient for restoration of function; it is frequently necessary not only to remove the scar but also to add new skin.

Keloids—excessive overgrowths of scarlike tissue at the site of destruction of skin—may follow any deep skin injury, but are most prone to follow third-degree burns in those persons who have the inherent tendency to develop them. Little is known of the underlying reasons for the excessive overgrowth of scar, but the end results can be improved in some cases by plastic surgery combined with the therapeutic influence of X-rays or some other means for lessening the amount of new scar formation.

Psychologic Implications of Plastic Surgery.—In many instances, the deformity or abnormality which is being subjected to plastic surgical repair is gross and obvious to everyone, but in many others deviation from an accepted norm is so slight that an observer might wonder why the patient calls for correction. In addition to the patient's simple displeasure with his appearance, there may of course be economic or sociologic implications when the patient believes that an abnormality is preventing him from securing or holding a specific position or gaining the affection of a specially desirable mate. Many persons, for example, ask for such operations as "face-lifting" so that they may continue to hold jobs in which the appearance of old age is considered undesirable. Under such circumstances as these, recourse to plastic surgery may save the patient much unhappiness.

Although patients may occasionally request alteration of almost any part of the body, the majority of cosmetic surgical procedures are carried out for remodeling of the nose, ears and breasts, and for the removal of wrinkles from the aging face. Sometimes the amount of surgical alteration, as in cosmetic rhinoplasty, may involve the addition or removal of a very small amount of tissue, yet result in a striking change in the patient's appearance.

The Specialty of Plastic Surgery.—Although some of the techniques of plastic surgery are used by many different types of surgeons, surgeons who devote all their time to this type of surgery in the United States usually take the examination of the American Board of Plastic Surgery after prolonged study and hospital training. For the dissemination of new information, the Society of Plastic and Reconstructive Surgery publishes a monthly journal.

PLATA, RÍO DE LA (PLATE RIVER), has two meanings: in the most limited sense, it is a broad estuary, approximately 171 mi. (275 km.) long, located between Argentina and Uruguay and flowing southeast into the South Atlantic; in a more comprehensive sense, it is the mouth of an enormous drainage basin which includes the Paraguay, Paraná and Uruguay rivers and numerous smaller rivers and streams. This basin drains the southern portion of South America, as the Orinoco and Amazon drain the northern. The area covered, 1,679,535 sq.mi. (4,350,000 sq.km.), includes the whole of Paraguay, southeastern Bolivia, most of Uruguay and large portions of Brazil and Argentina, thereby ranking this river system fourth in the world by size. The rate of discharge, however, estimated at 2,800,000 cu.ft. per second, makes this system second only to the Amazon in volume.

The Estuary.—At its upper extremity, where this estuary receives the waters from the great river systems of the Paraná and the Uruguay, the width is 19 mi. The Argentine island of Martín García is located near this extremity and provides a control point for navigation. The estuary gradually widens to 63 mi. (101 km.) at Montevideo and then fans out to 140 mi. (225 km.) at its mouth. Despite the enormous amount of water discharged into the ocean, the Río de la Plata is relatively shallow. The depth of the main channel above Montevideo is 36 ft. The average depth outside the main channel is 10 to 20 ft. Seasonal rates of flow, winds and tide have a considerable effect on the depth. Constant dredging is necessary to keep a 20 mi. side channel, 31 ft. deep, open to the port of Buenos Aires, and to clear other parts of the main channel. Consequently, ships, after entering the Río de la Plata, are restricted to prescribed courses. The bottom is composed of sand and silt. The expanse of low plain or pampas on the southern or Argentine side permits violent winds, known as *pamperos*, to build up and whip the waters of the estuary into violent storms at certain times of the year.

Upper Paraná and Affluents.—The Paraná, meaning "mother

of the sea" in the Guarani language, is the larger and more important of the two river systems which flow into the Río de la Plata estuary. About 1,400 mi. of its estimated 2,796 mi. (4,500 km.) length is above its juncture with the Paraguay river and is known as the Upper Paraná (Alto Paraná). The Paraná is formed by the union of the Paranaíba and Grande rivers at 20° S., these two rivers having traced the western and southern borders of the state of Minas Gerais, Brazil, in their previous course. The Paranaíba originates a few miles from the headwaters of the São Francisco river, but flows in the opposite direction, at first west and then southwest. By the time it joins the Grande it has already received eight sizable tributaries. The Grande originates in the Serra da Mantiqueira, almost within sight of Rio de Janeiro, Braz., and descends in many falls and rapids for about 845 mi. (1,360 km.) to its juncture with the Paranaíba.

A number of Brazilian rivers from the states of Mato Grosso, São Paulo and Paraná empty into the Paraná as it flows generally southwest. Most of these tributaries, such as the Sucuriú, Verde, Pardo, Ivinheima, Amambai and Iquetemí on the west and the

Tietê, rising within the vicinity of the city of São Paulo, the Peixe, Ivaí, Piquiri on the east, are navigable only for short stretches by canoes or small launches and are broken by frequent waterfalls and rapids. The largest of the eastern tributaries is the Paranapanema, which descends 559 mi. (900 km.) from the Serra do Paranapiacaba overlooking the Atlantic ocean.

Small river boats can navigate the upper reaches of the Paraná river in Brazil for 400 mi. between the falls of the Urubupungá and the falls of Guairá (or Sete Quedas). At this latter point, the river has torn a 2-mi. gorge through the red sandstone of the Serra de Maracaju (Serra do Mbaracayú.) The result is a stupendous although not well-known sight. The river, which widens to a 3-mi. lagoon, suddenly becomes constricted between canyon walls only 300 ft. apart. As a result the water boils in deafening crescendo, which can be heard for 20 mi., through several channels and some 18 cataracts in a total descent of approximately 300 ft. There the Paraná becomes an international boundary and serves to divide Brazil and Paraguay for a distance of 130 mi. until joined by the Iguazú (Iguassú) river.

Iguazú.—This river, the most spectacular of the Paraná's affluents, also rises in the Brazilian coastal range, the Serra do Mar, and flows nearly directly west for 430 mi. For its last 75 mi. it divides the Argentine province of Misiones from Brazil. About 15 mi. before it joins the Paraná, the river plunges over an escarpment, which is 2½ mi. in width. The resultant cataracts are among the most famous falls in the world, often compared with the Niagara or the Victoria on the Zambezi. Although most of the

DRAINAGE BASIN OF THE RIVERS WHICH FLOW INTO RÍO DE LA PLATA

escarpment is broken into two descents of approximately 100 ft. each, one mass of water roars 269 ft. down the Garganta del Diablo or Devil's Throat. As many as 275 separate waterfalls have been counted in the dry season, while at flood stage the volume exceeds that of Niagara. (See IGUAÇU.)

From the mouth of the Iguazu to the juncture with the Paraguay, 420 mi. farther on, the Paraná serves as the boundary between Paraguay and Argentina. There are no important tributaries which join the river in this stretch. Near the capital of the province of Misiones, Posadas, 27° 22' S., the Paraná turns westward. The relatively narrow river, 1,500 ft. in width, has cut several channels between high rocky banks, creating large islands in its course, such as Yaciretá, Apipé Grande and Apipé Chica, and Talavera. The current in these channels is strong and the passage is made difficult by rapids such as those of the Apipé. Shortly after these rapids, however, the Paraná escapes from its red sandstone bed, and its flow becomes more leisurely as the river widens. The banks of the river are lower and the bottom is sandy.

Paraguay.—This main affluent of the Paraná is 1,584 mi. (2,549 km.) long. It rises in the Brazilian state of Mato Grosso, near the town of Diamantino, 14° 24' S., not far from the headwaters of the Tapajós and the Xingu, tributaries of the Amazon. It flows first southwest and then south into the morass of Xarayes, which expands into still vaster swamps as the river grows in size. Few streams feed the Paraguay from the west with the exception of the Jauru. There are, however, a number of large shallow lakes to the west of the Paraguay which receive overflow from the morass of Xarayes. Several important affluents swell the Paraguay from the east and drain a vast area of Mato Grosso. These Brazilian rivers, north to south, are the Cuiabá and São Lorenzo, the Taquari, Miranda and Apa, the last serving as a boundary between Mato Grosso and northern Paraguay. In this northern area, the Paraguay is a shallow, sluggish river. During the rainy season, it spreads out for hundreds of miles from each bank, turning the vast swampland between 17° and 20° S. into great lakes. In this Corumbá territory of Brazil, as much as 30,000 sq.mi. (77,700 sq.km.) have been inundated.

South of the mouth of the Apa river, the Paraguay flows through Paraguayan territory. On the west, the vast Chaco jungle and morass is only imperfectly drained by the Pilcomayo and Bermejo rivers and by innumerable smaller streams. Much of the east bank of the Paraguay, in particular the lowland between Concepción and Asunción, is also subject to seasonal flooding. About 250 mi. south of Asunción, the Paraguay merges its slow-moving mass (140 ft. above sea level) with the Paraná river.

Pilcomayo, Bermejo and Salado.—These three rivers, north to south, rise in the Andes and flow southeast in parallel courses. The Pilcomayo, "river of the birds" in Guarani language, descends from its source north of Potosí, Bolivia, 8,000 ft. in 350 mi. to the Chaco plains. The course of the river then loses itself in the Chaco morass and finally wanders in three separate branches to its juncture with the Paraguay opposite Asunción. The main channel, such as it is, marks the boundary between Argentina and Paraguay.

The Bermejo rises on the Bolivian-Argentine frontier. After a rapid plunge to the Chaco lowlands, the river flows in a sinuous course around islands and sandbars which make any estimate of depth meaningless. The current is stronger than that of the Pilcomayo. Much silt is carried in suspension thus originating its name to describe the reddish colour. It has been estimated that this river alone carries off 6,400,000 cu.yd. of soil from the Chaco each year.

The Salado is formed by several rivers which drain the Argentine province of Salta and emerge on the Chaco lowlands. Like the Pilcomayo and Bermejo, the Salado follows no prescribed channel but wanders in a braided pattern across the countryside, particularly at floodtime. The Indian use of such alluvial croplands has been imitated by settlers growing maize, wheat, flax and cotton, although permanent or continuous use of the land is, at best, difficult when irrigated only by such annual floods.

Lower Paraná.—After its juncture with the Paraguay, the Paraná flows slightly southwest until it reaches the city of Santa

Fe and is joined by the Salado river. Then it curves in a gradual arc until at Rosario it is flowing southeast to join the Río de la Plata. The Lower Paraná is entirely within Argentine territory, passing through some of the richest agricultural land in the world. On the east lie the pastoral provinces of Corrientes and Entre Ríos, while on the west is the breadbasket of Santa Fe and northern Buenos Aires.

The Paraná becomes a truly imposing river after it joins forces with the Paraguay. Even at low water, its 800-mi. course to the Río de la Plata is from 2 to 4 mi. wide. Unlike the clear waters of its Brazilian sources, however, it is now tremendously burdened with silt. The Paraguay brings soil from Mato Grosso, while the Pilcomayo, Bermejo and Salado, eating away at the Andes, add tons of alluvium. The western bank of the lower Paraná is a high bluff of red clay rising 25–75 ft. above the river level and is constantly undermined by the current.

The amounts of silt lend themselves to a building as well as a tearing away process. Unlike the high rocky islands of the Upper Paraná, the Lower Paraná is dotted with large, low, often forested islands. During flood season, however, the Paraná may widen to 10 mi. and, in places, even 30 mi., burying islands and overflowing into marginal swamps. The periodic floods as well as the seasonal rise and fall of the water level naturally wreak havoc with islands and channels. Below Rosario, the islands and the main channel are more stable, because the total rise, even of flood waters, is distributed over a wider area and consequently is not as great. The mouth of the Paraná river or the head of the Río de la Plata estuary, until a recent geological period, must have been located much farther inland, perhaps as far as 32° S., near the present town of Diamante in Entre Ríos. Subsequently, silt has built up island structures from the sandy bottom. The clustering of these islands forms a huge delta, 40 mi. wide and 100 mi. long, at the mouth of the Paraná.

The lower Paraná finds its way through the Paraná delta in 11 outlets and several canals. The two principal channels which are used by ocean vessels are the Paraná Bravo with a depth of 36 ft. and the Paraná Guazú with a depth of 20 ft. The depths of the other channels and connecting canals used by coasting craft vary greatly but are announced periodically. Constant dredging is naturally required to keep these channels open for navigation.

Uruguay and Its Affluents.—This is the second major system, 932 mi. (1,500 km.) in length, which flows into the Río de la Plata. Like the Upper Paraná and the Paraguay, the Uruguay originates in Brazil, formed by several small streams which rise on the western slopes of the Serra do Mar, at 27° 09' S. From the south it is joined by the Pelotas, the two rivers serving to divide the states of Rio Grande do Sul and Santa Catarina. After flowing west, the Uruguay turns southwest at its juncture with the Peperi Guaçu, the first sizable affluent to join it from the north. For most of its course, the fast flowing Peperi Guaçu marks the boundary between the Argentine province of Misiones and Brazil. Now the Uruguay serves to divide Brazil and Argentina. A few miles beyond the juncture with the Peperi Guaçu, the river is constricted between rocky walls in the Salto Grande de Misiones, a 2 mi. stretch of rapids with a total descent of 26 ft. in 8 mi. At the cataracts, the river narrows suddenly from 1,500 ft. to an extreme of 70 ft.

Several small rivers join the Uruguay from the west and are navigable in their lower reaches by canoes and small boats. The principal of these, from north to south, are the Aguapey, Mirinay, Mocoretá, which divides Entre Ríos and Corrientes, and Gualeguaychú. The important affluents of the Uruguay, however, come from the east. The Ijuí, Ibicuí and the Quaraí (Guareim) are short rivers but of considerable volume; the last forms part of the boundary between Brazil and Uruguay. At the mouth of the Quaraí, the Uruguay becomes the boundary line between Argentina and Uruguay, and the river flows almost directly south. The Negro river, 434 mi. (699 km.) long and the Uruguay's largest tributary, joins the latter only 60 mi. from the estuary of the Río de la Plata. The Negro rises on the Brazilian border in Rio Grande do Sul and flows westward through the middle of the Republic of Uruguay. Sizable river craft can reach Mercedes, 32 mi. from its

mouth. Like the Upper Paraná, the Uruguay is generally clear and carries little silt except in the seasonal floods. After its juncture with the Negro, the Uruguay broadens sharply to a width of 4 to 6 mi., and becomes a virtual extension of the Río de la Plata estuary.

Navigation and Economic Importance.—The economic usefulness of these river systems is not commensurate with the area which they drain. A principal problem is that of navigation. A large portion of the rivers cannot be used at all or only by very shallow draught vessels. Elsewhere navigation can only be maintained by constant dredging and renovation of port facilities. The other economic uses to which these rivers might lend themselves, such as irrigation or hydroelectric power, are equally difficult to achieve. The swamps of Xarayes and the Chaco make agriculture a virtual impossibility in these areas, while under present conditions the potential electric power represented by the falls of Guairá or Iguazú is too remote from any centres to be harnessed.

Buenos Aires is one of the principal seaports of the world and the main port of Argentina. Vessels approach it from the main estuary channel by one of two side channels which are clearly marked and dredged to depths of 31 ft. Ocean vessels can travel up the Paraná river as far as Santa Fe or Paraná. The channel depth from the mouth of the Paraná to Rosario is dredged to 21 ft., from Rosario to Paraná to 19 ft. Ocean trade can also reach Concepción del Uruguay directly by the Uruguay river where the dredged depth of the channel is 19 ft.

Commerce farther upstream on these river systems operates under conditions which fluctuate considerably. Passage of vessels depends to a large extent on seasonal variations in depth. A 6-ft. depth is assured from Paraná to Corrientes and usually to Posada, although vessels of deeper draught can often pass. Long fleets of barges carry the bulk of the river freight. The current, narrowness, and curves above Corrientes on the Upper Paraná, however, rule out such barge transport. Several rapids on the Upper Paraná can only be passed with the use of winches to pull the vessels. Narrowness of the river, whirlpools and the increased speed of the current to 5 m.p.h. make navigation more dangerous as the mouth of the Iguazú is approached. The absolute head of navigation is located at Pôrto Mendes below the Guairá falls in Brazil. A railroad, 38 mi. long, circumvents the falls to the town of Guairá, and opens up another 400 mi. of navigable river farther up the Paraná. Beyond, stretches of the Paraná and of tributaries are navigable only by launches or canoes.

On the Paraguay river, vessels drawing 7 ft. and displacing 2,000 tons are able to reach Corumbá in Brazil at all seasons. The most traveled stretch of this river is the 250 mi. from Corrientes to Asunción which is accessible to vessels of 10 ft. draught. Although Corumbá is considered as the head of navigation on the Paraguay, the Bolivian town of Puerto Suárez, 10 mi. away, was built to provide this landlocked nation with a port. Vessels can reach it from Corumbá during the flood season, March to Sept., but its canton population of 3,279 (1962 est.) indicates that it is hardly a major commercial centre.

Some ocean vessels with a draught of 15 ft. can go 25 mi. beyond Concepción del Uruguay on the Uruguay river to Fábrica Colón. A 9 ft. depth is assured as far as Concordia and 6 ft. as far as Salto. Ships of deeper draught reach these river ports in flood time. Above Salto, there are few ports and no measurement of depths is taken. A considerable commerce and movement, however, is carried on by small launches, rafts and canoes.

Navigation of the Pilcomayo, Bermejo and Salado is negligible, because of shifting channels, sandbars and shallowness. Vessels of 3 ft. draught can ascend the Pilcomayo for the first 120 mi. to Fontana, although in a straight line this means only 45 mi. Barges and motorboats on the Bermejo reach Presidencia Rosa, 160 mi. from the mouth, on a regular schedule, although the depth in the shallows is reduced to 2 ft. in the dry season. During high water, November to April, small vessels can ascend the Bermejo 400 mi. from its mouth. Only very shallow draught vessels can use stretches of the Salado.

The value of these river systems as a commercial artery is, therefore, concentrated on the lower reaches. A large volume of

ocean shipping reaches Rosario and Concepción del Uruguay, although the major seaports are Buenos Aires and Montevideo. The great bulk of river transport is concentrated within the limits of Asunción on the Paraguay, Corrientes on the Paraná, and Salto on the Uruguay. The Argentine Flota Fluvial del Estado, the Lloyd Brasileiro and the Compañía Uruguaya de Navegación, however, provide regular passenger and freight service to all navigable parts of these river systems. Rafts, canoes and motorboats provide irregular although important service on the tributaries and upper reaches of these rivers.

A lack of population, remoteness of markets and difficulty of transport are partial reasons for the failure to develop other uses from these river systems. Seasonal rainfall with consequent flooding of large areas may provide a very crude basis for agriculture along the Salado, but it prevents agriculture in vast areas of the Chaco and Mato Grosso. The same remoteness has prevented any effective harnessing of the rivers' power. One exception is the headwaters of the Tieté which, pumped across an intervening range, provide water for a hydroelectric plant near São Paulo.

History.—The Río de la Plata was discovered by Juan Díaz de Solís, chief navigator of Spain, in 1516, as a result of efforts to find a route to the Pacific. The estuary was temporarily named in his memory after his death on its shores at the hands of unfriendly Charrúa Indians. Magellan touched at the estuary in 1520 during his circumnavigation of the globe. In 1526, Sebastian Cabot ascended the rivers as far as the present city of Asunción and obtained silver trinkets in barter with the Guaraní Indians. Spanish dreams gave the estuary its permanent name, Río de la Plata, in the hope that it might indeed become a river of silver. The major Spanish expedition which settled near the present location of Buenos Aires in 1536 under Pedro de Mendoza proved a fiasco. After much misfortune the survivors moved upstream to the surroundings of the more docile Guaraní Indians at Asunción. Buenos Aires was not refounded until 1580, and throughout the Spanish colonial era, the Río de la Plata remained a backwash of the empire. The estuary was virtually closed to legal commerce until the end of the 18th century. Spain only renewed its interest in the area when Portuguese and English ambitions threatened to expand into the Río de la Plata in the 1760s.

Navigation of the river systems became a problem when the national states of Argentina, Uruguay, Paraguay, Brazil and Bolivia emerged on its courses. Territorial conflicts and restrictions on navigation caused several wars, culminating in the titanic struggle by Francisco Solano López's Paraguay against Brazil, Uruguay and Argentina from 1864 to 1870. In the 20th century, similar conflicts sharpened by rumoured oil wealth resulted in the Chaco war between Paraguay and Bolivia.

The development of agricultural wealth, particularly in Argentina, resulted in greater appreciation of the commercial value of these river systems after the mid-19th century. Wheat, beef, wool and hides entered the river and world trade in increasing quantities from Argentina and Uruguay, while from Brazil and Paraguay came forest and tropical products and *yerba mate* or Paraguayan tea. Port construction and dredging made Buenos Aires more valuable as a seaport, and by 1902 similar improvements had been completed at Rosario. Marking of channels, soundings, dredging and other aids to navigation became a responsibility of all the riparian states. See also SOUTH AMERICA; BRAZIL; ARGENTINA; PARAGUAY; URUGUAY. (Js. R. S.)

PLATAEA, an ancient city of Boeotia, Greece, was situated on a triangular ledge 1,000 ft. above sea level, on the north side of Mt. Cithaeron below the modern village of Plataiai; there are remains of ancient walls, and a temple of Hera has been excavated. Strong springs near the city flow into the valley of the Asopus River, which marked the ancient boundary with the territory of Thebes. The city was important in time of war because it was able to threaten the main road from Thebes through Megaris to the Isthmus of Corinth which passed east of Plataea over Mt. Cithaeron.

Plataea was settled by members of the Boeotian tribe who expelled the earlier Bronze Age inhabitants. When a league of Boeotian cities was formed in the 6th century B.C., Thebes pressed

Plataea to join. The Plataeans asked Sparta to protect them, but the Spartan king, Cleomenes I, advised them to go to Athens; the Athenians accepted the task in 519. Despite an attempt by Corinth to arbitrate, the Boeotians attacked some Athenian troops, and Athens then took over Plataea and Hysiae as well. When the Persians landed in Attica (490) the full Plataean levy, numbering about 1,000 men of all arms, came to the aid of Athens and fought on the left wing at Marathon. During the invasion of Xerxes the Plataeans fought at Artemisium (480) and later evacuated their city; in 479 they participated in the Battle of Plataea, which took place below the city (see GRECO-PERSIAN WARS). Thereafter the Plataeans offered sacrifice annually to Zeus the Liberator in honour of the Greek dead, and Plataea was declared inviolable by the Greek states. Nevertheless the Thebans attacked Plataea in 431 and Sparta laid siege to the city in 429, when it upheld its alliance with Athens; two years later the garrison capitulated, the men were executed, and the city was razed. Thebes occupied the site until 387, when Sparta restored the land to the Plataeans who had preserved their identity as Athenian allies with some citizen rights at Athens. The Thebans destroyed Plataea again in 373. Athens harboured the survivors until the Macedonian kings Philip II and Alexander the Great rebuilt their city in the years after 338 as a symbol of Greek courage in resisting Persia. The honour was well deserved. The Plataeans had shown extraordinary loyalty to the Greek cause and their constant ally Athens, and had retained their spirit during two long periods of exile. Thereafter their history was uneventful.

(N. G. L. H.)

PLATEAU INDIANS constituted a major culture of aboriginal North America. The culture area corresponded roughly to the plateau between the Rocky Mountains on the east and the Cascade Mountains (U.S.) and the Coast Range (Canada) on the west. The northern boundary was approximately the great bend of the Fraser River in northern British Columbia (q.v.); the southern limit on the west was near the present California-Oregon boundary and on the east it was the Blue Mountains. The essential cultural uniformity in the Plateau existed despite the geographic contrasts of vast rolling treeless areas, dense forests, and perpetually snow-covered mountains.

Kinship (q.v.) was bilateral throughout the Plateau; polygyny (q.v.) was permitted but rare; such voluntary associations as clubs were absent. However, linguistic differences were great, many mutually unintelligible languages being spoken. The major linguistic stocks (from north to south) with representative tribes were: Athapaskan (q.v.; Sekani, Carrier, Chilcotin); Interior Salish (see SALISHAN; Shuswap, Lillooet, Thompson, Lake, Wenatchi, South Okanagon, Sanpoil, Kalispel, Flathead, Coeur d'Alene, Spokane, Columbia); Sahaptin (q.v.; Kittitas, Yakima, Klikitat, Wanapam, Umatilla, Cayuse, Nez Percé); and Upper Chinook (q.v.; Wishram, Wasco). See also KUTENAI.

Highly diversified tribal economies depended on fish, game, and wild plants. Agriculture was not known, and, except for dogs, there were no domestic animals. The taking of salmon was a prime pursuit except at elevations where waterfalls barred migrating fish. The area is drained primarily by two great systems, the Fraser and the Columbia (world's greatest salmon-producing river). Even tribes on the interior deserts had a regular salmon supply. These and other fish (fresh, or dried for winter) sometimes supplied almost half the tribal subsistence. Deer, elk, and antelope were the principal game; camas, bitterroot, and kause (cous) the main plant foods.

The main dwellings were a semisubterranean lodge used only for winter, and a gabled mat-covered house. The lodge was generally round with a low conical roof of radiating poles covered with mats and earth. The house, a framework of light poles covered with sewn mats of tule or cattail reeds, had a steep roof that sloped to the ground, the ridge being open to release smoke. These light, airy, waterproof and windproof structures were sometimes nearly 100 ft. long. With villages commonly on waterways, dug-

outs and bark canoes were widely used.

Full body dress of finely dressed skins, with supplementary woven or sewed bast fabrics, was characteristic for both sexes. Decoration of beads and embroidery was often elaborate, but facial and body painting was used sparingly.

While the material accomplishments of Plateau Indians were modest, their ideological and political achievements are impressive. Concepts of democracy, equality, and pacifism dominated thought and action. In aboriginal times war was virtually unknown; slavery was rare or absent. Religion was paramount and the unique American Indian guardian spirit concept reached its highest degree of development in this area. Shamans of both sexes were important and respected religious, social, and intellectual leaders (see SHAMANISM).

In what is now the northeastern part of the state of Washington the primary political unit was the village; the tribe was largely an aggregation with a sense of cultural unity that led to recognition of common leadership. Among the Sahaptin a strong tribal system of government put heavy emphasis on chieftainship; chiefly families married intertribally. The Wanapam (Oregon) developed the concept of capital villages and evolved a representative government with a precise hierarchy of village and tribal chiefs. The remarkable Columbia Confederacy (central Washington) embraced the Columbia, Entiat, Wenatchi, and Chelan tribes, with Chief Moses, the most gifted Indian leader of the Northwest, as its notable head. A similar confederation later united the Yakima, Kittitas, Wanapam, Klikitat, and Palouse (Palus) tribes, with Chief Kamaiaikan as their greatest leader. Chief Joseph, leader of the Nez Percé in their war with the U.S., was another noted Plateau chief.

PLATE GLASS: see GLASS MANUFACTURE.

PLATEN-HALLERMÜNDE, AUGUST, GRAF VON (1796–1835), German poet and dramatist who opposed romanticism and in his own work aimed at classical purity of style, was born Oct. 24, 1796, at Ansbach. He entered the Bavarian life guards in 1814, and took part in the campaign in France in 1815. After a tour in Switzerland and the Bavarian Alps, he entered the University of Würzburg in 1818 as a student of philosophy and philology. In 1819 he moved to Erlangen, where he studied under the philosopher of romanticism, F. W. von Schelling, and made the acquaintance of Jean Paul, Jacob Grimm, the oriental scholar and poet Friedrich Rückert, Goethe and Ludwig Uhland. He became a first-rate scholar and as a result of his oriental studies he published a little volume of poems, *Ghaselen* (1821), in which he imitated the style of Rückert. This was followed by *Lyrische Blätter* (1821), *Spiegel der Hafs* (1822), *Vermischte Schriften* (1822) and *Neue Ghaselen* (1823).

Though Platen was at first influenced as a dramatist by the romantics and particularly by Spanish models, the plays he wrote while at Erlangen (*Der gläserne Pantoffel*, *Der Schatz des Rhapsinit*, *Berengar*, *Treue um Treue*, *Der Turm mit sieben Pforten*) show a clearness of plot and expression foreign to the romantic style. His antagonism to romanticism became more pronounced, and he attacked its extravagances, particularly the *Schicksaldrama*, or fate drama, in the witty "Aristophanic" comedies *Die verhängnisvolle Gabel* (1826) and *Der romantische Oedipus* (1829). *Der romantische Oedipus* earned him the enmity of Karl Immermann, whose work was ridiculed in it, and of Heinrich Heine, a close friend of Immermann, but he had many admirers, who delighted in the classical purity of his plays and their polished form and diction. After 1826 he lived in Italy, and his last play, *Die Liga von Cambrai* (1833), and the epic fairy tale *Die Abbasiden* (1834), were written at Naples. He died at Syracuse, Dec. 5, 1835. Platen's odes and sonnets, and his *Polenlieder* (1831) expressing sympathy for the Poles in their rising against the tsar's rule, are among the best classical poems of their time.

Platen's *Gesammelte Werke* were published in one volume in 1839. There is a critical edition in 12 vol. by M. Koch and E. Petzet (1910). His *Tagebücher* (1813-35) were edited by G. von Laubmann and L. von Scheffler, 2 vol. (1896-1900); his correspondence by L. von Scheffler and P. Bornstein, 4 vol. (1911-31).

See R. Schlösser, *August Graf von Platen*, 2 vol. (1910-13); F. Redenbacher, *Platen-Bibliographie* (1926). (A. Gs.)

PLATERESQUE, the earliest of the styles of Spanish Renaissance, so called either because the Renaissance found its first popular Spanish expression in silverware (*platero*, "silver-smith") or because its rich and delicate ornament resembled silver-smith work. It is characterized by the application to structurally simple forms of extremely rich ornament, distantly based on Italian Renaissance forms, using pilasters, entablatures, carved rectangular panels, shallow niches, much heraldic ornament and richly pierced, scrolled cresting. Its courtyards, usually with two or more openings on the upper floor, above a single opening below, are famous for their decorated columns, sometimes simulating balusters, their bracketed capitals and their graceful delicacy. As a result of Moorish influence there is a common tendency to carry the decoration around the door over the full height of the wall above. Decorative ironwork, as in the church *rejeras* or open metal screens, was highly developed. The style embraces, generally, the first half of the 16th century, but its decorative ideals influenced not only the classic period which followed but the baroque as well. Characteristic examples are the hospital of Santa Cruz, Toledo, by Enrique de Egas (1504-16), the college at Alcalá de Henares, the university and Irish college at Salamanca, the Casa de las Conchas at Salamanca and the Infanta at Guadalajara. See RENAISSANCE ARCHITECTURE. (T. F. H.)

PLATE RIVER: see PLATA, RÍO DE LA.

PLATFORM TENNIS is a combination of tennis and squash invented in 1928 by Fessenden Blanchard and James Cogswell at Scarsdale, N.Y. The game is played on specially constructed 60 × 30 ft. wooden platforms. The platform is surrounded by back and side stops of tightly strung wire which are 12 ft. high. The actual court measures 44 × 20 ft. and the net is 2 ft. 10 in. at centre. The paddles or bats, which are used instead of racquets, are oval plywood, metal-bound and perforated, and have short handles. Balls are made of sponge rubber. The rules are the same as tennis with two principal exceptions: balls may be taken off wires, after first striking inside the proper court, and only one serve is allowed.

Since its inception it has gained considerable popularity in the United States. (F. S. Bd.)

PLATINUM is a chemical element which is a very heavy precious silver-white metal. It is the best known and most widely used of the six platinum metals. (See PLATINUM METALS and the articles on individual elements, Iridium, Osmium, Palladium, Rhodium and Ruthenium.) The chemical symbol for platinum is Pt, atomic number 78 and atomic weight 195.09. The usefulness of this metal is due to its resistance to corrosion or chemical attack and to its high melting point of 1,769° C. For example, when brought to a white heat in air, it retains its bright surface. It is scarcely attacked by simple acids but does dissolve readily in aqua regia (HCl:HNO₃). With such a high melting point platinum is not easily fused or cast. In the fabrication of the metal a sponge is commonly made by decomposition of its compounds. The sponge can be hammered and welded at a white heat into massive sheets and various objects. The massive metal has the very high specific gravity of 21.46. However, it is soft and ductile, and thereby unsuited for many purposes. Small amounts of iridium are commonly added to give a harder, stronger alloy which retains the advantages of the platinum. The boiling point of platinum is estimated to be 4,500° C., but the loss of weight of the solid by volatilization above 1,000° C. is very gradual but detectable.

Platinum did not receive general recognition in ancient times. Large deposits as heavy river sands were uncovered in the 16th-century Spanish conquest of South America. The Spaniards called the new metal *Platina del Pinto* after the Río Pinto, from which its present name was taken. Samples of the element re-

ceived the general attention of European scientists in the latter 18th century. Platinum occurs in native alloys which frequently contain smaller amounts of other platinum metals. It is recovered as a by-product in a number of metallurgical operations for the production of copper, nickel, lead and other metals.

Uses.—Platinum and its alloys are indispensable in the chemical laboratory for crucibles and dishes in which materials can be heated to high temperatures. However, some caution must be used, for it is attacked and alloyed by carbon, phosphorus, silicon and some low-melting metals such as lead, arsenic and antimony. It also alloys readily with other platinum metals and with copper, gold and silver. Caustic alkalis at high temperature must be avoided, although alkali carbonates may be fused in platinum ware.

Platinum is used in the preparation of electrical contacts and sparking points because it resists the high temperature and chemical attack of electric arcs. The manufacture of jewelry and dental alloys consumes large amounts of the metal. The prototype international standard metre of length and standard kilogram of mass together with several national copies have been made from the alloy, 90% platinum and 10% iridium. Fine laboratory weights are frequently electroplated with platinum. Platinum electrodes are used in the important electrolytic preparation of hydrogen peroxide, strongly oxidizing salts and acids which corrode other metals. Electrodes of platinum also serve for quantitative electroplating operations in chemical analyses.

The electrical resistance and its temperature coefficient for platinum are relatively high for a metal, and the resistance of coils of exceptionally pure platinum wire therefore gives a precise measure of temperature. The international temperature scale from -190° C. to 660° C. is defined in terms of such a platinum resistance thermometer. At higher temperatures, from 660° C. to 1,063° C. (the melting point of gold), the international temperature scale is defined by the electromotive force of a thermocouple with a wire of pure platinum against another of the alloy, 90% platinum and 10% rhodium. The coefficient of thermal expansion of platinum is low for a metal and near to those of soft glasses, so that thin electrical leads of the metal can be conveniently sealed through glass walls.

Platinum metal surfaces are exceptionally good catalysts for many chemical reactions, especially for reactions which involve the gases hydrogen or oxygen. For this purpose thin deposits of the metal may be formed on an inert supporting material, or fine gauze may be utilized. Also, very finely divided platinum black can be prepared by the reduction of solutions of its compounds or may be deposited by electrolysis on platinum sheet. Large quantities of platinum, which were used to catalyze the oxidation of sulfur dioxide in the manufacture of sulfuric acid, have been mostly replaced by vanadium oxide and other materials; but platinum gauzes serve as catalyst when ammonia is burned in air to yield nitric oxide in the manufacture of nitric acid. Vapours of hydrocarbons or alcohols in air ignite spontaneously, sometimes explosively, on these surfaces. The platinum catalysts can be used in the laboratory for hydrogenation or reduction of organic compounds. The catalytic properties of a platinum-black electrode allows the reversible oxidation of hydrogen gas, and the resultant hydrogen electrode serves as the standard reference electrode for potentials in electrochemistry. Bright platinum wires in ionic solutions function as reversible electrodes for a number of oxidation-reduction systems.

Platinum Compounds.—Platinum forms important series of compounds with the oxidation states of +2 and +4. Many of these compounds contain co-ordination complexes in which chloride, ammonia or other groups are bonded covalently to a central platinum atom. There are bonds from a platinum atom to six groups arranged symmetrically around it toward the corners of an octahedron for the +4 state. For compounds of +2 platinum, four bonds are commonly directed toward the corners of a square, a geometrical arrangement which can occur in chemical systems only under special circumstances of electronic configuration. Complexes of both oxidation states are kinetically inert in that groups are replaced slowly. The preparation of numerous isomers

(complex compounds with the same composition, for example, Peyrone's chloride, *cis*-[Pt(NH₃)₂Cl₂], Reiset's second chloride, *trans*-[Pt(NH₃)₂Cl₂], and Magnus' green salt, [Pt(NH₃)₄][PtCl₄]), provided an important stimulus to the evolution of theories concerning structural arrangements of atoms (stereochemistry). All the compounds of platinum are readily decomposed or reduced to the metal. Many of their aqueous solutions decompose with an appreciable rate below boiling temperature.

When platinum dissolves in aqua regia, hexachloroplatinic (IV) acid, H₂PtCl₆, is formed. The slightly soluble yellow potassium and ammonium hexachloroplatinate (IV) are readily precipitated and are useful in analysis. Pure sponge metal is usually prepared by ignition of (NH₄)₂PtCl₆. Heated with sodium hydroxide, hexachloroplatinic (IV) acid gives soluble Na₂Pt(OH)₆ which yields yellow hydrous hydroxide when neutralized with weak acid. The hydroxide can be dehydrated to give black PtO₂. Electrolysis of the alkaline solutions gives a hydrous oxide corresponding to a higher oxidation state. Hydrates of hexachloroplatinic (IV) acid can be crystallized; and if the crystals are heated to 300° C. in an atmosphere of chlorine, a reddish-brown PtCl₄ is formed.

PtCl₄, heated to above 360° C., yields a green-brown platinum (II) chloride, PtCl₂, which is insoluble in water but dissolves very slowly in HCl solution to give the red solution of tetrachloroplatinic (II) acid, H₂PtCl₄. This acid is readily prepared by the reduction of H₂PtCl₆ with sulfur dioxide. When alkali is added to a solution of a tetrachloroplatinate (II), a hydrous black platinum (II) hydroxide is precipitated. It can be dehydrated to gray PtO with some decomposition to metal. Hydrogen sulfide precipitates a black sulfide, PtS.

See also references under "Platinum" in the Index.

(D. S. MN.)

PLATINUM METALS are a group of six chemical elements, including platinum, which are generally found together in nature with varying proportions in the metallic form. The elements are listed in the accompanying table together with their important atomic and physical properties. (See also IRIDIUM; OSMIUM; PALLADIUM; PLATINUM; RHODIUM; RUTHENIUM.)

The group is naturally divided into light and heavy triads of three elements each. For each light element there is a heavy element whose atomic number is greater by 32. The two elements in each such pair belong to the same family of the periodic table of elements so that three families are represented. As is normally the case, elements of the same family have strikingly similar chemical and physical properties. Although some similarities are noted among the entire group, there are wide differences in the chemical behaviour between different families. The six platinum metals are included together with iron, cobalt and nickel as Group VIII of the periodic table of elements.

Each of the individual elements is a silver-white metal. Although none melt below a white heat, there is still a wide range in the melting points. With such high melting points they are difficult to fuse or cast. Their boiling points can only be estimated roughly from extrapolations of vapour pressure measurements. The specific gravities of the light triad fall in the narrow range of 12.0–12.5; the heavy triad are exceptionally dense.

Osmium and iridium, whose densities are equal within the experimental accuracy; are the densest terrestrial materials known. Platinum and palladium are soft, ductile and easily worked; the other members are hard and difficult to work in the cold. However iridium and rhodium can be worked at a white heat. An important common property of the group is the instability of their chemical compounds which are readily decomposed or reduced to yield the free

elements in the form of a metal sponge or powder. Chemists accordingly classify all members of the group as noble metals.

History and Occurrence.—None of the platinum metals received widespread recognition in ancient times, although artifacts containing platinum have been uncovered occasionally by archaeologists. Large deposits of platinum were first recognized in South America during the 16th-century Spanish conquest. The Spanish government originally held a low regard for the metal because its high density permitted the preparation of counterfeits for gold which were difficult to detect. The new metal came to the general attention of European scientists in the late 18th century. Within the two-year period 1803–04 the discoveries of four new elements from crude platinum were announced in England—palladium and rhodium by William H. Wollaston and osmium and iridium by Smithson Tennant. Although other elements were thought to be contained in crude platinum at times, Carl Claus in Russia demonstrated the existence of the remaining rare metal of the platinum group in 1844. He chose for it the name ruthenium, which G. W. Osann had suggested earlier.

Since compounds of all the platinum elements are readily decomposed to give dense metals, it is not surprising that the six elements have been concentrated together as native alloys by geological processes. The earliest deposits to be worked were heavy river sands which had been concentrated by gravity. Primary deposits of the metals dispersed in basic and ultrabasic igneous rocks have since been productive. They are normally accompanied by other elements such as gold, and compounds of iron and nickel. Platinum metals are sometimes included in sulfide deposits and are recovered as by-products in the metallurgical operations for copper, nickel and other metals. The earliest workings of platinum were in Colombia and Brazil. In 1819 platinum was discovered in the Ural mountains, and since about 1825 Russia has been a dominant producer of the metals. For a period, 1828–41, coins were minted from a platinum-iridium alloy in Russia. Limited occurrences have been found in many areas of the world. Ores from the Republic of South Africa and the nickel ores of the Sudbury, Ont., area have given especially high continued yields. Because sources of the elements are limited, the metals command high prices which have fluctuated widely.

In atomic energy reactors isotopes of the light triad are formed together with more than 30 other elements as products of the nuclear fission of uranium, plutonium or thorium. It is necessary to effect their removal from the fissionable materials and sometimes from other fission products under difficult conditions imposed by the radiation hazards for large-scale applications of atomic energy.

Uses.—Platinum is the most readily available and widely used of the metals in the group. Its utility depends mostly upon its high melting point and its resistance to chemical attack by the atmosphere and by many chemical agents. The metals are used in the electrical industry for resistors, contacts and sparking points. In the chemical industry and laboratory they are used for dishes, crucibles, electrodes, nozzles and other objects which must resist

^aPossibly radioactive.

corrosion. Also large quantities are consumed for dental alloys and decorative purposes in jewelry. The surfaces of these metals are extremely active catalysts for a number of chemical reactions. Therefore they are widely used in the laboratory and in industry to accelerate chemical reactions despite their high cost. However, unless wastage is very small, cheaper materials, which may be less effective catalysts, are frequently used.

Chemical Properties.—Platinum can be heated to a white heat in air without losing its bright surface. It is not attacked by simple acids but does dissolve readily in aqua regia. None of the metals in the massive form is appreciably oxidized by the atmosphere at room temperature. However, when heated in air osmium is converted to the tetroxide, OsO_4 , a volatile poisonous compound (boiling point 131°C.) with an unpleasant odour; and ruthenium oxidizes to give RuO_2 . The other elements oxidize only superficially in the air. Palladium slowly dissolves in concentrated nitric or sulfuric acid, and osmium forms OsO_4 with fuming nitric acid. Even aqua regia scarcely attacks ruthenium, rhodium or iridium. A fused mixture of sodium hydroxide and sodium nitrate is an effective agent which will oxidize all of the elements.

A few examples suffice to show the wide differences in chemical properties among the group. Osmium and ruthenium are alone among all known elements in forming a few well-characterized compounds with the +8 oxidation state, for example RuO_4 , OsO_4 , OsF_8 and KOsO_3N . The volatility of the tetroxides permits convenient, efficient and rapid separation of these two elements.

All the platinum metals can form compounds with more than one oxidation state. For ruthenium there is evidence for compounds in every oxidation state from +1 through +8. However, both ruthenium and osmium are normally encountered in the states +3, +4, +6 or +8. In contrast, rhodium is limited with a few exceptions to the +3 oxidation state, whereas iridium forms important compounds for the +3 and +4 states. Palladium and platinum compounds are largely confined to the +2 and +4 states, the latter being very unstable for palladium.

All the platinum elements are characterized by a tendency to form co-ordination complexes in which chloride, ammonia, water or other groups are bonded covalently to the central metal ion. Replacements of one group by another, especially in the complexes of the heavy triad, are frequently slow.

Separation.—Processes for the recovery of the metals from the ores remain somewhat as trade secrets of individual firms and depend partly upon the composition and nature of metallurgical concentrates which must be handled. Commonly, at one step a mixture of the metals is dissolved in aqua regia. However, the mineral osmiridium, an alloy rich in osmium and iridium, is not dissolved by aqua regia. If it is heated with zinc it yields an alloy which is acid-soluble. The osmium distills away from the aqua regia solution as OsO_4 upon boiling. NH_4Cl added to an HCl solution of the remaining elements precipitates $(\text{NH}_4)_2\text{PtCl}_6$ and $(\text{NH}_4)_2\text{IrCl}_6$. These two compounds can be separated by repeated fractional crystallizations of the less soluble platinum compound. After platinum and iridium are removed, a precipitate of $[\text{Pd}(\text{NH}_3)_2\text{Cl}_2]$ can be formed by the addition of aqueous ammonia followed by HCl . If the remaining material in solution is reduced to metal and treated with fused potassium hydrogen sulfate, the rhodium is recovered as a soluble complex sulfate, $\text{K}_3\text{Rh}(\text{SO}_4)_3$. A ruthenium concentrate which remains can best be dissolved by a potassium hydroxide-potassium nitrate fusion and purified by a distillation procedure. (D. S. MN.)

PLATO (428/427–348/347 B.C.), Greek philosopher whose influence on thought has been continuous for more than 2,400 years, was the son of Ariston and Perictione. His family was, on both sides, one of the most distinguished of Athens. Ariston is said to have traced his descent through Codrus to the god Poseidon; on the mother's side, the family, that was related to Solon, goes back to Dropides, archon of the year 644 B.C. Perictione apparently married as her second husband her uncle Pyrilampes (*Parmenides* 126 b) a prominent supporter of Pericles, and Plato was probably chiefly brought up in his house: Critias and Charmides, leading men among the extremists of the oligarchic terror of 404, were re-

spectively cousin and brother of Perictione; both were old friends of Socrates, and through them Plato must have known the philosopher from boyhood.

His own early ambitions as he tells us in the *Epistle* vii, 324 b–326 b, were political. The reactionaries urged him to enter public life under their auspices—at the age of 24—but he wisely held back until their policy should declare itself. He was soon repelled by their violences, particularly by their attempt to implicate Socrates in the illegal execution of their victim Leon. He hoped better things from the restored democracy, but its condemnation of Socrates finally convinced him that there was no place for a man of conscience in active politics. Hermodorus, an immediate disciple, is the authority for the statement that, on the execution of Socrates in 399 B.C., Plato and other Socratic men

took temporary refuge with Euclid at Megara. The later biographies represent the next few years as spent in extensive travels in Greece, in Egypt and in Italy. Plato's own statement is only that he visited Italy and Sicily at the age of 40 and was disgusted by the gross sensuality of life there, but found a kindred spirit in Dion, brother-in-law of Dionysius I of Syracuse.

The Academy and Sicily.

About or soon after 387, Plato founded the Academy as an institute for the systematic pursuit of philosophical and scientific research. He presided over it for the rest of his life, making it the recognized authority alike in mathematics and in jurisprudence. From the allusions of

PLATO: ANCIENT GREEK CARVING, CONSIDERED AN AUTHENTIC PORTRAIT. IN THE STAATLICHE MUSEEN, BERLIN

Aristotle we gather that Plato lectured without manuscript, and we know that "problems" were propounded for solution by the joint researches of students. On the political side there are traces of tension between the Academy and the rival school of Isocrates.

The one outstanding event in Plato's later life is his intervention in Syracusan politics. On the death of Dionysius I in 367, Dion conceived the idea of bringing Plato to Syracuse as tutor to his successor, whose education had been neglected. Plato himself was not sanguine of results, but as both Dion and the philosopher-statesman Archytas of Tarentum thought the prospect promising, he felt bound in honour to risk the adventure. The project was by training Dionysius II in severe science to fit him for the position of a constitutional king who might hold Carthaginian encroachment in Sicily at bay. The scheme was crushed by his natural jealousy of the stronger Dion, whom he drove into virtual banishment. Plato paid a second and longer visit to Syracuse in 361–360, in the hope of still effecting an accommodation, but failed, not without some personal danger. When Dion captured Syracuse by a *coup de main* in 357, Plato wrote him a short letter of congratulation and warning against his own lack of tact and graciousness. After the murder of Dion in 354 the philosopher drew up his important *Epistles* vii and viii, reviewing and justifying the policy of Dion and himself and making proposals, unsuccessfully, for a conciliation of Sicilian parties.

The prejudice which led students in the 19th century to discredit the *Epistles*, in spite of the favourable opinion of scholars such as Richard Bentley, C. G. Cobet, George Grote, F. Blass and E. Meyer, worked havoc with their accounts of Plato's life. It is safe to say that the two letters of chief biographical importance, vii and viii, have the best claim to authenticity, i and xii the weakest.

To us Plato naturally is important primarily as one of the greatest of philosophical writers, but to himself the foundation and organization of the Academy must have appeared his chief work. In *Epistle* vii, 341 b–e, 344 c, he utters on his own account the

same comparatively unfavourable verdict on written works, in contrast with the contact of living minds, as a vehicle of "philosophy," which he ascribes to Socrates in the *Phaedrus*. It can hardly be doubted that he regarded his dialogues as intended in the main to interest an educated outside world in the more serious and arduous labours of his "school."

All the most important mathematical work of the 4th century was done by friends or pupils of Plato. Theaetetus, the founder of solid geometry, was a member of the Academy, as were also the first students of the conic sections. Eudoxus of Cnidus, author of the doctrine of proportion expounded in Euclid's *Elements*, inventor of the method of finding the areas and volumes of curvilinear figures by exhaustion and propounder of the astronomical scheme of concentric spheres adopted and altered by Aristotle, removed his school from Cyzicus to Athens for the purpose of co-operation with Plato. Archytas, the inventor of mechanical science, was a friend and correspondent. The Academy is thus the link between the mathematics of the 5th-century Pythagoreans and those of the geometers and arithmeticians of Alexandria.

Nor were other sciences neglected. Speusippus, Plato's nephew and successor, was a voluminous writer on natural history; Aristotle's biological works have been shown to belong largely to the early period in his career immediately after Plato's death, before the breach between the younger philosopher and the Academy. The comic poets found matter for mirth in the attention of the school to botanical classification. The Academy was particularly active in jurisprudence and practical legislation. "Plato sent Aristonymus to the Arcadians, Phormion to Elis, Menedemus to Pyrrha. Eudoxus and Aristotle wrote laws for Cnidus and Stageirus. Alexander asked Xenocrates for advice about kingship; the man who was sent to Alexander by the Asiatic Greeks and did most to incite him to his war on the barbarians was Delius of Ephesus, an associate of Plato." (Plutarch, *Adversus Coloten*, 1126 c-d). The creation of the Academy as a permanent society for the prosecution of both exact and humane sciences was, in fact, the first establishment of a university. (See ACADEMY, GREEK.)

Formative Influences.—The most important formative influence to which the young Plato's mind was exposed was that of Socrates. But it does not appear that Plato, whose first ambitions were political, belonged to the innermost circle of the old man's intimates, or regarded himself as a "disciple." In *Epistle vii* he is careful to speak of Socrates not as a "master" but as an older "friend" (*hetairoi*) for whose character he had a profound respect; and he has recorded his own absence (through indisposition) from the death scene of the *Phaedo*. It would seem that his own vocation to philosophy dawned on him only afterward, as he reflected on the moral to be learned from the treatment of Socrates by the democratic leaders. Aristotle incidentally ascribes to him an early familiarity with the Heraclitean Cratylus, a younger man than Socrates and apparently an admirer of the philosopher. This may be only Aristotle's inference from the existence of the dialogue *Cratylus*. It is more important to remember Plato's connection with Pyrilampes and Critias. Pyrilampes was a Periclean politician, and Critias was known as a democrat until his moral balance was upset by the collapse of the Periclean system in 404. Early upbringing in a family of Periclean politics having connection with Solon may explain why Plato's own estimate of democracy in the *Politicus* and *Laws* is much less unfavourable than that which he ascribes to Socrates in the *Gorgias* and *Republic*.

Beyond this, we can say only that Plato in early life must have been exposed to the same influences as his contemporaries. His early experiences covered the disastrous years of the Deceliean War, the shattering of the Athenian empire and the fierce civil strife of oligarchs and democrats in the year of anarchy 404–403. He was too young to have known anything by experience of the imperial democracy of Pericles and Cleon, or of the tide of the sophistic movement. It is not from memory that he depicts Protagoras, or even Alcibiades, as they were in their great days.

THE DIALOGUES

The fixing of the canon and text of Plato has often been attributed to two scholars, Dercylides and Thrasyllus, either shortly

before or shortly after the Christian era (but see ACADEMY, GREEK). Thrasyllus is uncertainly identified with Thrasyllus of Mende and generally assumed to have been astrologer to and friend of Tiberius. By reckoning the *Epistles* as one item, the list was made to consist of 36 works, arranged in nine tetralogies, or groups of four. (Aristophanes of Byzantium had already attempted an arrangement in trilogies, or groups of three, which, however, he did not carry through.)

No genuine work of Plato has been lost, but there is a general agreement of modern scholars to reject a number of small items from the text. Their verdict may be said to have gone definitely against the following: *Alcibiades I*, *Alcibiades II* (suspected by some even in ancient times), *Theages*, *Erastae*, *Clitophon*, *Hipparchus*, *Minos*. Most or all of these are probably early Academic work, and possibly not all later in date than Plato's death. Most, though not all, contemporary scholars also regard the *Epinomis*—in the present writer's opinion wrongly—as an appendix to the *Laws* added *de suo* by the mathematician Philippus of Opus, who is recorded by Diogenes Laërtius (iii, 37) to have transcribed the work for circulation. The *Hippias Major* and the *Menexenus* are still regarded as doubtful by some, though Aristotle used both in a way which seems to prove that he regarded them as Platonic (he expressly quotes the *Menexenus*). Plato's will, preserved by the same Diogenes (iii, 41–43), is pretty certainly authentic. Some of the 32 epigrams ascribed to him in the *Anthology* may conceivably be genuine.

Order of Composition.—Plato's literary career extended over the greater part of a long life. The *Apology* must have been written while the memory of Socrates' appearance before his judges was still fresh; the *Laws* is confessedly the work of an old man with a long experience of life behind him, and the state of its text fully bears out the tradition, preserved by Proclus, that its aged author never lived to give it final revision. Half a century or more must have elapsed between Plato's last and his earliest composition.

This of itself would prove that F. Schleiermacher, with whom modern critical study of Plato begins, went astray in assuming that Plato started his career with a ready-made complete "system" to be disclosed. We must expect to find in his writings evidence of the development of his mind. But if we are to read the development aright we must have some trustworthy way of determining the order of the dialogues. Plato himself has given us only the scantiest indications of the order. He has linked the *Sophistes* and the *Politicus* externally with the *Theaetetus* as continuations of the conversation reported in that dialogue; he has also, as most students recognize, linked up the *Timaeus* in the same way with the *Republic*. Aristotle adds one other piece of information, that the *Laws* were written after the *Republic*.

Further investigation of the problem opens in 1867 with L. Campbell's edition of the *Sophistes* and the *Politicus*, and the work thus begun was continued by others, notably W. Dittenberger, M. Schanz, C. Ritter, H. Arnim and W. Lutoslawski.

By consideration of independent stylistic criteria, it has been definitely established that the dialogues *Sophistes*, *Politicus*, *Philebus*, *Timaeus* (with its fragmentary sequel *Critias*) and *Laws* form a distinct linguistic group, which must belong to the later years of Plato's life, as we might have presumed from the consideration that Socrates, the central figure of other dialogues, becomes, in those of this group (with a solitary exception for the *Philebus*, the one member of the group which is wholly preoccupied with ethics), a secondary personage and disappears altogether from the *Laws*. The whole group must therefore be later than the *Sophistes*, which professes to be a sequel to the *Theaetetus*. Now the *Theaetetus* can be dated with some accuracy, since it commemorates the recent death of the eminent mathematician after whom it is named from disease and injury contracted in a campaign before Corinth, which, as elaborately proved by Eva Sachs (*De Theaeteto Atheniensi*, 1914), must be that of 369 B.C. The dialogue may thus be safely ascribed to 368–367, the eve of Plato's departure for Syracuse, and the marked change of style visible in the *Sophistes* is best explained by the supposition that there was a break in Plato's literary activity during the years 367–360 when he was

specially occupied with Sicilian affairs. So much may be regarded as fairly certain.

It is not so easy to reach conclusions about the order of composition of the earlier group of dialogues. It is generally recognized, on linguistic and other grounds, that the series ends with the *Theaetetus* and the closely related *Parmenides*. Ritter, Lutoslawski and others tried to determine the internal order of the group on linguistic evidence, but there are obvious reasons for doubting whether the methods which proved successful in establishing the distinction between the two great groups of earlier and of later dialogues can be applied with the same confidence to works belonging to the same general period of their author's life and composed probably at no great distance of time from one another.

In point of fact, there is no complete agreement between the arrangements proposed by different "stylometrists," and their advocates have usually eked out the strictly philological argument by more or less dubious assumptions about the development of Plato's thought, though it is very questionable whether any real development can be traced before the *Theaetetus* and the *Parmenides*. Perhaps all that can be said with certainty is that the great outstanding dialogues, *Symposium*, *Phaedo*, *Republic* (and perhaps also *Protagoras*), in which Plato's dramatic power is at its highest, mark the culmination of this first period of literary activity. The comparative decline of dramatic power, accompanied by compensating maturity of critical acumen, is the most striking contrast between the dialogues of the second and those of the first period. A good account of the work done by the "stylometrists" is to be found in H. Raeder, *Platons philosophische Entwicklung* (1905), another in an article by C. Ritter in *Bursians Jahresbericht*, vol. 187, i (1921).

The Persons of the Dialogues.—The great initial difficulty which besets the modern student of Platonic philosophy is that created by the dramatic form of Plato's writings. Since Plato never introduces himself into his own dialogues, he is not formally committed to anything which is taught in them. The speakers who are formally bound by the utterances of the dialogues are their protagonists, Socrates, Parmenides, the Pythagorean Timaeus, and all these are real historical persons. The question thus arises, with what right do we assume that Plato means us to accept as his own the doctrines put into the mouths of these characters? Is his purpose dogmatic and didactic, or may it be that it is mainly dramatic? Are we more at liberty to hold Plato responsible for what is said by his dramatis personae than we should be to treat a poet like Browning in the same fashion?

It is tempting to evade this formidable issue in one of two ways. One is that of Grote, who held that Plato allows himself freely to develop in a dialogue any view which interests him for the moment, without pledging himself to its truth or considering its compatibility with other positions assumed elsewhere in his writings. Thus, according to this theory, Plato can make Socrates tolerate hedonistic utilitarianism in the *Protagoras* and denounce it in the *Gorgias*, or can assert the so-called ideal theory through the mouth of Socrates in the *Phaedo* and refute it in the character of Parmenides in the dialogue of that name, with equal gusto and without pledging himself to any view. His championships are purely dramatic, or, at most, reflect his passing mood at the moment of composition.

The more common assumption of the 19th century was that some of Plato's characters, notably Socrates and Timaeus, are "mouthpieces" through whom he inculcates tenets of his own, without concern for dramatic or historical propriety. Thus it was and often still is held that the most famous philosophical doctrines of the *Phaedo* and *Republic*, the "ideal theory," the doctrine of "recollection" and of the tripartite soul, were actually originated by Plato after the death of Socrates (to whom these speculations were supposed to be entirely unknown) and consciously fathered on the older philosopher by a mystification too glaring to deceive any one seriously. Careful study of the dialogues should satisfy us that neither of these two extreme views is tenable.

The Thought of the Earlier and Later Dialogues.—There is undeniably a real difference between the thought of the dialogues

which are later than the *Theaetetus* and those which are earlier, and this difference will have to be accounted for. But there are no serious discrepancies of doctrine between the individual dialogues of the same period.

Now Plato seems to announce his own personal conviction of certain doctrines of the second group of dialogues by a striking dramatic device. In the *Sophistes* and *Politicus* the leading part is taken by an Eleatic and in the *Laws* by an Athenian who are the only anonymous, indeed almost certainly the only imaginary, personages in the whole of Plato's writings (except the two minor personages of the *Laws*, a Spartan and a Cretan, who have really nothing to do except to say "Yes," "No," in the appropriate places). It can hardly be doubted that the reason why these two characters have been left anonymous is precisely that the writer may be free to use them as "mouthpieces" for his own teaching. Plato thus takes on himself the responsibility for the logic and epistemology of the *Sophistes* and of the *Politicus* and for the ethics and educational and political theory of the *Politicus* and of the *Laws* in a specially marked way, and by doing so compels us to face the question how far he means the utterances of Socrates in his earlier dialogues to be taken as expressions of a philosophy of his own.

Forms.—It may be regarded as an established result of the inquiries of Henry Jackson and others that there is a definite philosophical doctrine running through the earlier dialogues which has as its main features the theory of "Forms" (the ideal theory; see FORM), the theory that knowledge is "recollection" and the theory of the "tripartite soul." In the dialogues of the second period these tenets, as we have learned to know them from the earlier dialogues, appear only in the mouth of Timaeus, a 5th-century Pythagorean older than Socrates; and the most important of them all, the theory of "Forms" is actually made the object of what looks like a refutation in the *Parmenides*.

The problem is to find an explanation of this puzzling fact. Are we to distinguish two philosophies, both originated by Plato after the death of Socrates, an earlier and a later? Or are we to suppose that in the main the object of the first group of Plato's dialogues is to preserve the memory of Socrates and that the philosophy expounded is in the main what it professes to be, the thought of Socrates, coloured, no doubt, unconsciously but not consciously distorted, in its passage through the mind of Plato? On the second view we should have to say that, strictly speaking, Plato had no distinctive Platonic philosophy until a late period in his life, much as we can say that, though Kant was all through his life a prolific writer on philosophy, there was no distinctive Kantian philosophy before the *Critique of Pure Reason*. Most Platonic scholars are still unwilling to accept this interpretation of the facts, though there are weighty considerations which plead strongly for it.

Socrates and Plato.—It is significant that the only dialogue not earlier than the *Theaetetus* in which Socrates takes a leading part is the *Philebus*, the one member of the second group which deals exclusively with those ethical problems on which the thought of the historical Socrates had been specially concentrated. This is most naturally explained by supposing that Plato, from regard to fact, was unwilling to make Socrates the exponent of doctrines which he knew to be his own property, though it is hard to understand his misgivings if he had already for years been employing him in that very capacity. (If, as is most probable, *Epistle ii* is authentic, the question would be definitely settled by the sentence of the latter [314 c] "there is not, and never will be, a work of Plato; the works which now go by that name belong to Socrates embellished and rejuvenated.")

It is notable, too, that Aristotle apparently knew nothing of an earlier and a later version of Platonism. He attributes a definite doctrine to Plato which is quite unlike anything to be found in the first great group of dialogues, and seems to be known to him from oral communications in the Academy, though something similar to it can, by looking hard, be read between the lines in the *Philebus*. It was also the view of Neoplatonic scholars such as Proclus that the ideal theory expounded in the great earlier dialogues really originated with Socrates and that something of the same kind

was also held by contemporary Pythagoreans in Italy (Proclus, *Commentarii in Parmenidem*, edited by G. Stallbaum [1839], 562, 610), and the fact that Proclus does not find it necessary to argue the point seems to show that this had been the standing tradition of the Academy. Similarly Galen, early in the 3rd century A.D., cites the definite statement of the learned Stoic Poseidonius that the doctrine of the "tripartite soul," often said in modern times to be another invention of Plato's, is as old as Pythagoras (*De Placitis Hippocratis et Platonis*, 425, 478).

Moreover, as J. Burnet argued, it is hard to believe that any writer would introduce a far-reaching novel speculation of his own to the world in the curious fashion which Plato is supposed to have adopted in the *Phaedo*, where Socrates is made to describe the ideal theory as something quite familiar which he has for years constantly canvassed with his intimates (nearly all, if not all, of whom, were certainly living when the *Phaedo* was circulated). It is not necessary here to determine the historical question. We may be content to turn to the Platonic dialogues, carefully distinguishing the successors of the *Theaetetus* from its predecessors, and attempt a summary of their contents. The general doctrine of the first period will be described without any more or less arbitrary attempt to say how much of it may be actually Socratic. We may then consider how far this doctrine is modified in later dialogues, or in the version of Platonism presupposed by Aristotle's criticisms.

No attempt will be made here to describe the personality or temperament of Plato which is, in fact, as elusive as that of Shakespeare and for the same reason. He is often credited with a strongly "mystical" and "erotic" temperament. He does ascribe such a temperament to Socrates, but it is puerile to treat his picture of Socrates as evidence about himself, though the mistake is constantly committed.

It should therefore be noted that the "mysticism" is confined to dialogues of the first period, in which Socrates is its exponent, and that the "erotic" language in which Plato's Socrates speaks of his devotion to his young friends was also used by the Socrates of Aeschines to describe his relations with Alcibiades (fragment 4, edited by H. Krauss, 1911). There is no evidence that Plato personally ever fired the imagination of gifted boys as Socrates did. Apart from the *Epistles*, the most valuable light we possess on Plato's personality is afforded by Aristotle's description of him as a man "whom it is blasphemy in the base even to praise."

THE EARLIER DIALOGUES

In the *Republic*, the greatest of all the dialogues which precede the *Theaetetus*, there may be said to be three main strands of argument deftly combined into a consummate artistic whole, the ethical and political, the aesthetic and mystical and the metaphysical. Other major dialogues belonging to this period give special prominence to some one of these three lines of thought; the *Phaedo* to the metaphysical theme, the *Protagoras* and the *Gorgias* to the ethical and political, the *Symposium* and the *Phaedrus* to the aesthetic and mystical, though in none does Plato make an artificially rigid separation of any one of the great ideal interests of human life from the rest.

The shorter dialogues deal with more special problems, usually of an ethical character, and mostly conform to a common type. A problem in moral science, often that of the right definition of a virtue, is propounded, a number of tentative solutions are considered and are all found to be vitiated by difficulties which we cannot dispel; we are thus left, at the end of the conversation, aware of our discreditable ignorance of the very things it is most imperative for man to know. We have formally learned nothing but have been made alive to the worthlessness of what we had hitherto been content to take for knowledge and the need of seeking further enlightenment.

The effect of these dialogues of search is thus to put us in tune with the spirit of Socrates, who had said that the one respect in which he was wiser than other men was just his keen appreciation of his own ignorance of the most important matters. We learn the meaning of his ruling principle that the supreme business of life is to "tend" the soul (to make it as good as possible) and his

conviction that "goodness of soul" means first and foremost, knowledge of good and evil. The three dialogues directly concerned with the trial of Socrates have manifestly a further purpose. They are intended to explain to a puzzled public why Socrates thought it stuff of the conscience neither to withdraw from danger before trial, nor to make a conciliatory defense, nor, finally, to avail himself of the opportunity of flight after conviction. Even well-wishers such as Xenophon, as we know, were puzzled by what had seemed his wilfully defiant attitude; it was therefore a debt of honour to his memory to put the matter in the true light. In the remarks which follow, we will consider these shorter dialogues in an order adopted simply for purposes of convenience.

Hippias I and II.—In these dialogues Socrates has as respondent the well-known polymath Hippias of Elis, whose self-complacency is sharply satirized. In the *Hippias Major* the question propounded is "What is the fine" (*kalon*)? "Fine" is a predicate by which we are constantly expressing both aesthetic and moral approval; do we really know what we mean by it? We discover that we do not, though incidentally we also learn that "fine" or "beautiful" is certainly not a synonym for either "useful" or "pleasant." *Hippias Minor* deals directly with the famous Socratic paradox that "wrong-doing is involuntary." It is commonly held that it is much worse to tell a wilful untruth than to blunder into an unintentional false statement. Yet the analogy of the arts and professions seems to show that the man who errs intentionally, if there is such a person, is a better man than he who errs unintentionally. (The suggested thought, of course, is that there is no such person. The man who knows what is good will always aim at this and at nothing else,—the familiar doctrine of Socrates.)

Ion, Menexenus.—Both these are occasional works. Socrates had said that he found the poets, who as a class are commonly reckoned "wise," quite unable to explain to him how they came to say their best things, or what they meant by them. (*Apology* 22 a-c.) The *Ion* develops this thought into the theory that neither the poet, nor his interpreter the rhapsode, produces his effects "by science," that is, as a result of conscious artistry; the effect in both cases is due to a nonrational inspiration, or, as we now say, native genius. (The importance of this is that it rules out appeal to the poets as specially competent authorities on the conduct of life.)

The *Menexenus*, which professes to repeat a funeral oration learned from the famous Aspasia, is apparently meant as a satire on patriotic distortion of history. Apparently the discourses satirized are those of Pericles in Thucydides, Lysias (*Oratio* ii) and Isocrates (the *Panegyricus*). The singular anachronism by which Socrates (and Aspasia) are represented as commenting on the events of the Corinthian War down to the year 387 must be intentional, whatever its object.

Charmides, Laches, Lysis.—These are typical dialogues of search. The question of the *Charmides*, which contains a particularly delightful picture of the way of Socrates with a promising lad, is what is meant by *sophrosyne*, the virtue which is shown alike in graceful and easy command of one's appetites and passions, in dutiful behaviour to parents, elders, official "superiors," in balance and sanity amid the ups and downs of fortune. We seem to be in a fair way to identify this virtue with "knowledge of self"—the self-knowledge Socrates had valued so highly—when we are confronted with an ambiguity. Self-knowledge might be taken to mean a knowledge which has knowledge itself for its object, in fact for epistemology. But it is hard to be sure that there is any such science as the knowledge of knowledge and harder still to see how such knowledge could be directive of conduct.

In the *Laches* we are concerned with valour, the soldier's virtue. Here again we are on the point of defining the virtue as knowledge of what is and what is not really to be dreaded. But this is tantamount to saying the true knowledge of evil and good, and the resultant definition "valour is knowledge of good," would identify valour with the whole goodness of man. That is, the definition is only possible if we can meet the popular objections to the Socratic thesis of the unity of virtue.

The *Lysis* examines in the same tentative way, friendship, the relation in which self-forgetting devotion most conspicuously displays itself. The crux of the problem is that after many false starts, we seem to have reached a promising result in the view that each friend is really "a part of" the other in "soul or temper or body," and yet it is hard to reconcile this position with the facts which seem to show that "unlikeness" is a potent source of attraction. Aristotle has taken up and discussed the issues raised in the dialogue in his own treatment of the same subject (*Nicomachean Ethics*, viii-ix).

Cratylus.—The question here, one much agitated in the age of Socrates, is whether names are significant by nature or convention. Is there some special appropriateness of the sounds of names to the objects called by them, or is there no bond between the thing and its name but that of the "usage of the community"? The absurdity of attempts to get metaphysics out of etymologies is humorously exposed by showing that the method can be used at pleasure to prove either that the "giver of names" agreed with Heraclitus that motion is the sole reality or that he held, with Parmenides, that motion is an illusion. Yet there are real analogies between "vocal gestures" and the things signified by them, which are pointed out with a good deal of insight. The main purpose of Plato, however, is to dwell on the point that language is an instrument of thought; the test of its rightness is not mere social usage, but its capacity to express true thought accurately.

Euthydemus.—The dialogue is, in large part, broad satire on "eristics" who misapply the logic of Zeno for the purpose of entangling anyone who commits himself to any assertion in fallacies because of the ambiguity of language. (Aristotle has drawn freely upon it in his essay on fallacies, the *De Sophisticis Elenchis*.) Its more serious purpose is to contrast this futile contradiction mongering with the "protreptic" of Socrates. The lad Clinias is simply bewildered by the questions of the two professors of "eristic"; those of Socrates have the purpose of convincing him that the happiness we all desire is not guaranteed by the possession of the things the world accounts good, but depends on our making the right use of them. If we would attain happiness we must "tend" our "souls," and that means that we must acquire the "royal" science which ensures that we shall make the right use of all the gifts of mind, body and fortune, in other words, the knowledge of true and absolute good.

Gorgias.—The *Gorgias* is a greater as well as a much longer work than any of those hitherto considered. Beginning ostensibly as an inquiry into the nature and worth of rhetoric, the art of advocacy professed by Gorgias, it develops into a plea of sustained eloquence and logical power for absolute right, as against expediency, as the sovereign rule of life private and public, and ends with an imaginative picture, on Orphic lines, of the eternal destinies of the righteous and of the unrighteous soul. Literature has no more impressive presentation of the claim of conscience to unqualified obedience and the impossibility of divorcing the politically from the morally right.

Gorgias holds that "rhetoric" is an "art," the application of knowledge to practice, and the queen of all "arts," since it gives its possessor the object of man's highest ambition, power to enforce his will on society. The statesman, who is the man of men, is just a consummate advocate speaking from a brief. If he is clever enough he will, though a layman, carry the day with an audience of laymen, even against the expert specialist. To his audience he will seem, though he is not, the superior of the real expert. Socrates declares that "rhetoric" is not an "art," a matter of native principles, but a mere "empiric knack" of humouring the prejudices and pleasing the tastes of an audience. It is a subspecies of parasitism.

There are two genuine arts conducive to the health of the body, those of the trainer and of the physician; each has its parasitic counterfeit, the one in the profession of the beautifier, the other in that of the confectioner. So there are two arts conducive to health of soul, those of the legislator, who lays down the rule of morally sane life, and of the judge, who corrects moral disorders. The sophist counterfeits the first, as the rhetorician the second, by taking the pleasant instead of the good as his standard. The

rhetorician is thus not the wise physician of the body politic but its toady.

This severe judgment is disputed by Polus, the ardent admirer of Gorgias, on the ground that the successful rhetorician is virtually the autocrat of the community: every man's life and property are at his mercy. To be such an autocrat is the summit of human happiness; even if, like Archelaus of Macedonia, the aspirant only reaches the position by a series of shocking crimes, he is the most enviable of mankind, because he is above law and can do whatever he likes.

Socrates rejects this view. The autocrat always does "as he pleases," and for that reason never does "what he wishes"; as all mankind, he wishes for true happiness or good, but no act which is immoral ("unjust") ever leads to happiness. To suffer a wrong is an evil, but to inflict one is much worse. And if a man has committed a wrong, it is much worse for him to go unpunished than to be cured of his moral malady by the sharp but wholesome medicine of punishment. If rhetoric is of real service to men, it should be most of all serviceable to an offender. If he knew his own interest, he would employ all his powers of persuasion to move the authorities to inflict the penalties for which the state of his soul calls. Polus is unable to meet this reasoning, because he had at least conceded to current morality that it is more disgraceful, though not more evil, to inflict wrong than to suffer it.

This is denied by Callicles of Acharnae, an otherwise unknown politician, who proceeds recklessly to develop the doctrine of the "will to power." It may be a convention of the herd that unscrupulous aggression is discreditable and wrong, but "nature's convention" (a phrase which appears here for the first time in literature) is that the strong are justified in using their strength as they please, while the weak "go to the wall." Callicles and Socrates thus appear as champions of two contrasted moralities of private and public life. Callicles stands for self-assertion in ethics and aggressive imperialism in politics. Socrates opposes both. In his judgment the creators of the imperialistic Athenian democracy were no true statesmen, because they were content to give Athens a navy and a commerce without creating a morally sound national character. They may have been capable domestic servants of the democracy for whose tastes they catered; they were not its physicians. The one true statesman of the past was the just Aristides; in the present, Socrates himself is the one man who shows a statesmanlike mind, though it is perfectly true that he might at any moment have to pay with his life for refusing to call that good which pleases the public fancy. It is not true, as Callicles supposes it to be, that the secret of happiness is to have strong and vehement passions and be able to gratify them to the full. That would be a condition like that of the fabled sinners who are punished in Hades by being set to spend eternity in filling leaking pitchers. The truly happy life is that of measure in which the gratification of desire is strictly regulated by regard for justice and *sophrosyne*. If we may believe the Orphic doctrine of judgment to come, the votary of passion and injustice has a heavy reckoning to await hereafter.

Meno.—The *Meno* is nominally concerned with the question of what virtue is and whether it can be taught, but it is further interesting for two reasons. It states clearly the doctrine, which we have not met so far, that knowledge is "recollection"; it also introduces as a character the democratic politician Anytus, the main author of the prosecution of Socrates. It seems plain that Plato wishes to indicate his opinion that it was Socrates' severe criticism of the great figures of the history of Athenian democracy which led to the prosecution.

Can virtue be taught or learned (as must be the case, if the professional sophists can really do what they profess)? That depends on what virtue is. We are on the way to define it as "ability to secure good things by honest means," when we reflect that honesty itself is a "good thing," and the definition consequently is circular. This reminds us of the current dilemma that all such inquiries are futile because it is idle to inquire into what you already know, useless to inquire into what you do not know (since you could not recognize the unknown, even if you found it). This difficulty would vanish if it were true that the soul is immortal and has long

ago learned all truth, so that it needs now only to be reminded by sense-experiences of truths which it once knew and has forgotten. This (Orphic) doctrine seems to be supported by the experience that a lad who has never studied geometry can be brought to recognize mathematical truths by merely showing him a diagram and asking him appropriate questions about it. He produces the right answer "out of himself." (The point thus is the presence of an *a priori* element in mathematical truth.)

In any case, we may say that if "virtue" is knowledge, it can be taught; if it is not knowledge, it cannot. But is it knowledge? If it is, one would suppose that there must be professional teachers of it. But Anytus assures us vehemently that the sophists, who claim to be such professionals, are mischievous impostors, and we can be sure that the ordinary decent citizen cannot "teach virtue," as Anytus maintains, since the "best men" of the democracy, Themistocles and the rest, have been unable to teach it to their own sons. Perhaps, then, we must say that the "best men" of Athens have no genuine knowledge of good; their successes have been due not to knowledge, but to mere correct opinions. Still, for practical purposes a correct opinion will serve as well as knowledge. The trouble is that you cannot depend on its permanency unless you fasten it down by thinking out the reason why of it. Then it becomes knowledge. If a man should arise who could actually teach statesmanship to others, he would be one who really *knew* what good is; the virtue of such a scientific statesman would be to that of other men as substance is to shadow.

Protagoras.—This finely dramatic dialogue gives us the most complete presentation to be found in Plato of the main principles of the Socratic morality and is the direct source of Aristotle's statements about the teaching of Socrates in the *Nicomachean Ethics*.

Socrates meets, in the house of Callias, the eminent sophist Protagoras, who is attractively drawn and represented as a great admirer of the younger man's ability. Protagoras explains that his profession is the "teaching of goodness," and that by "goodness" he means the art of making a success of one's own life, of one's household and of one's city. (Thus he teaches the conduct of life, private and public, and has done so for years with success.) Socrates urges that there are two considerations which make it look doubtful whether this art can be taught. The Athenians have a high reputation for intelligence, but it is notorious that their assembly requires no evidence of expert knowledge in a speaker who discusses the morality of a proposed course of action.

Also the eminent democratic statesmen have never taught their own "goodness" to their sons. Public opinion and the practice of the eminent few alike suggest that the conduct of life is not teachable. Protagoras, to be sure, thinks that the absence of special teachers only proves that every citizen of a civilized city can, in his degree, act as teacher, exactly as he can teach his children his native language or his trade. Goodness depends on the sense of right and conscience, and the whole of life in a civilized society is a process of education in these. His exposition at once raises the problem of the unity of virtue. Are the various commonly recognized virtues really different, so that a man may be strong in one but weak in another? Protagoras is at first inclined to say that they are, but on reconsideration is ready to identify all of them but one with wisdom or sound judgment.

An exception must be made for courage, a virtue which is popularly regarded as having something conspicuously nonrational about it. The dialogue culminates in an argument by which Socrates attempts to show that there is no need to make this exception. The general public, the party which insists so much on the nonrational character of courage, would be ready to accept the identification of the good and the pleasant and to grant that the goodness of courage means that by facing pain and danger one escapes worse pain or danger. On their own theory, then, courage and the rest of virtue can be reduced to prudent computation of pleasures and of pains. The humour of the situation is that Socrates and Protagoras have thus changed places. Socrates, who had raised a difficulty about the teachability of virtue, is left satisfied that virtue must be knowledge; Protagoras, who claimed to be able to teach it, ends by declaring that, whatever virtue may

be, it cannot be knowledge. It is important to observe that the dialogue does not teach hedonism. The equation *good = pleasant* is advanced only as one which would be accepted by the mass of men, and should forbid them to find a paradox in the identification of virtue with knowledge; it is expressly repudiated by Protagoras as unworthy of a man of high character.

All that Socrates asserts is that virtue is knowledge and wrongdoing consequently involuntary. There is no disagreement in moral principle between the *Protagoras* and the *Phaedo* or the *Gorgias*. If the mass of men are ready to accept the hedonist formula, that is because they are votaries of the body-loving life; this is why we are told in the *Phaedo* that "popular" virtue is illusory. The true explanation of Socrates' doubts is that, though he holds that true virtue, being knowledge, is teachable, he does not believe that what Protagoras is trying to teach is true virtue. Success depends on personal tact and tact cannot be learned from an instructor.

Euthyphro, Apology, Crito.—The main purpose of these three works, which deal with the bearing of Socrates before, during and after his trial, is to obviate possible serious misunderstandings of his position and motives; the theme of all three may be said to be the true meaning and importance of care or tending of the soul.

The problem of the *Euthyphro* is what is religion. The respondent Euthyphron is certainly meant to be a kind of Orphic sectary, not, as has been fancied, a representative of ordinary Athenian belief and practice. Socrates had associated with such men and was known to hold unusual beliefs about the soul; hence it was important to make it plain that he was something different from a fanatic. The dialogue, interesting also from its well-developed logical terminology, enables Socrates to repudiate immoral mythology and to reject the conception of "religious duty" as fulfilment of purely arbitrary commands. Its central thought, which, however, is not formally asserted as a conclusion, is that the service of God which in religion means co-operation with God and under God in the production of a noble work, the nature of which is not further defined, though it is sufficiently clear that the "work" meant is the "tending of the soul."

Consideration of the *Apology* and *Crito* in detail belongs rather to the study of Socrates than to that of Plato. Of the *Apology* we must be content to say here that the real defense of Socrates is contained in the pages which explain that the main-spring of his life has been his conviction that he has a mission from God to spend his life in "philosophy," the endeavour to "make his own soul as good as possible," and to incite mankind to do the same; to this mission it is his duty to be strictly faithful, even if faithfulness means condemnation as a traitor by the democracy. The *Apology* thus depicts Socrates as carrying out in his own practice the ethical program of the *Gorgias*. The actual accusation is treated with contempt and satirical humour. (See **SOCRATES**.)

The point of the *Crito*, though simple, is often missed. Was Socrates wantonly throwing away a valuable life by refusing to escape from prison? Why did he make this refusal? Because, though the conviction was materially iniquitous, it was the verdict of a legitimate court, which could not be disregarded without real disloyalty. Socrates has been wronged not by the law, but by politicians who have abused the law. If he disregarded the conviction, he would be directly doing a wrong against the whole social system.

Foundation of Plato's Doctrine.—In the works so far considered we have the foundation of a moral and political doctrine based on Socratic principles, from which Plato never departed. The main underlying thought is that the great concern of man, a concern not limited to this earthly life, is the development of a rational moral personality (the tending of the soul). Our felicity depends wholly on our success in this task (to use J. Butler's language, on "our conduct," not on "our condition"). And this success, again, depends on rational insight into the true scale of good. It is not because they do not desire it that men fail to attain felicity: on the contrary, no man ever really desires anything else. The reason why men forfeit felicity is that they mis-

take apparent good for real, the conditionally for the absolutely good. If a man ever knew with assurance what absolute good is, he would in practice never pursue anything else. It is in this sense that "all virtue is knowledge" and that "all wrong-doing is involuntary" (*i.e.*, consists in the pursuit of what is falsely supposed to be good).

"Popular morality" is confused in theory and unreliable in practice because it does not rest on any assured insight into absolute good; "philosophic morality," just because it does rest on such certain insight, is a morality of absolute and unconditional obedience to conscience, such as Socrates had shown. Since the task of the statesman is simply the task of tending the soul extended to the national soul as its object, the philosophical moralist is also the only true statesman. True statesmanship means the promotion of national character as the one thing which matters, and is therefore simply the application, on the grand scale, of the principles of absolute morality; what falls short of this is opportunism masquerading as statesmanship.

These convictions clearly imply a far-reaching metaphysic as their foundation and justification. The principles of this metaphysic, though they are frequently hinted at in passages of dialogues already reviewed, are put before us more explicitly in those which we have now to consider; in connection with them we shall also observe an explicit theory of knowledge and scientific method.

Phaedo.—The *Phaedo* is often treated as though its object were to provide a demonstration of the immortality of the soul. It does not really profess to do this. The object is to justify faith in immortality as a rational faith by showing that it follows naturally from a fundamental metaphysical doctrine (the ideal theory or doctrine of forms), which seems to afford a rational clue to the structure of the universe, though it is expressly said at the end of the whole discussion that this doctrine itself still requires further examination. At the same time, it is made fully clear that the writer accepts this metaphysical doctrine, with the reservation just mentioned, and is passionately sincere in the faith in "personal immortality" which he brings into connection with it. To be strictly accurate, indeed, we ought to say that the faith to be defended goes beyond belief in immortality. What is being maintained is the divinity of the soul; its survival of death is a consequence of this inherent divinity.

The argument is briefly as follows: A true philosopher may naturally look forward to death without dismay. For death is the separation of soul from body, and the philosopher's whole life has been spent in trying to liberate the soul from dependence on her body. In life, the body is always interfering with the soul's activity. Its appetites and passion interrupt our pursuit of wisdom and goodness; its infirmities are perpetually hindering our thinking. Even in our scientific work, we only attain exact and certain truth in proportion as we detach ourselves from reliance on sense-perception and learn to depend on pure thinking.

Death, then, only completes a liberation which the philosopher has been "rehearsing" all through life—if, that is, the soul continues to exist after death, as there are reasons for thinking. For:

1. There is a belief that the soul has a succession of many lives and that, when it is born into this world, it has come back from another; and there are two considerations to be urged on behalf of this belief. In the first place, the processes of nature in general are cyclical: the hot becomes cold, the cold hot; the waking go to sleep, the sleeping wake. It is reasonable to suppose that this applies to the case of dying and coming to life, so that the dead return to life, just as the living die. If this were not so, if the process of dying were not reversible, life would ultimately vanish from the universe. Secondly, we may appeal to the doctrine that what we call "learning" is really "recollection," being reminded of something. This certainly seems to be the case, for in all our science we are perpetually being put in mind of precise ideal standards, mathematical or moral, with which sense or experience never presents us. We must therefore have become acquainted with them before we were confined to our bodies, and therefore must have existed before our birth. These two considerations together would prove what we want to prove, the soul's survival of death, though our dread of the dark makes us

demand a more convincing argument.

2. We may consider the antithesis between the divine and eternal and the temporal and mutable, which runs through the universe. The body is certainly temporal and mutable. The soul is relatively immutable, like the fixed ideal standards or norms which she contemplates in her scientific thinking. Her thought is concerned with eternal objects and she herself has the likeness of that which she contemplates. If, then, some constituents of the body are nearly indestructible how much more should one expect the divine element in us, the soul, to resist destruction, as the traditions about rebirth assert that it does.

There are two grave "scientific" difficulties still to face. It may be argued: (1) that the soul is an epiphenomenon, the tune (*harmonia*) given out by the body, and if so, its superior divinity will not protect it from vanishing when the instrument which makes the music is broken; (2) that though the soul actually makes its own body, and perhaps can make a long succession of bodies, it cannot do so without expending energy, so that a time will come when it can no longer make a fresh body, and then it will itself disappear. We must not be driven into misology, antipathy to science, by this apparent clash between science and a faith to which we are attached.

The answer to (1) is that there are good souls and bad ones, and the good soul is more in tune than the bad one. But that which can be more or less in tune is clearly not itself a tune. And if the soul were the tune resulting from the functioning of the body, its character at any moment would be a resultant of the condition of the body. How then could we have the experience, characteristic of the moral life, of the conflict between the soul with its aspirations and the body with its carnalities? The answer to (2) can only be given as part of a whole theory of the causes of "coming into being and passing out of being." Socrates had been led, early in life, to frame a tentative theory of the matter in consequence of his dissatisfaction with the chaotic state of physical speculation and in particular with the failure of Anaxagoras to make any satisfactory use of his apparently teleological principle that "mind is the cause of all order and structure." He fell back on the method of "hypothesis."

What distinguishes this method from all others is that it begins by making an undemonstrated postulate (*hypothesis*). It then proceeds from this point to consider the truth or falsehood of the consequences which follow logically, from the initial postulate; the question of the truth of the postulate is, for the present, left unasked. Socrates' own fundamental unproved postulate has always been that usually, but loosely, called the theory of ideas. The postulate is that there really is a single determinate and immutable something answering to every significant general term and apprehended only by pure thought. The sensible things of which we predicate general terms temporarily partake in or communicate with the idea or form (*idea, eidos*). When we say that a thing becomes beautiful, what we mean is that the form "beauty" begins to be present to that thing, the thing begins to partake of the form. When we say that a thing ceases to be beautiful, we mean that this relation of presence, participation, communication is dissolved. This is the true account of the cause of "coming into and passing out of being," and if we accept it, we may proceed to our final argument for immortality.

3. There are forms which are mutually incompatible, such as warmth and cold. Heat is never cool, and cold is never warm. But there are also certain sensible things of which it is an essential character to partake of a given form. Such things will never admit an incompatible form. Thus it is an essential character of snow to partake of cold. It will never, therefore, partake of the form heat. Similarly it is an essential character of a soul to be alive, to partake of the form life. It refuses to partake of the form death. At the approach of death, the soul must either retire or be annihilated (the metaphors are military). What we have said of its divinity forbids us to think that it is annihilated; we must therefore assume that it retires to some other region. The proof of immortality is thus hypothetical; it is shown to be involved as a consequence by the doctrine of forms. This doctrine has been stated as a fundamental unproved postulate and it is

admitted that it demands fuller consideration.

But our inquiry has at least satisfied us that the hope of immortality is a reasonable one. (To distrust it would be to call the foundation of our whole philosophy into question.) The discourse ends with an imaginative cosmological myth depicting the future of the just and the unjust, respectively.

In this statement of the theory of forms we may note the following points: (1) The doctrine is a piece of realist metaphysics in so far as it is assumed that a universally predicated general term denotes or stands for an individual reality, apprehensible by thought, though not by sense; (2) there are a plurality of such forms, standing in various logical relations with one another (whether they constitute a system with a definite structure the *Phaedo* does not tell us); (3) they are at once the objects known in all genuine science and the formal causes of all the temporal processes of the sensible world; (4) the sensible things which have the same names as forms are said to owe their character to their participation of the forms, or, equivalently, to the presence or communication of the forms to them, though the precise character of this relation of participation is admitted to need further explanation (so far as the language of the *Phaedo* goes, a sensible thing would seem to be thought of as a temporary complex or meeting place of universal characters and as nothing more).

Symposium, Phaedrus.—It is by no means clear that these two dialogues are closely connected in point of date, but they may be considered together as both presenting the forms in a special light, as objects of mystical contemplation and excitant of mystical emotion.

The argument of the *Symposium* cannot be reproduced here as a whole. The immediate object of the dialogue, which professes to record the discourses made in eulogy of Eros by a group of eminent speakers at a banquet in honour of the tragic poet Agathon, in the year 416–415, is to find the highest manifestation of the love which controls the world in the mystic aspiration after union with the eternal and supercosmic beauty; to depict Socrates as the type of the aspirant who has reached the goal of union; and to set in sharp opposition to him the figure of Alcibiades, who has sold his spiritual birthright for the pleasures and ambitions of the world. The centre of philosophical interest lies in the discourse of Socrates, which he professes to have learned a quarter of a century ago from the priestess Diotima of Mantinea.

The main argument may be summarized thus: Eros, desirous love, in all its forms, is a reaching out of the soul to a good to which it aspires but has not yet in possession. The desirous soul is not yet in fruition of good. It is on the way to fruition, just as the "philosopher" is not yet in possession of wisdom but is reaching out after it. The object which awakens this desirous love in all its forms is beauty, and beauty is eternal. In its crudest form, love for a beautiful person is really a passion to beget offspring by that person and so to attain, by the perpetuation of one's stock, the *succedaneum* for immortality which is all the body can achieve. A more spiritual form of the same craving for eternity is the aspiration to win immortal fame by combining with a kindred soul to give birth to sound institutions and rules of life. Still more spiritual is the endeavour, in association with chosen minds, to enrich philosophy and science with noble discourses and thoughts.

But the goal still lies far ahead. When a man has followed the pilgrimage so far, he suddenly descries a supreme beauty that is the cause and source of all the beauties discerned by him so far. The true achievement of immortality is finally effected only by union with this. The philosopher's path thus culminates in a supreme beatific vision. It is clear that the object of this vision, the beauty sole and eternal of the dialogue, means what the *Republic* calls "the good" or "form of good" which by its presence actually causes the goodness of everything else to which the name of good can be given. The forms are thus thought of as a hierarchy with a supreme form at their head, though no attempt is made at a rational theory of the way in which the supreme form unites the rest into the system.

The immediate subject of the *Phaedrus* is the principles of rhetoric or, as we should say, prose composition. The *Gorgias*

had told us that rhetoric as commonly practised is not a matter of rational principles at all, but a mere empirical trick of adapting one's tone to the prejudices of an audience. The *Phaedrus* aims at showing how a really scientific rhetoric might be built on the double foundation of logical method and scientific study of human passions. Plato contrives, however, by making a real or supposed "erotic" composition of Lysias the starting point of his criticisms, to unite with this topic a discussion of the psychology of love, and this, as in the *Symposium*, leads him to speak of the forms as the objects of transcendental emotion. The soul is immortal, because it has within itself a native source of spontaneous movement. (This is the argument for immortality to which Plato trusts in the *Laws*. It is not specially mentioned in the *Phaedo*, but this can hardly mean that Plato had not yet discovered it, since it is, in fact, taken from Alcmaeon of Crotona, a medical man of the beginning of the 5th century.) In its disembodied state it shared the life of the gods and could enjoy the direct contemplation of unbodied reality—that is, of the forms. It has suffered an antenatal fall into an embodied condition in which it is blind to everything which does not come in at the avenues of sense.

Now our senses only suggest few and faint images of such forms as justice and temperance, but they can suggest beauty in a much more impressive and startling way. To fall in love is to come under the influence of such sudden and arresting suggestions of beauty; the unreason and madness of the lover mean that he is being awakened to realities which other men ignore. The wings of his soul are beginning to grow again, and his experience, rightly used, will be the first step in the soul's return to its high estate. This section of the *Phaedrus* is the *locus classicus* in Plato for the forms as objects of mystical contemplation.

Republic.—The philosophy presupposed in all these dialogues receives its fullest exposition in the *Republic*. Here the immediate problem is strictly ethical. What is justice? Can it be shown that justice is always a boon, injustice a curse, to its possessor, apart from all consideration of consequences in this life or another? That is, is there a rational principle at the root of moral distinctions, and does the principle carry with itself its own intrinsic and indefeasible authority?

Plato's answer is that there is such a principle; each of us, in virtue of his special endowments and aptitudes, has a specific work or vocation; there is some special contribution which he, and no other, can make most effectively to the life of a rational society. Morality, justice, is to discharge that vocation to the height and with a single mind. To live thus is to be in spiritual health; to live otherwise is to be spiritually diseased. The obligation is thus intrinsic and absolute. This position has to be made good against the incoherencies of a morality of uncriticized traditional maxims, as well as against the immoralism of advanced thought (represented by Thrasymachus in book i, expounded more intelligently by Glaucon in book ii).

This leads us to consider what would be the general type of life in a society where the principle of justice had power as well as manifest authority, and how it might acquire that power. Hence the need for a sketch (books ii–iii) of the institutions of the reformed society, and particularly of its moral and religious education. We have next to satisfy ourselves that the principles which regulate the public life of the morally healthy society are also recognizably the principles of the great virtues of private life. For this purpose, we need a psychology of voluntary action which is provided (book iv) by the doctrine of the tripartite soul. This is not, indeed, a scientific psychology, but proves adequate to describe the moral life of the ordinary good citizen of such a society as we have conceived. The foundation of all this moral excellence is thus laid in absolute loyalty to a sound moral tradition enforced by education.

To ensure that the tradition shall be thoroughly sound, we must stipulate that the authorities who create it do not themselves depend on tradition for their convictions about good and evil; they must not opine, but know, by personal insight. The statesmen at the head of the community must be "philosophers" as well as kings (book vi).

But the vision of "the good" will only dawn on them if they

have been prepared for it by an intellectual discipline in hard thinking which leads them through the curriculum of the exact sciences to the critical study of the metaphysical principles involved in science (book vii). The central books of the *Republic* thus present us with an outline of metaphysics and a philosophy of the sciences. We now turn back to consider the various stages of degeneration through which national and personal character pass when the true moral ideal is allowed to fall more and more completely out of view. As we pass them in review, we are increasingly confirmed in our conviction that, in respect of happiness, the life of regard for right is immeasurably superior to that of sating one's cupidities or gratifying one's personal ambitions (books viii and ix), and this conclusion is finally clinched (book x) by re-affirmation of the immortality of the soul. Since the soul is immortal, the issue which hangs upon our choice to live well or ill is one of infinite moment.

The ethical scheme of the *Republic*, like that of the *Gorgias* and *Phaedo*, is dominated by the conception of the "three lives," ascribed by Heraclides Ponticus to Pythagoras. The "lives" are those of the philosopher, of the man of action and of the votary of enjoyment. The end of the first is wisdom, of the second, distinction, of the third, the gratification of appetite. Distinction is a worthier end than mere satisfaction of appetite; the supremely worthy end is wisdom. In a well-lived life, then, the attainment of wisdom will be the paramount end, and ambition and appetite will be allowed only such gratification as is compatible with loyalty to the pursuit of that paramount end. The psychological foundation of this doctrine is the theory of the tripartite soul, expounded fully in book iv. Analysis of familiar experience reveals three elements or active principles within us: (1) considered rational judgment of good; (2) a multitude of clamant appetites for particular gratifications, which may be in violent conflict with our own considered judgment of good; (3) a factor of spirit higher ideal emotion, which manifests itself as resentment against both the infringement of our just rights by others and the rebellion of our own appetites against our judgment.

The same distinctions reappear in the structure of society. A society naturally falls into three divisions: the statesmen, who direct the public life; the general civilian population, who carry on the business of providing for material needs; and the executive force (army and police), whose function is, in a rightly ordered society, to give effect to the counsels of the statesmen by repressing attacks from without and rebellion from within.

These three orders are thus respectively, the judgment, the appetitive element and the spirited element in the national soul. On this basis, we can proceed to work out an ethical and political theory. In ethics we can define the great types of goodness, the quadrilateral, later known as the cardinal virtues. Wisdom is the excellence of the thinking part, clear and assured knowledge of the good; courage, the fighting man's virtue, is the excellence of the spirited part, unswerving loyalty, unshaken by pain, by danger, by the seductions of pleasure, to the rule of life laid down by judgment; temperance, the special excellence of the appetitive part, is the contented acquiescence of the nonrational elements in the soul in the plan of life prescribed by judgment; justice is just the state in which each of the elements is vigorously executing its own function and confining itself within the limits of that function. In the rightly ordered society, the national wisdom has the statesmen as its organ, the national courage the executive force; the national temperance is shown in the loyal contentment of each class in the community with its prescribed place and its duties.

Such a society is a true aristocracy, or rule of the best. Timocracy, the military state, in the better sense of that phrase, arises when the mere man of action, only competent to fill the part of a good soldier, takes the place which rightly belongs to the thinker as directing statesman. Oligarchy (e.g., the dominance of merchant princes, plutocracy) is a further deviation from the ideal, which arises when political power is bestowed on property as such. A still worse system is democracy, in which no attempt is made to connect political power with any special qualifications. Worst of all is tyranny, exercise of irresponsible power by the positively

disqualified, the man of criminal will. The psychological scheme on which this construction is based is not given by Plato as a piece of strict science. We are carefully warned that exact truth is not to be reached by such an analysis of *prima facie* facts of social life (435 d) and reminded later on that this apparent triplicity of the soul may prove to be only a temporary consequence of its conjunction with the body (611 b). The tripartite psychology, it is meant, enables us to give an account of the moral life, as it actually appears in a good citizen, which will fairly describe the facts. It is good popular psychology, useful for the moralist, but it is no more.

Hence it is improbable that the analysis originated with Plato himself. More probably it was, as the Stoic Poseidonius asserted, a piece of earlier Pythagorean doctrine, as is also suggested by the constant recurrence, throughout the section of the *Republic* in which the analysis is offered, of analogies from the specially Pythagorean science of harmonics; and by the fact that the same doctrine is taught by the Pythagorean speaker in the *Timaeus*. Plato has, however, worked the theory into his ethics so completely that through him it has actually become a part of the psychology of Thomism, where it has to be squared, not quite satisfactorily, with the radically divergent psychological scheme of Aristotle.

In point of fact, the tripartite schema proves inadequate in the *Republic* itself when we advance in book vi to the consideration of the moral life of the philosopher-king, whose virtue is founded on a personal knowledge of good. A higher level of moral goodness is demanded of him than of other citizens even of the ideal state; his courage, for example, is declared to be no mere loyalty to right opinions inculcated by early education, but a high serenity arising from the knowledge of the relative insignificance of a brief individual life in the great universe which lies open to his contemplation. This has an important bearing on the teaching of the *Republic* about the unity of virtue.

In the ideal state itself, virtue does not appear as a complete unity. The leading types of moral excellence receive their several definitions. It is recognized that a special demand may be made on a particular section of the society in respect of a particular virtue of which it is, so to say, the public organ, as the fighting force is of the valour of the whole society. This is because, even in the ideal state, the moral convictions of citizens, other than the men of superlative intelligence and character who become kings, are not supposed to arise from personal insight. They rest on opinions implanted by education and are thus taken on trust. The good civilian or soldier, after all, is not living by a knowledge which is his own. But the rulers, by whose knowledge the rest of the community lives, must not, of course, themselves take their convictions on trust. They must know with a personal knowledge. The foundation of their virtue must be insight into a system of absolute values embodied in the very structure of the universe. In virtue of this deeper foundation the virtues in them are, so to say, substantiated and can no longer be distinguished from one another. They will fuse in knowledge of the good, as, in the Christian saints, they are fused in knowledge and love of God. It is in this form that the Socratic doctrine, "all virtue is one thing, knowledge" reappears in the *Republic* as the foundation of a society in which mankind has at last "escaped from its wretchedness," because knowledge rules.

In the *Republic*, as in the *Phaedo*, the forms appear in the double character of objects of all genuine science and formal causes of the world of events and processes. It is expressly denied that there can be knowledge, in the proper sense of the word, of the temporal and mutable. In the scheme laid down for the intellectual training of the philosophic rulers, ten years, from the age of 20 to that of 30, are assigned for systematic study of the exact sciences in the order: arithmetic, plane geometry, solid geometry, astronomy and harmonics. Special stress is laid on the points that the object of these studies is not practical applications but the familiarizing of the mind with relations between terms which can only be apprehended by thought, and that diagrams and models are to be treated merely as incidental aids to imagination. Five years are then further to be given to the still severer study which Plato calls dialectic,

a study which avails itself of no sensible aids to imagination. It proceeds "by means of forms, through forms, to forms" (511 *b*). It is, in fact, what we should call a critical metaphysic of the sciences. It examines the *hypotheses* or unproved postulates, of the various sciences, and its object is to destroy their character as unproved ultimate postulates (533 *c*) by discovering some still more ultimate really self-evident principle (511 *b*) from which they follow as consequences.

There can be no doubt that this most ultimate principle which is more than a postulate means the good or form of good which is said to be the source at once of the reality and the knowability of all that is real and knowable, though it is itself neither knowledge nor being, but transcendent of both (509 *b*). On the methodological side the *Republic* thus completes the teaching of the *Phaedo* by providing the answer to the question then left open, when a postulate may be regarded as finally established. It may be so regarded when it is seen to follow itself from the good, which is the principle at once of existence and of value.

Socrates is made to confess (506 *d-e*) that he can give no positive account of this supreme metaphysical principle; he can only indicate its nature by an analogy. It is to the whole system of forms what the sun is to the system of visible things, the source at once of their existence and of the light by which they are apprehended. The good is thus thought of, to use scholastic terminology, as a transcendent reality which can be apprehended but never fully comprehended. The comparison with the sun and the free employment of the metaphor of vision indicate that the thought of the *Republic* is here the same as that of the *Symposium*: the good is no other than the supreme beauty which was there said to dawn suddenly upon the pilgrim of love as he draws near to the goal of the journey. R. L. Nettleship rightly says that it holds the place taken in later philosophies by God, when God is thought of as the "Light of the world." But it would be deforming Plato's thought to call the good of the *Republic* God. The *Republic* is permeated by religious faith, but theism as a principle of metaphysical explanation only makes its appearance in Plato's latest dialogues, and there as the solution of a problem which can hardly be said to have been adequately faced in the dialogues so far considered.

How the good gives systematic structure to the plurality of forms, the *Republic* does not tell us.

Development of the Doctrine of Forms.—So far we have been presented with a body of thought which has remained recognizably the same without serious modification throughout its various expositions. When we come to the two works which there is reason to regard as directly prelude to the dialogues of Plato's old age, the *Parmenides* and *Theaetetus*, we are struck by a remarkable difference of tone. With Plato, as with Kant, the middle years of life were clearly a period of fruitful critical reconstruction. There is an obvious motive for each reconstruction suggested by the *Phaedo* and *Republic* themselves.

The theory there expounded does not allow enough reality to the sensible world. It is quite false to say that even the *Phaedo* teaches an absolute dualism of two disconnected worlds, a realm of genuine being which never appears and a realm of sensible appearances which are merely unreal. What is true is that both *Phaedo* and *Republic* leave us with an unsolved problem. They tell us that a sensible thing is a complex or meeting place of a plurality of forms. What else, or what more, it is they do not tell us. And yet it is clear that a thing is not simply a bundle of universal predicates.

Or, to put the point rather differently, according to the *Phaedo* a thing becomes for a while beautiful because beauty "becomes present to it." But why does beauty become present to this particular thing at just this particular moment? Clearly the relation between a thing and a form which has been called participation needs further elucidation. Again the simple epistemological formula that knowledge is confined to forms and their relations, while we can only have shifting opinions about temporal facts does less than justice to our scientific knowledge of the natural world; truths of fact have not yet come by their rights. Finally, if the forms constitute a rationally ordered system, there must be definite

principles of interrelation between forms themselves as well as between forms and sensible things and these principles demand investigation. (If the good is what the *Republic* says it is, not only will things "participate" in forms; forms also will "participate" in it.) Here are internal motives for active re-examination of the whole system.

It is clear that there was also an external motive. The *Parmenides*, the *Theaetetus* and the *Sophistes* all reveal a special interest in the Eleatic philosophy, and the first and third show an anxiety on Plato's part to maintain that, in spite of important divergences, he, and not the professed Eleatics, is the true spiritual heir of Parmenides. This is easily explained when we remember that Plato was personally a friend of the chief representative of Eleaticism among the Socratic circle, Euclid of Megara, while Polyxenus of Megara, an associate of Euclid, was a hostile critic of the doctrine of participation. The doctrine of Euclid, like that of Parmenides was that sensible appearances are illusions with no reality at all. Against criticism from this quarter, it would be necessary for Plato to show that the *Phaedo* itself does not allow too much reality to the sensible; the attempt to prove this point would inevitably show that it had conceded too little. Continued reflection on the same problem of the worth of propositions about sensible fact leads straight to the discussion of the meaning of the copula, and the significance of denial, which is the subject of the *Sophistes*.

Parmenides.—Formally the dialogue conducts to an impasse. In its first half the youthful Socrates expounds the doctrine of the participation of things in forms to the Eleatic philosophers Parmenides and Zeno as the solution of the problem of the one and the many. Parmenides raises what appear to be insoluble objections to the conception of participation, though he admits that dialectic would be impossible if the existence of forms were denied; he hints that the helplessness of Socrates under his criticism arises from insufficient training in logic.

In the second and longer half, Parmenides gives an example of the logical training he recommends. He takes for examination his own thesis, the one is, and constructs an elaborate set of antinomies after the fashion of Zeno, apparently proving that whether this thesis be affirmed or denied, in either case we are compelled either to affirm simultaneously or to deny simultaneously a series of contradictory predicates, alike of the one and of the many. The conclusion is patently ironical, and we are left to divine the author's purpose, if we can.

The objections to participation, which is formulated precisely as in the *Phaedo*, are directed not against the existence of forms, but against the possibility that sensible things should participate in them. From the point of view of this criticism Socrates' error is that he attributes some sort of secondary reality to the sensible. The main arguments are two. First, the doctrine does not really reconcile unity with plurality, since it leads to a perpetual regress. It says that the many things which have a common predicate participate in or imitate a single form. But the form itself also admits of the common predicate, and there must therefore be a second form, participated or imitated alike by the sensible things and the first form, and so on endlessly. We could not escape by the suggestion that the form exists only in our minds, since that would mean that a form is a thought, and it would follow that things are made of thoughts. But if so, either everything thinks, or there are thoughts which do not think, and both alternatives are absurd. Secondly, a graver difficulty is that if there are two realms, a realm of forms and a realm of sensible things, the relations between forms must belong to the realm of forms, those between sensible things to the realm of things. We ourselves belong to the second, and therefore all our knowledge belongs to it too; we know nothing of the true realities, the forms: if anyone knows them, it is God, but God's knowledge, being knowledge of realities, will not extend to our world, the sensible. The purpose of the objections is thus to suggest that the manifold of sense has not even a derivative reality; it is mere illusion.

This is precisely the position of the Eleatics and their Megarian continuators. The inference is that Plato is reproducing Megarian criticisms of the doctrine ascribed by himself to Socrates, an in-

ference confirmed by the notice preserved by Alexander of Aphrodisias (on *Metaphysics* 990 b 15) of the "third man" argument of the Megarian Polyxenus against participation. Plato does not indicate his own opinion of the cogency of the reasoning, which is, in fact, fallacious, as was properly pointed out by Proclus. (For a detailed discussion of it, see A. E. Taylor, "Parmenides, Zeno and Socrates," in *Proceedings of the Aristotelian Society for the Systematic Study of Philosophy*, vol. xvi, pp. 234 ff.)

The purpose of the antinomies which follow has been differently understood. It seems possible that they may be deliberate parody, the object being to show that the methods of the Megarian logicians are even more damaging to their own fundamental metaphysical tenet than they are to the doctrine of participation. Megarian logic is a double-edged weapon, and Plato, if he chooses, can apply it even more dexterously than its inventors.

Theaetetus.—Except for a magnificent interlude in praise of the contemplative life, the dialogue is a straightforward discussion of the question how knowledge should be defined. It naturally ends negatively. None of the proposed definitions will stand examination (the reason is that we are really trying to define truth and truth is an ultimate). But the incidental results of the discussion are of the first importance. We learn (1) that knowledge cannot be identified with sensation nor with any formless simple apprehension; (2) that pure relativism is as impossible in epistemology as in metaphysics. We have the beginning of a doctrine of the categories which is further developed in the *Sophistes*.

The increasing value which Plato is coming to put upon natural knowledge is marked by the use of the word *doxa* (which in earlier dialogues had commonly meant mere uncertain opinion) in the new sense of "judgment" which it retains in Plato's subsequent work. The most striking negative feature of the *Theaetetus* is that it discusses knowledge at length without making any reference to the forms or to the mythology of recollection. It remains to this day the best of introductions to the problem of knowledge. The main argument may be briefly summarized as follows:

1. It seems plausible at first to say that knowledge (*episteme*) is sensation (*aisthesis*). This sounds like the proposition of Protagoras, "what seems to me is so to me; what seems to you is so to you." We might base such a thoroughgoing doctrine of the relativity of all knowledge on a still more ultimate metaphysical theory, if we said—it is implied that Protagoras himself said nothing of the kind—that, within us and without us, the only reality is motion. Organ and environment are both motions; when these motions impinge on one another, they give rise to the twin product, felt sensation—sensible quality.

Both the sensation and the quality sensed will therefore be affected by any difference in the pair of slower motions which cause them (the organ and its environment), and each percipient, therefore, is confined to his strictly private world, which exists only for him. There is no common perceived world, and therefore no standard of truth or reality other than the individual percipient. A teacher does not aim, any more than a physician, at convincing his pupil of the falsity of his judgments, but at giving him useful or healthy convictions in place of harmful or diseased convictions.

The full discussion of such a theory would demand a thorough study both of the Heraclitean philosophy, which says that there is nothing but motion, and the Eleatic philosophy which says that motion is an illusion. But for our immediate purpose, a more summary argument is sufficient. It is certain that even the relativists, who hold that each man is the one infallible measure of his present perceptions, do not hold that he is the only and inerrant measure of his future sensations. A physician can often judge better than his patient whether the patient is going to have, say, the sensations of an ague. A man's own opinion whether a certain course will be expedient or good for him is often far from being the soundest. We must distinguish carefully between what the soul perceives through bodily organs—the data of sense—and what she apprehends by herself without organs. The latter class includes number, sameness, difference, likeness, unlikeness, being, good, bad, right, wrong; *i.e.*, the great universal categories of fact and value. These are apprehended not by sense, but by thinking, and as they are the formal element in all knowledge, knowledge must be found

not in our sensations, but in the judgment (*sylogismos*) of the mind upon them.

2. Is knowledge, then, true judgment? The statement implies that we know what we mean by false judgment, error. But is this the case? Error must not be confused with mere false recognition, misinterpretation of present sensation, since there are purely intellectual errors, and we find ourselves unable to explain the nature of this kind of error. And, in fact, it is clear that persuasive rhetoric may produce in the hearer judgments which are true, but have no claim to be called knowledge.

3. Finally, is knowledge "true judgment accompanied by discourse, true judgment for which we can give grounds"? This would distinguish knowledge from simple apprehension and would harmonize with the theory of those who hold that knowledge is always of complexes, never of their simple constituents. But this doctrine has difficulties of its own, and, in any case, if we say that knowledge is true judgment + discourse, the discourse meant must be a statement of the logical *differentia* of the object of which I have knowledge. The proposed definition therefore amounts to saying that knowledge is true judgment about an object + knowledge of the *differentia* of that object and so is circular.

LATER DIALOGUES

Sophistes and Politicus.—Formally these two important dialogues are closely connected. They are made to appear as a sequel to the *Theaetetus*, and a further connection is afforded between them by the fact that both are ostensibly concerned with a problem of definition, which is treated by the characteristic Platonic method of repeatedly subdividing a *genus* until we obtain the *definiendum* as a subspecies. The real purpose of the *Sophistes* is logical or metaphysical; it aims at explaining the true nature of negative predication and so as to dispose of the Eleatic thesis that the temporal and sensible realm, containing, as it does, a negative moment, must be mere unreal illusion. The object of the *Politicus* is to consider the respective merits of two contrasted forms of government, personal rule and constitutionalism, and to recommend the second, particularly in the form of limited monarchy, as most suitable to the actual condition of mankind. The *Sophistes* lays the foundations of all subsequent logic, the *Politicus* those of all constitutionalism.

A more temporary purpose in both dialogues is to illustrate the value of careful classification as a basis for scientific definition. In both dialogues Socrates is almost silent; his place as chief speaker is taken by an unnamed and very unorthodox Eleatic, who seems to be a purely fictitious character. Plato is, in fact, claiming that he, and not the formal logicians of Megara, is the continuator of Parmenides, much as Aristotle in his polemic against Xenocrates claims to be the true successor of Plato.

In the *Sophistes* the main discussion is led up to through a definition of the "sophist" as an "illusionist," a person who, by abuse of logic, produces the illusion, or false appearance, that nature and human life are alike riddled by insoluble contradictions. (This shows that the persons aimed at under the name sophist are the Megarian controversialists who make an illegitimate use of the dialectic of Zeno and Socrates). Now the sophist himself would retort that this definition is senseless, for there can be no such thing as a false statement or a false impression. For the false means "what is not," and "what is not" is nothing at all and can neither be uttered nor thought. To refute him we need to correct the fundamental thesis of so venerable a thinker as Parmenides. Either we must admit that there can be no false statements, or we must be prepared to maintain that "what is not, in some sense also is," and "what is, in some sense is not" (*i.e.*, we must explain what is the meaning of a significant negative proposition). In our theory of being we have to meet at once Parmenides and two different types of pluralist opponents of Parmenides, (1) the corporealists who say that the real, "what is," is just visible and tangible body and (2) certain friends of forms who maintain that the real is a multitude of incorporeal forms, denying that sense-perception gives us any apprehension of it. The corporealist is sufficiently refuted by the consideration that he himself cannot deny the reality of force (*dynamis*) and that force is not a body. The incorporealist friends

of forms cannot be met in this way. They regard force, or activity itself as belonging to the unreal realm of becoming. We meet them by urging that knowing is itself an activity and that we cannot deny intelligence and knowledge to the supreme reality. This means that it has a "soul" and is alive. But if life is real, movement and repose from movement must be real too.¹

This leaves us free to attack the Parmenidean monism itself. That is refuted by drawing the distinction between absolute and relative nonbeing. A significant denial, *A is not B*, does not mean that *A* is nothing, but that *A* is other than *B*. Every one of the great categorical features of reality is other than every other, and the true business of dialectic is to study the various possible combinations of these universal categories. The dialogue mentions five of them, being, identity, difference, motion and rest. (Though it is not said that this is a complete list of categories, it was treated as such by the Neoplatonists.)

The important result is thus that we have learned to think of forms themselves as an interrelated system, with relations of compatibility and incompatibility among themselves. Negation is a moment in the system of intelligible reality, and therefore its presence in the sensible realm does not stamp that realm as illusion. This is the ontological position which interests Plato; the recognition of the function of the logical copula is a consequence.

The *Politicus* has as its main result the conclusion that government by the personal direction of a benevolent dictator is not suitable to the conditions of human life, where the direction is necessarily that of a fallible man, not of a god. In an actual human society, the surrogate for personal direction by a god is the impersonal supremacy of inviolable law. Where there is such a recognized sovereign law, monarchy is the most satisfactory type of constitution, democracy the least satisfactory, but where there is no fundamental law, this situation is inverted. A sovereign democracy is preferable to an irresponsible autocrat. The dialogue is rich in thoughts which have passed into the substance of Aristotle's ethics and politics. Aristotle took directly from it the conception of politics as the architectonic practical science to which all others are subordinate; the formula of the right mean comes from it together with the *Philebus*.

Philebus.—The subject of the dialogue is a strictly ethical one, and this, no doubt, explains why it is the only dialogue after the *Theaetetus* in which Socrates is the principal speaker. The issue propounded is the question whether the good is pleasurable feeling or whether it is thought, the exercise of intelligence.

Comparison with the notices of Aristotle in the *Nicomachean Ethics* shows that this was the subject of a sharp division in the Academy, the hedonist party being led by the mathematician and astronomer Eudoxus, the antihedonists by Speusippus. Under the guidance of Socrates the question is narrowed down to a consideration of the good for man in particular, and a mediating conclusion is reached. The best life for man contains both elements but intelligence is the predominant partner.

All forms of knowledge find a place in it, but only those pleasures which are compatible with wisdom and virtue; i.e., those which are "unmixed" (not preceded by a sense of want or craving) and those of the "mixed" pleasures (the satisfactions of appetite) which are innocent and moderate. The *Philebus* contains Plato's ripest moral psychology; it is the immediate source of the famous doctrine of the mean.

Philosophically the most important feature of the dialogue is a classification adopted with a view to determining the formal character of the two claimants to recognition as the good. All components of the actual belong to one of four classes, (1) the infinite or unbounded (*apeiron*), (2) the limit (*peras*), (3) the mixture

or combination of infinite and limit, (4) the cause of the mixture. (Infinite and limit are just the two fundamental opposites of Pythagoreanism.) All the good things of life belong to the third class, that is, they are produced by the introduction of definite limit or ratio into an indeterminate continuum. (This is precisely the doctrine of the mean.) The establishment of such a ratio is a genesis into being, a process resulting in a stable being, and it is indicated that the cause or agent in such a process is always intelligence, human or divine.

There has been much discussion of the question in which of these classes the forms should be placed. The only tenable alternatives would be to put them into the class of limit or into that of the mixture (a view suggested both by the teaching of the *Sophistes* and by Aristotle's express statement that Plato distinguished two constituents within the form and advocated ably by H. Jackson). The truth seems to be that the particular classification in the *Philebus* is devised for a special purpose and that it is not intended to apply to anything but the things and processes of the sensible realm. In that case, though there is a close correspondence between what the *Philebus* teaches about stable being in the sensible realm and what, as we know from Aristotle, Plato taught about the forms, it will be a mistake to look for any actual exposition of the metaphysics of the forms in the *Philebus*.

Timaeus.—The *Timaeus* is an exposition of cosmology, physics and biology put into the mouth of the astronomer Timaeus of Locri. Though Plato avoids expressly describing the speaker as a Pythagorean, his doctrine is revealed by attentive analysis as an attempt to combine the mathematics and astronomy of the Pythagoreans with the biology of Empedocles, the real founder of Sicilian medicine. The discussion is introduced by the famous narrative of the gallantry of the prehistoric Athenians who defeated the kings of the imaginary Atlantis in their ambitious attempt to become masters of the world. The story was to have been told more in detail in the unfinished *Critias*.

Timaeus opens his discussion by drawing a distinction between eternal being and temporal becoming and by insisting on the point that it is only of the former that we can have exact and final knowledge. All accounts of the temporal can be only tentative and liable to repeated revision. Cosmology, then, at best, is not exact science. The visible world, being mutable and temporal, is a copy of a model which is eternal, and the copy is the work of God. The reason why there is a copy at all is the unceasingly active and generous goodness of God. (In the sequel Timaeus speaks of the forms which God had before Him as His model in much the same language as the *Phaedo*, except that he uses the Pythagorean word imitation, not participation, to describe the relation of sensible things to forms.)

The world, then, had a beginning. (The Academic tradition from the first was that this is not to be understood literally; Aristotle insists on taking it literally.) God first formed its soul out of three constituents, identity, difference, being. Its body was made later from the four Empedoclean elements. The world soul was placed in the circles of the sidereal equator and ecliptic, the latter being split into seven lesser circles, those of the planets, and the two were animated with movements in opposite senses. Subsequently were formed the various subordinate gods and the souls of human beings, that is the immortal and rational element in the human soul, which come straight from the hands of God Himself. The formation of the human body and of the two lower mortal components of the human soul was effected through the intermediacy of the "created gods" (i.e., the stars). The most important question of detail arising from this part of the dialogue is that debated between A. Boeckh and G. Grote. Does Timaeus ascribe a motion to the earth? The restoration of the correct text at 40 c ("going up and down on the path about the axis of the universe") proves definitely that he does, but it is not a diurnal revolution, as Grote supposed; it must be rectilinear displacement of unknown period.

The contact is made between Pythagorean geometry and the Empedoclean biology which will be needed for the physiology and medicine of the dialogue by a mathematical construction of the elements. Starting with two primitive triangles, the isosceles right-

¹It is still a much agitated question who are the logical atomists described in the *Sophistes* as the friends of forms. The view that they are adherents of the philosophy of the *Phaedo* and *Republic* is deservedly dead. They are still often supposed to be Megarians, but this seems inconsistent with the way in which they are carefully distinguished from the followers of Parmenides as belonging to the other side at 245 e. Proclus (*Commentarii in Parmenidem*, 562) says positively, as though it were the only view known to him, that they are Italian Pythagoreans, and this is probably correct, since the Eleatic of the dialogue refers to them as persons with whom he is familiar. It is important to remark that the identification of being with force is given merely as a consequence which would follow from, and contradict, the corporealist hypothesis. The implication of the passage is rather that the identification is false than that it is true.

angled, and the right-angled scalene in which the hypotenuse is double the shortest side, Timaeus constructs four of the regular solids, cube, tetrahedron, octahedron, icosahedron, and these are assumed to be the shapes of the corpuses of earth, fire, air, water. These four in their turn are the immediate constituents of all organic and inorganic compounds.

The important features of the dialogue are not the particular tentative scientific hypotheses but its leading methodological principles. We should note the introduction of God as the intelligent efficient cause of all order and structure in the world of becoming, which preludes to the natural theology of the *Laws*, and the emphatic recognition of the essentially tentative and therefore progressive, character of natural science. It is also noticeable that though Plato's scientific ideal is a mathematical corporeal physics—his influence in creating this ideal has been much more important than that of the ancient atomists—he constructs his physical world without matter as a metaphysical substrate. The place of matter is taken in his analysis, as Aristotle complained, by *chora*, space, as in the *Principia* of Descartes, a point of view to which physical speculation seems to be returning. He analyzes the passage of nature into three factors: being (a form), space and happening (genesis) much as A. N. Whitehead analyzes it into objects, events and the ingredients of object into event.

It is a fundamental point that the presence of space as a factor makes it necessary to recognize over and above God or mind a subordinate element of *ananke*, "necessity," in events. Since necessity is also called the errant cause, *planomene aitia* (with an allusion to the name of the planets or tramp-stars) the word clearly does not mean conformity to law. It is rather a name for the fact that there is always in the actual an irreducible remainder of brute datum, "conjunctions" in Hume's phrase, which we cannot rationalize completely into intelligible connections. Thus *ananke* is not a rebel or evil principle in the constitution of things; its function is everywhere to be instrumental to the intelligent and beneficent purpose of mind or God. There are many facts which we have to be content to accept simply as facts without seeing their reason why. We do not know and may never know, why it is "best" that they should be as they are (e.g., why it is "best" that we should live on a moving earth) but we may be sure that, since it is the fact, it is in some way best that it should be so. This seems to be what is meant by the statement that God or mind (*nous*) persuades *ananke*. It is the expression of a rational faith in Providence and the supremacy of the moral order. The details of the cosmology, physiology and psychophysics of the dialogue are of great importance for the history of science, but metaphysically of secondary interest.

Laws and Epinomis.—The *Laws*, Plato's longest, is also his most intensely practical work and contains his ripest utterances on ethics, education and jurisprudence, as well as his one entirely nonmythical exposition of theology. The immediate object is to meet a practical need by providing a model of constitution making and legislation for members of the Academy who may be called on to assist his advisers in the actual founding or refounding of cities.

Plato's attempt to do work of this kind himself at Syracuse had borne no immediate fruit but had given the Academy a recognized standing as a school of scientific politics and jurisprudence. The work of constitution making and legislation was going on in many quarters at the end of his life, and his experience might be made fruitful in sage counsels to younger men. The practical character of the subject explains some novelties in the outward form of the work. As the dialogue is assumed to be dealing with the actual present, Socrates has disappeared and his place is taken by an unnamed Athenian who is, to all intents, Plato himself.

The scene is laid in Crete; the imagined situation is that the Cretans are about to found a settlement on the site of a long deserted city. The chief commissioner for the project is walking out to inspect the proposed site with a Spartan friend, when they meet the Athenian and, being favourably impressed by his conversation invite him to join them as an expert adviser.

The problem thus differs from that of the *Republic*; the question is not the construction of an ideal state, but the framing of a constitution and code which might be successfully adopted

by a society of average Greeks in the middle of the 4th century. Hence the demands made on average human nature, though exacting, are not pitched too high; the communism of the *Republic* is dropped. And for the same reason it is assumed all through that the regulations are carefully adapted to the particular economic and geographical conditions, though it is said that these conditions will not really suit any actual Cretan locality. If so, we must suppose that Plato, under a transparent disguise, is contemplating the actual conditions in quarters from which the Academy was more likely to receive appeals for help.

The special purpose of the work also explains why purely speculative philosophy and science are excluded from its purview. The metaphysical interest is introduced only so far as to provide a basis for a moral theology; the one matter of first-rate scientific importance touched on is the diurnal motion of the earth, and this is only hinted in connection with the practical problem of the construction of the calendar. In compensation, the *Laws* is exceptionally rich in political and juristic wisdom and appears, indirectly, through its influence on the law of the Hellenistic age, to have left its mark on the great system of Roman jurisprudence.

It is impossible to do more than to call attention to a few of the striking features of this great work. The ethical ideal is still that familiar from earlier dialogues. It is interesting that the demand is expressly made that all unnatural vices shall be completely suppressed and that the rule of sexual life is to be monogamous marriage with strict chastity, outside the limits of marriage, for both sexes. In politics, Plato declares himself definitely in favour of a mixed constitution; a good government demands a balance between two principles, *eleutheria*, "popular control," and *monarchia*, "personal authority." Persia is an illustration of the mischief of unqualified autocracy, Athens of the evils which come from elimination of the authoritarian principle, and considerable care is taken in the suggested system of magistracies to secure both genuine popular representation and the proper regard for personal qualifications. The basis of society is to be agriculture, not commerce; the citizens are to be peasant proprietors—communism is regretfully abandoned as impracticable in a society of ordinary human beings. But the patrimony of each household is to be strictly inalienable, and differences in personal property are to be kept within strict bounds by what amounts to a supertax of 100% on incomes beyond the statutory limits. Education, as in the *Republic*, is regarded as the most important of all the functions of government; it is placed under the control of a minister who is the premier. As far as possible, the distinction between the sexes is, as in the *Republic*, to be treated as irrelevant to the educational program.

The most striking features of the scheme are the careful attention paid to the problems of the physical training of children in their earliest infancy and to the right utilization of the child's instinct for play and the demand, made now for the first time, that in adolescence, the young shall be taught in institutions where expert instruction in all the various subjects is co-ordinated. It is from this proposal that the grammar school, or secondary school, has taken its origin. Though we hear no more of philosopher-kings the demand is still made that the members of the "nocturnal council," the supreme council of the state, which is always in permanent session, and exercises a general control over administration, shall be thoroughly trained, not only in the exact sciences, but in the supreme science, which "sees the one in the many and the many in the one"; that is, they are to be dialecticians.

The work is full of suggestions for the practical application of science, such, for example, as that of the necessity of strictly standardizing all weights and measures, or that of basing the calendar on a solar year (of 365 days). The object of the apparently arbitrary selection of the number of patrimonies and the scheme of subdivision of the whole society into smaller groups appears to be the practical one of making it easy to determine exactly what quorum each subdivision may justly be called on to contribute to the revenue or the defenses.

At least two fundamental improvements are made on the Attic

jurisprudence which Plato has adopted as the foundation of his own code. One great blot on the heliastic system is removed by the regulations which ensure that trials for serious offenses shall take place before a court which contains highly qualified magistrates, and shall proceed with due deliberation and that there shall be provision for appeals from the primary tribunal to a court of cassation. It is even more important, perhaps, that *Laws ix* by drawing a clear distinction between *blabe*, "detriment," and *adikia*, "infringement," of rights, lays the foundation for the discrimination between civil and criminal actions at law.

An incidental passage in the *Laws* (822 a-b) and another in the *Epinomis* (987 b) definitely show that Theophrastus was right in crediting Plato with belief in the earth's motion. In the *Laws* it is said that the real orbit of each planet is a single closed curve, in the *Epinomis* the view that the circle of the stars communicates its motion to those of the planets is called that of men "who know but little of the subject." The allusion is to the famous theory of the celestial motions put forward by Plato's friend and associate, the great mathematician Eudoxus.

According to this, the first great geocentric theory in scientific astronomy, the movements of each planet can be analyzed into a combination of circular revolutions; the unmoved earth being taken as the common centre of all. What Plato asserts is that each planet has only one proper revolution, the remaining revolutions are apparent, not real. The implication is that these apparent revolutions of the planet must be real motions of the earth from which we make our observations. The earth is thus a planet, though not a satellite of the sun. The language of the *Epinomis*—which may be safely regarded as at least true to Plato's thought—definitely makes the sun, itself, one of the planets. We have, therefore, to think of the earth as also a planet revolving with the rest round an unseen centre. We may infer from the words of Theophrastus that Plato, like some of the Pythagoreans, held that there is a luminary, the "central fire," at this centre. The period of the earth's revolution would certainly be taken to be the natural day, so that the motion ascribed to the earth is equivalent to the diurnal rotation, though from Plato's point of view it is not a rotation on an axis, but a revolution round a centre. It follows that the alternation of day and night is no longer accounted for by a rotation of the heaven of the fixed stars. This outermost circle is still credited in the *Epinomis* with a revolution in the sense east to west, but its period is not specified. We need not suppose either that Plato could have specified the period or that he used it to explain any special appearances. It has nothing to do with precession of the equinoxes, being in the wrong sense for that purpose.

What is to Plato's credit is that he has the insight to see that, with all its attractions, the scheme of Eudoxus starts from a wrong presupposition, a stationary earth.

In *Laws x* Plato, for a practical purpose, creates natural theology. There are three false beliefs which are fatal to moral character, atheism, denial of the moral government of the world, the belief that divine judgment can be bought off by offerings. Plato holds that he can disprove them all. The refutation of atheism turns on the identification of the soul with the "movement which can move itself," already used in the *Phaedrus*. All motion is either communicated from without or self-initiated, and the ultimate source of all communicated motion must be self-initiated motion. The only thing which can move itself is a soul. It follows that all motion throughout the universe is ultimately initiated by souls. It is then inferred from the regular character of the great cosmic motions and their systematic unity, that the souls which originate them form a hierarchy with a best soul, God, at their head. Disorderly and irregular motions are equally due to souls, but to bad and disordered souls, and from the fact that there are disorderly motions, it is inferred that the best soul cannot be the only soul.

There is no suggestion that there is a worst soul, a devil or evil world-soul; all that is said is that there must be one soul which is not the best, and may be more. This is Plato's way of excluding pantheism, as incompatible with the reality of evil. The argument thus establishes at once the immortality of the soul

and the existence of God. The other two heresies can now be disposed of. It is inconsistent with the goodness of the best soul to be indifferent to our conduct, and still more so to be venal. The moral government of the world is, in fact, assured by the establishment of the single principle that every soul gravitates into the society of its desires and consequently does and has done to it what it befits such a soul to do and have done to it. Plato thus becomes the originator of the view that there are certain theological truths which can be strictly demonstrated by reason.

It is these demonstrable truths which are subsequently named by M. Terentius Varro natural or philosophical theology in contradistinction to the poetical theology, the myths related by the poets, and the civil theology, the ritual cultus instituted by politicians. From Varro the distinction of three theologies passed to St. Augustine and thus in the end became the foundation of the scholastic distinction between natural theology, those truths about God which can be ascertained independently of any specific revelation, and revealed theology, the further truths which are only made accessible by the Christian revelation. Since Plato's object in demonstrating his three propositions is an ethical one, he goes on to enact that the denial of any of them shall be a grave crime to be visited by the state with penalties ranging from a minimum of five years' solitary confinement, and with death on a second conviction. Plato is thus the inventor, so far as European society is concerned, of the proposal to make an official creed for the state and to treat dissent from it as criminal, an innovation foreign to the spirit of the Hellenic cities, in which religion was a matter not of beliefs but of cultures. Plato's last word, then, on the problem how the sensible comes to partake of form is that it does so through the agency of divine goodness and wisdom. God molds the sensible upon the pattern of the intelligible. The obvious question, how God, who is a soul not a form, is related to the good which is the supreme form never receives discussion or solution. To answer that question was to be the main business of Plotinus.

PLATONISM AFTER PLATO

Aristotle's Account of Platonism.—Since Plato refused to write any formal exposition of his own metaphysic, our knowledge of its final shape has to be derived from the statements of Aristotle, which are confirmed by scanty remains of the earliest Platonists preserved in the Neoplatonist commentaries on Aristotle. These statements can, unfortunately, only be interpreted conjecturally. According to Aristotle (*Metaphysics i*, 987 b 18-25) Plato's doctrine of forms was, in its general character, not different from Pythagoreanism, the forms being actually called numbers. The two points on which Aristotle regards Plato as disagreeing with the Pythagoreans are (1) that whereas the Pythagoreans said that numbers have as their constituents, the unlimited and the limit, Plato taught that the forms have as constituents the one and the great and small; and (2) that whereas the Pythagoreans had said that things are numbers, Plato intercalated between his forms (or numbers) and sensible things an intermediate class of mathematical. It is curious, that in connection with the former difference Aristotle dwells mainly on the substitution of the "duality of the great and small" for the "unlimited," not on the much more significant point that the one, which the Pythagoreans regarded as the simplest complex of unlimited and limit, is treated by Plato as itself the element of limit. He further adds that the "great and small" is, in his own technical terminology, the matter, the one, the formal constituent, in a number.

If we could be sure how much of the polemic against number-forms in *Metaphysics xiii-xiv* is aimed directly at Plato, we might add considerably to this bald statement of his doctrine, but unluckily it is certain that much of the polemic is concerned with the teaching of Speusippus and Xenocrates. It is not safe, therefore, to ascribe to Plato statements other than those with which Aristotle explicitly credits him. We have then to interpret, if we can, two main statements: (1) the statement that the forms are numbers; (2) the statement that the constituents of a number are the great and small and the one.

Light is thrown on the first statement if we recall the corpuscular physics of the *Timaeus* and the mixture of the *Philebus*. In the *Timaeus*, in particular, the behaviour of bodies is explained by the geometrical structure of their corpuscles, and the corpuscles themselves are analyzed into complexes built up out of two types of elementary triangle, which are the simplest elements of the narrative of *Timaeus*. Now a triangle, being determined in everything but absolute magnitude by the numbers which express the ratio of its sides, may be regarded as a triplet of numbers. If we remember then, that the triangles determine the character of bodies and are, themselves, determined by numbers, we may see why the ultimate forms on which the character of nature depends should be said to be numbers, and also what is meant by the mathematical intermediate between the forms and sensible things. According to Aristotle, these mathematical differ from forms because they are many, whereas the form is one, from sensible things in being unchanging. This is exactly how the geometer's figure differs at once from the type it embodies and from a visible thing. There is, for example, only one type of triangle whose sides have the ratios 3:4:5, but there may be as many pure instances of the type as there are triplets of numbers exhibiting these ratios; and again, the geometrical triangles which are such pure instances of the type, unlike sensible three-sided figures, embody the type exactly and unchangingly. A mathematical physicist may thus readily be led to what seems to be Plato's view that the relations of numbers are the key to the whole mystery of nature, as is actually said in the *Epinomis* (990 e).

We can now, perhaps, see the motive for the further departure from Pythagoreanism. It is clear that the Pythagorean parallelism between geometry and arithmetic rested upon the thought that the point is to spatial magnitude what the number 1 is to number. Numbers were thought of as collections of units, and volumes, in like fashion, as collections of points; that is, the point was conceived as a minimum volume. As the criticisms of Zeno showed, this conception was fatal to the specially Pythagorean science of geometry itself, since it makes it impossible to assert the continuity of spatial magnitude. (This, no doubt, is why Plato, as Aristotle tells us, rejected the notion of a point as a fiction.)

There is also a difficulty about the notion of a number as a collection of units, which must have been forced on Plato's attention by the interest in irrationals which is shown by repeated allusions in the dialogues, as well as by the later anecdotes which represent him as busied with the problem of doubling the cube or finding two mean proportionals. Irrational square and cube roots cannot possibly be reached by any process of forming collections of units, and yet it is a problem in mathematics to determine them, and their determination is required for physics (*Epinomis* 990 c-991 b).

This is sufficient to explain why it is necessary to regard the numbers which are the physicist's determinants as themselves terminations of a continuum (a great and small), by a limit and why, at the same time the one can no longer be regarded as a blend of unlimited and limit but must be, itself, the factor of limit. (If it were the first result of the blending, it would reappear in all the further blends; all numbers would be collections of one and there would be no place for the irrationals.) There is no doubt that Plato's thought proceeded on these general lines. Aristotle tells us that he said that numbers are not really addible (*Metaphysics* xiii, 1083 a.34), that is, that the integer series is not really made by successive additions of 1; and the *Epinomis* is emphatic on the point that contrary to the accepted opinion, surds are just as much numbers as integers. The underlying thought is that numbers are to be thought of as generated in a way which will permit the inclusion of rationals and irrationals in the same series. In point of fact there are logical difficulties which make it impossible to solve the problem precisely on these lines. It is true that mathematics requires a sound logical theory of irrational numbers and, again, that an integer is not a collection of units; it is not true that rational integers and real numbers form a single series.

The Platonic number theory was inspired by thoughts which have since borne fruit abundantly but was itself premature. We learn partly from Aristotle, partly from notices preserved by his commentators, that in the derivation of the integer series, the even numbers were supposed to be generated by the dyad which doubles whatever it lays hold of, the odd numbers in some way by the one which limits or equalizes, but the interpretation of these statements is, at best, conjectural. In the statement about the dyad there seems to be some confusion between the number 2 and the indeterminate dyad, another name for the continuum also called the great and small, and it is not clear whether this confusion was inherent in the theory itself, or has been caused by Aristotle's misapprehension.

Nor, again, is it at all certain exactly what is meant by the operation of equalizing ascribed to the one. It would be improper here to propound conjectures which our space will not allow us to discuss. A collection and examination of the available evidence is given by L. Robin in his *Théorie platonicienne des idées et des nombres d'après Aristote* (1908), and an admirable exposition of the significance of the problem of the irrational for Plato's philosophy by G. Milhaud in *Les Philosophes-géomètres de la Grèce, Platon et ses prédécesseurs*, new ed. (1934). For a conjectural interpretation see A. E. Taylor, "Forms and Numbers," in *Mind*, new series, 140, 141.

The Academy After Plato.—Plato's Academy continued to exist as a corporate body down to A.D. 529 when the emperor Justinian, in his zeal for Christian orthodoxy, closed the schools of Athens and appropriated their emoluments (see ACADEMY, GREEK). Plato's greatest scholar, Aristotle, had finally gone his own way and organized a school of his own in the Lyceum, claiming that he was preserving the essential spirit of Platonism, while rejecting the difficult doctrine of the forms. The place of official head of the Academy was filled first by Speusippus, Plato's nephew (c. 347-339 B.C.), then by Xenocrates (c. 339-314 B.C.). Under Arcesilaus (c. 276-241 B.C.) the Academy began its long-continued polemic against the sensationalist dogmatism of the Stoics, which accounts both for the tradition of later antiquity which dates the rise of a New (some said Middle) and purely skeptical Academy from Arcesilaus and for the 18th-century associations of the phrase "academic philosophy."

In the 1st century B.C. the most interesting episode in the history of the school is the quarrel between its president Philo of Larissa and his scholar Antiochus of Ascalon, of which Cicero's *Academica* is the literary record. Antiochus, who had embraced Stoic tenets, alleged that Plato had really held views indistinguishable from those of Zeno of Citium and that Arcesilaus had corrupted the doctrine of the Academy in a skeptical sense. Philo denied this. The gradual *rapprochement* between Stoicism and the Academy is illustrated from the other side by the work of Stoic scholars such as Panaetius of Rhodes and Poseidonius of Apamea, who commented on Platonic dialogues and modified the doctrines of their school in a Platonic sense.

The history of the Academy after Philo is obscure, but since the late 1st century A.D. we meet with a popular literary Platonism of which the writings of Plutarch are the best example. This popular Platonism insists on the value of religion, in opposition to Epicureanism, and on the freedom of the will and the reality of human initiative, in opposition to the Stoic determinism; a further characteristic feature, wholly incompatible with the genuine doctrine of Plato, is the notion that matter is inherently evil and the source of moral evil.

Genuine Platonism was revived in the 3rd century A.D., in Rome, and independently of the Academy, by Plotinus. His Neoplatonism (q.v.) represents a real effort to do justice to the whole thought of Plato. Two aspects of Plato's thought, however, in the changed conditions inevitably fell into the background, the mathematical physics and the politics. The 3rd century A.D. had no understanding for the former, and the Roman empire under a succession of military chiefs no place for the latter. The doctrine of Plotinus is Platonism seen through the personal temperament of a saintly mystic, and with the *Symposium* and the teaching of the *Republic* about the form of good always in the foreground.

Plotinus lived in an atmosphere too pure for sectarian polemic, but in the hands of his successors, Neoplatonism was developed in conscious opposition to Christianity. Porphyry, his disciple and biographer, was the most formidable of the anti-Christian controversialists; in the next century, "Platonists" were among the allies and counsellors of the emperor Julian in his attempts to invent an Hellenic counterpart to Christianity.

Early in the 5th century, Neoplatonism flourished for a short time in Alexandria (which disgraced itself by the murder of Hypatia in 415) and captured the Athenian Academy itself, where its last great representative was the acute Proclus (A.D. 410-485). The latest members of the Academy, under Justinian, occupied themselves chiefly with learned commentaries on Aristotle, of which those of Simplicius are the most valuable. The doctrine of the school itself ends in Damascius with mystical agnosticism.

Influence on Christian Thought.—Traces of Plato are probably to be detected in the Alexandrian *Wisdom of Solomon*; the thought of the Alexandrian Jewish philosopher and theologian Philo, in the 1st century A.D., is at least as much Platonic as Stoic. There are, perhaps, no certain marks of Platonic influence in the New Testament, but the earliest apologists (Justin, Athenagoras) appealed to the witness of Plato against the puerilities and indecencies of mythology. In the 3rd century Clement of Alexandria and after him Origen made Platonism the metaphysical foundation of what was intended to be a definitely Christian philosophy. The church could not, in the end, conciliate Platonist eschatology with the dogmas of the resurrection of the flesh and the final judgment, but in a less extreme form the platonizing tendency was continued in the next century by the Cappadocians, notably St. Gregory Nyssa, and passed from them to St. Ambrose of Milan. The main sources of the Platonism which dominated the philosophy of western Christian theologians through the earlier middle ages, were, however, Augustine, the greatest thinker among the western fathers, who had been profoundly influenced by Plotinus read in a Latin version, before his conversion to Christianity; and Boëthius, whose wholly Platonist vindication of the ways of Providence in his *De Consolatione Philosophiae* was the favourite serious book of the middle ages.

A further powerful influence was exerted by the writings of the so-called Dionysius the Areopagite (q.v.), which laid down the main lines of medieval mystical theology and angelology. These works are, in fact, an imperfectly Christianized version of the speculations of Proclus and cannot date before the end of the 5th century A.D. at the earliest, but they enjoyed an immense authority based on their attribution to an immediate convert of St. Paul. After their translation into Latin in the 9th century by Johannes Scotus Erigena, they became popular in the west.

Apart from this theological influence, Plato dominated the thought of the earlier Renaissance which dates from the time of Charlemagne in another way. Since the west possessed the philosophical writings of Cicero, with the Neoplatonic comment of Macrobius on the *Somnium Scipionis*, as well as the Latin translation of the first two-thirds of the *Timaeus* by Chalcidius, with his commentary on the text, and versions, also, at least of the *Phaedo* and of the *Meno*, whereas nothing was known of the works of Aristotle except Latin versions of some of the logical treatises, the middle age, between Charlemagne and the beginning of the 13th century, when the recovery of Aristotle's physics and metaphysics from Moors, Persians and Jews began, was much better informed about Plato than about Aristotle; in particular, in the various encyclopaedias of this period, it is the *Timaeus* which forms the regular background.

The 13th century saw a change. Aristotle came to displace Plato as the philosopher, partly in consequence of the immediately perceived value of his strictly scientific works as a storehouse of well-digested natural facts, partly from the brilliant success of the enterprise carried through by St. Thomas Aquinas, the reconstruction of philosophical theology on an Aristotelian basis. Plato is, however, by no means supplanted in the Thomist system; the impress of Augustine on western thought has been far too deep for that. Augustine's "exemplarism," that is, the doctrine of forms in the version, ultimately derived from Philo of Alex-

andria, which makes the forms creative thoughts of God, is an integral part of the Thomist metaphysics, though it is now denied that the exemplars are themselves cognizable by the human intellect, which has to collect its forms, as best it can, from the data of sense.

Directly or through Augustine, the influence of Plato, not only on strictly philosophic thought but on popular ethics and religion, has repeatedly come to the front in ages of general spiritual quickening and shows no signs of being on the wane.

Two revivals in particular are famous. The first is that of the 16th century, marked by the Latin translation of Marsilio Ficino and the foundation of Lorenzo de' Medici's fantastic Florentine Academy. What was revived then was not so much the spirit of Plato as that of the least sober of the Neoplatonists; the influence of the revival was felt more in literature than in philosophy or morals, but in literature its importance may be measured by the mere mention of such names as Michelangelo, Sir Philip Sidney and Edmund Spenser.

In the 17th century, Plato, seen chiefly through the medium of Plotinus, supplied the inspiration of a group of noble thinkers who were vindicating a more inward morality and religion against the unspiritual secularism and Erastianism of Hobbes: namely the so-called Cambridge Platonists (q.v.), Benjamin Whichcote, Henry More, Ralph Cudworth and John Smith. In the 20th century, on the one hand A. N. Whitehead tried to work out a philosophy of the sciences which confessedly connected itself with the ideas of the *Timaeus*; and on the other the rise of totalitarian governments produced a number of publications confronting Plato with the theories (Communist, Fascist, etc.) inherent in their policies.

See also references under "Plato" in the Index.

BIBLIOGRAPHY.—The works of Plato are conveniently arranged in nine tetralogies as follows: (1) *Euthyphro*, *Apology*, *Crito*, *Phaedo*; (2) *Cratylus*, *Theaetetus*, *Sophistes*, *Politicus*; (3) *Parmenides*, *Philebus*, *Symposium*, *Phaedrus*; (4) *Alcibiades I*, *Alcibiades II*, *Hipparchus*, *Erastae*; (5) *Theages*, *Charmides*, *Laches*, *Lysis*; (6) *Euthydemus*, *Protagoras*, *Gorgias*, *Meno*; (7) *Hippias I (major)*, *Hippias II (minor)*, *Ion*, *Menexenus*; (8) *Clitophon*, *Republic*, *Timaeus*, *Critias*; and (9) *Minos*, *Laws*, *Epinomis*, *Epistles*. Of the manuscript codices, none of which are earlier than the 9th century A.D., the most important are the Bodleianus-Clarkianus (containing the first six tetralogies), the Parisinus 1807 A (containing the eighth and the ninth) and the Venetus (containing the first seven and part of the eighth). Since the end of the 19th century papyrus fragments have been found; on these, see H. Leisegang, "Platon" (1950), in Pauly-Wissowa, *Real-Encyclopädie der Classischen Altertumswissenschaft*. On the text and the canon see: H. Aline, *Histoire du texte de Platon* (1915); L. A. Post, *The Vatican Plato and Its Relations* (1935); G. Jachmann, "Der Platontext" in *Nachrichten der Akademie der Wissenschaften in Göttingen, Phil.-hist. Klasse* 1941 (1942); E. Bickel, "Das Platonische Schriftenkorpus . . ." and "Geschichte und Recensio des Platontextes," in *Rheinisches Museum*, 92 (1943).

Modern editions of Plato refer to the pagination of the edition by (J. Serranus and) H. Stephanus, 3 vol., with Lat. trans. (1578), which is used also in the foregoing text of this article. The standard edition is that by J. Burnet, 5 vol. (1899-1907), containing not only all the 36 works of the nine tetralogies but also the *spuria* (*Definitions*, *On Justice*, *On Virtue*, *Demodocus*, *Sisyphus*, *Halcyon*, *Eryxias* and *Axiarchus*). Earlier editions deserving mention are those of G. Stallbaum, 12 vol. (1827-42), improved edition with extensive commentary in Latin; and of K. F. Hermann, 6 vol. (1851-53), rev. by M. Wohlrab (1884-87), containing not only Plato's works and the *spuria* but also the Pseudo-Timaeus *Locus On the World Soul*, two writings by Albinus, the biography by Olympiodorus, the scholia, an index of names, etc. There is a collected edition in Greek and English by W. R. M. Lamb, H. N. Fowler et al. (1914 et seq.); and another in Greek and French by A. Croiset et al. (1920 et seq.). The Eng. trans. by B. Jowett, 4th ed., rev. by D. J. Allan and H. E. Dale (1953), omits *Alcibiades II*, *Hipparchus*, *Erastae*, *Theages*, *Clitophon*, *Minos*, *Epinomis* and *Epistles*. Among translations into other languages are those into German by H. Müller, 8 vol. (1850-66) and by O. Apelt, 25 vol. (1912-22; with rich bibliographies and index); into French by L. Robin and J. Moreau, 2 vol. (1940 et seq.); and into Italian by E. Turolla, 3 vol. (1953).

For individual works, the following editions, annotated translations and commentaries may be recommended: *Hippias I*, ed. by D. Tarrant (1928); *Ion*, ed. by St. G. Stock (1909); *Menexenus*, ed. by J. A. Shawyer (1906); *Laches*, ed. by G. Ammendola (1933); *Euthydemus*, ed. by E. H. Gifford (1905); *Gorgias*, ed. by W. H. Thompson (1894); *Meno*, 3rd ed. by St. G. Stock, 2 parts (1955); *Protagoras*, ed. by J. Adam (1893; reissue 1940) and 7th ed. by W. Nestle (1931); *Euthyphro*, *Apology* and *Crito* (1924) and *Phaedo* (1911),

both ed. by J. Burnet, as well as *Apology*, ed. by J. Riddell (1867) and *Phaedo*, trans. by R. S. Bluck (1955) and by R. Hackforth (1955); *Symposium*, 2nd ed. by R. G. Bury (1932); *Phaedrus*, trans. by R. Hackforth (1952) and by J. B. Skemp (1952); *Republic*, ed. by J. Adam, vol. i, 4th ed. (1926), vol. ii, 3rd ed. (1921) and trans. by F. M. Cornford (1941); *Parmenides*, trans. by F. M. Cornford, *Plato and Parmenides* (1939; reprinted, 1950); *Theaetetus* and *Sophistes*, trans. by F. M. Cornford, *Plato's Theory of Knowledge* (1935; 1957); *Theaetetus*, 2nd ed. by L. Campbell (1883); *Politicus*, trans. by J. B. Skemp, *Plato's Statesman* (1952; new ed., 1957); *Philebus*, ed. by R. B. Bury (1897) and trans. by R. Hackforth, *Plato's Examination of Pleasure* (1945); *Timaeus*, ed. and trans. by R. Archer-Hind (1888) and trans. by F. M. Cornford, *Plato's Cosmology* (1937; reprinted 1957), commentary by A. E. Taylor (1928); *Laws*, commentary by C. Ritter (1896) and ed. by E. B. England, 2 vol. (1921); *Epinomis*, trans. by J. Harward (1928); with *Philebus*, trans. by A. E. Taylor (1956); *Epistles*, ed. by G. Pasquali (1938) and by A. Maddalena (1948) and trans. by L. A. Post (1925), by J. Harward (1932) and by G. R. Morrow (1935). The standard edition of the *Scholion Platonicum* is ed. by W. C. Greene et al. (1939). See also A. Diès, *Autour de Platon: essais de critique et d'histoire*, 2 vol. (1927); R. Schaefer, *La Question platonicienne* (1938); M. Pohlenz, *Aus Platos Werdezeit* (1913); H. Armin, *Platons Jugenddialogue und die Entstehungszeit des Phaidros* (1914); and R. Hackforth, *The Composition of Plato's Apology* (1933).

Comprehensive presentations are to be found in J. Burnet, *Greek Philosophy*, part 1 (1914); in E. Zeller, *Die Philosophie der Griechen*, vol. ii, part 2, 4th ed. (1921); in T. PLATO (fl. c. 400 B.C.), Greek poet, was a writer of Old Comedy. His earliest play was probably produced in 427 B.C., his last in 387. Of his 28 comedies most were on political themes. He attacked Hyperbolus in his *Periarges* ("The Sufferer"; 420?), Diotrephes in the *Heortai* ("The Festivals"; 414?) and Peisander and Cleophon in the so-named plays. Mythological burlesques are represented by such plays as the *Adonis*, the *Daidalos*, the *Phaon*, etc., and social (= Middle) comedy by the *Sophistai*, for example.

Antiquity admired the elegance of his style.

PLATONIC LOVE, a locution used in two senses, with allusion in both cases to Plato's account of love in his *Symposium* (see *PLATO: The Earlier Dialogues*).

1. In common speech, platonic love means a supremely affectionate relationship between human beings in which sexual intercourse is neither desired nor practised. In this sense, it most often refers to a heterosexual relationship. By extension, it may be used to cover that stage of chivalrous or courtly love in which sexual intercourse is indefinitely postponed.

2. From the Renaissance to the end of the 19th century platonic love was used as an occasional euphemism for homosexual love, in view of the comparatively tolerant attitude to such love discernible in Plato as well as in other Greek authors.

PLATOON, the principal subdivision of a military company (*q.v.*), battery, or troop. Customarily commanded by a lieutenant, it consists of from 25 to 50 men organized into two or more sections or squads led by noncommissioned officers.

In the 17th century the term referred to a small body of musketeers who fired together in a volley, alternately with another platoon, and it has always retained some sense of systematic alternate employment. Hence "platoon fire" meant a regulated fire of alternating platoon volleys, and "platoon" sometimes referred to the volley itself. In the 18th century battalions were often organized for tactical purposes into 16 platoons of about 24 men each, plus 2 or 4 platoons of grenadiers or light infantry.

The term "platoon" has been used in U.S. military manuals since 1779 and throughout the 19th century meant half a company. The platoon was reintroduced into the British Army in 1913.

The "platoon system" in municipal police and U.S. football organizations signifies the use of two or more shifts or teams of comparable strength that alternate on duty. (F. P. T.)

PLATT, THOMAS COLLIER (1833-1910), U.S. senator and for a time the political boss of New York State, was born in Owego, N.Y., July 15, 1833. Educated in Owego and at Yale College, he entered banking and later became secretary and then president of the United States Express Company. After serving as chairman of the Tioga County Republican Committee in the 1860s, Platt was elected in 1873 to the U.S. House of Representatives, where he served until 1877. He had meanwhile become a political ally of Sen. Roscoe Conkling and in January 1881 was himself elected to the U.S. Senate. Because of a quarrel with Pres. James Garfield over patronage, both Platt and Conkling resigned from the Senate in May 1881.

After Conkling's retirement from politics, Platt gained control of the Republican Party in New York State. He remained prominent in the Republican Party for a number of years and attended every national convention of the party from 1876 to 1904. He helped obtain the declaration for the gold standard at the 1896 convention.

He reluctantly gave his support to the campaign of Theodore Roosevelt for governor of New York and later for vice-president of the United States. Platt served in the U.S. Senate again from 1897 to 1909, but his political power waned steadily after 1903. He died in New York City, March 6, 1910. (Rt. W. C.)

PLATT AMENDMENT, an amendment to the U.S. army appropriation bill of March 1901, offered by Sen. Orville H. Platt of Connecticut and adopted by congress, which defined the conditions on which the United States was willing to end the military occupation of Cuba that had followed the Spanish-American War of 1898. Elihu Root, secretary of war, had previously formulated the terms on which the United States would withdraw and leave the government of Cuba to the Cubans. It was the Root formulation that Platt offered in the senate, with the proviso that the conditions must be embodied in the new Cuban constitution and also in a permanent treaty with the United States. The Cuban Constitutional convention reluctantly accepted the amendment. In so doing, it agreed that Cuba would validate the acts, and carry out the sanitary program, of the U.S. military government; that it would not impair Cuban independence by treaty with, or cession of territory to, any "foreign" power, or contract any debt beyond the capacity of the ordinary revenues to pay. It conceded to the United States the right to a naval base in Cuban territory and waters (later fixed at Guantánamo bay) and gave the United States the right to intervene in Cuba for the preservation of orderly government or of Cuban independence—a right the United States exercised repeatedly during the next 30 years. The Cubans never liked the Platt amendment, for they regarded it as an infringement of their sovereignty. In 1934 the United States negotiated a new treaty with Cuba that abrogated all provisions of the Platt amendment except the right to the naval base at Guantánamo bay.

PLATTE, a river system of the western United States, tributary to the Missouri river. The Platte river, 310 mi. long, is formed at North Platte, Neb., where the North Platte, 618 mi. long, and the South Platte, 424 mi. long, flow together. The North Platte river rises in the Medicine Bow and Park ranges and the Rabbit Ears mountains of north-central Colorado. It flows north into Wyoming and bends east-southeast at Casper, Wyo., flowing into western Nebraska. In eastern Wyoming the North Platte valley is one to ten miles wide and from 100 to 300 ft. below the surrounding uplands. On the Wyoming-Nebraska boundary the North Platte flows through the Goshen Hole where the valley has widened to 50 mi. in places and the bordering bluffs are 400 ft. high. Torrington, Wyo., and Scottsbluff, Neb., mark the western and eastern extremities of the Goshen Hole. On the North Platte there are three large reservoirs used for irrigation and power: Pathfinder reservoir near Alcova, Wyo., completed in April 1909, with storage capacity of 1,010,900 ac.ft.; Seminole reservoir near Leo, Wyo., completed in March 1939, capacity 1,012,000 ac.ft. and Alcova reservoir at Alcova completed in Jan. 1938, capacity 190,500 ac.ft.

The South Platte river rises in Park county on the Mosquito range of central Colorado and flows southeast across South Park. West of Divide, Colo., the river turns sharply northeast, flows through the Front range via the Platte River canyon and emerges on the flat land of the Colorado piedmont southeast of Denver. Continuing its northeast course, it flows through Denver to Greeley, Colo., where it bends eastward to North Platte. From Greeley east the valley of the South Platte is from two to ten miles wide. The river bed is filled with sandbars and the stream channel is often braided. Cheesman, Eleven Mile Canyon, and Antero reservoirs on the upper South Platte are storage units for Denver's water supply.

From North Platte the Platte river flows southeast into a big bend at Kearney, Neb., turns northeast and empties into the Missouri at Plattsmouth, Neb. During the spring runoff the Platte river is a mile wide in many places and almost dry the remainder of the year. Important tributaries of the North Platte

are the Sweetwater and Laramie rivers and Medicine Bow creek. South Platte tributaries are Clear creek and Boulder creek and the Big Thompson, St. Vrain and Cache La Poudre rivers. The Loup river is the largest tributary of the Platte. The vast quantities of water diverted for irrigation agriculture and for municipal use are the most significant aspects of the Platte river system.

(M. J. L.)

PLATTER, THOMAS (1499-1582), Swiss writer and humanist, best known for his autobiography, was born at Grächen, Valais, on Feb. 10, 1499, and died at Basel on Jan. 26, 1582. After years of hardship, spent as a goatherd in the Alps and as a "fag" to a traveling scholar in Germany, he was initiated at Zürich into Huldreich Zwingli's teachings and the newly discovered world of Greek, Latin and Hebrew culture by Oswald Myconius, the first biographer of the Swiss reformer. Moving to Basel, Platter first earned his living as a ropemaker but contributed to the renown of this great centre of humanistic learning by teaching Hebrew, working as partner to the printer, Andrew Cratander, and after 1541 reforming Basel grammar school. His autobiography, completed in 1576, is an interesting and important document of the period and tells the story of his lifelong struggle against heavy odds in self-education. The work of his son, FELIX (1536-1614), physician at Basel, anticipated modern psychopathology.

BIBLIOGRAPHY.—Platter's *Selbstbiographie* (with the *Tagebuch* of his son Felix), ed. by H. Boos, 2nd ed. (1918), Eng. trans. by E. A. McCaul Finn, 2nd ed. (1847); *Briefe an seinen Sohn Felix*, ed. by A. A. Burckhardt (1890). PLATTSBURGH, a city of Clinton county, N.Y., U.S., on the west shore of Lake Champlain. Plattsburgh is surrounded by beautiful scenery: the broad island-studded lake in front, the Green mountains beyond, and on the southern horizon the distant Adirondacks. Part of Plattsburgh air force base, serving the Strategic Air Command, is on the site of an army post established in 1815. An experimental businessmen's military training camp at this post in 1915 served as a prototype for reserve officer training facilities during World War I. After World War II the first university for U.S. veterans was established there and later disbanded. Located in the city is the State University College at Plattsburgh, which originated in 1889 as a normal and training school and which became a unit of the State University of New York in 1949. Plattsburgh is a recreational area and marketing and manufacturing centre of pulp, paper and allied products. The city was founded by Zephaniah Platt (1740-1807), who brought a colony from Long Island. Recognized as a town April 4, 1785, it was incorporated as a city in 1902. The opening naval engagement of the American Revolution (a victory for the British) took place at Valcour Island 5 mi. S.E. of Plattsburgh on Oct. 11, 1776. In the War of 1812 the city was the headquarters of the U.S. army on the northern frontier. In Sept. 1814 the village was besieged in what was planned to be a joint attack by sea and by land; on Sept. 11 Commodore Thomas Macdonough and the U.S. forces defeated the invading British fleet and the British army, deprived of naval support, retreated. See WAR OF 1812.

For comparative population figures see table in NEW YORK: Population. (G. L. F.)

PLATYHELMINTHES (PLATODARIA), a phylum of invertebrate animals, the flatworms, soft-bodied creatures that are bilaterally symmetrical and usually somewhat flattened in shape. The group includes both free-living (see FLATWORM) and parasitic (see FLUKE; TAPEWORM) species.

PLATYPUS (*Ornithorhynchus anatinus*), one of the most primitive of living mammals, composing with the echidnas (*q.v.*) or spiny anteaters the order Monotremata. Often referred to as the duck-billed platypus or duckbill because of its elongate, flattened, leathery bill-like muzzle, this species is confined to eastern Australia and Tasmania. Being a mammal, the platypus possesses hair and provides milk for its young. Like all monotremes, however, it differs from other mammals in laying eggs and lacking true nipples. The milk of lactating females exudes from the mammary glands and is lapped up by the young from the mother's abdominal fur. The adult male may be about two feet long, the

BY COURTESY OF AUSTRALIAN NEWS AND INFORMATION BUREAU

PLATYPUS (ORNITHORHYNCHUS ANATINUS), AN EGG-LAYING MAMMAL

female being smaller. A dense, gray-brown fur covers the body and the flattened beaverlike tail. Teeth are lacking in the adult. Both front and hind feet are webbed. The male possesses on the inside of each ankle a sharp, horny spur connected to a poison sac. These spurs are wielded with a slashing or stabbing motion. The wound, infiltrated with venom, is fatal in some small animals but merely painful in larger ones, including man.

The platypus is semiaquatic, living along the banks of rivers. Two types of burrows are constructed. One is used by both sexes outside of the breeding season and by bachelors during the latter period. The other is made by the female and contains a nest chamber in which she deposits and incubates her two white, soft-shelled, roundish eggs.

The food of the platypus consists principally of aquatic insects, worms, small crustaceans and mollusks. See also MONOTREME; MAMMAL. (R. T. O.)

PLAUVEN, a town of East Germany in the *Bezirk* (district) of Karl-Marx-Stadt, German Democratic Republic. It lies 90 km. (56 mi.) SW of Karl-Marx-Stadt (Chemnitz) by road. Pop. (1962 est.) 78,983. Situated on the slopes of the Weisse Elster valley, Plauen is the principal town in the scenically beautiful Vogtland. It was severely damaged by air raids in World War II. The old town hall (enlarged in 1508) is adjoined by the modern town hall; the 12th-century Johanneskirche was restored in the 19th century; the old castle is now a lawcourt. There is a textile craft school. Plauen is a junction on the Berlin-Leipzig-Hof-Munich railway. The town's best-known industry is lace making, but linen, cotton, and embroidered goods, curtains, printing presses, trucks, and machinery are among its many manufactures. In the Middle Ages Vogtland was directly administered by the Vogts or bailiffs, the term surviving in the name of the region. First mentioned in 1122, Plauen became the centre of a flourishing textile craft.

PLAUTUS (fl. late 3rd and probably early 2nd century B.C.) was the great comic dramatist of ancient Rome. Twenty-one plays (*Amphitruo*, *Asinaria*, *Aulularia*, *Bacchides*, *Captivi*, *Casina*, *Cistellaria*, *Curculio*, *Epidicus*, *Menaechmi*, *Mercator*, *Miles Gloriosus*, *Mostellaria*, *Persa*, *Poenulus*, *Pseudolus*, *Rudens*, *Stichus*, *Trinummus*, *Truculentus* and the fragmentary *Vidularia*) ascribed to Plautus have survived in the manuscripts (i.e., the 4th-century Ambrosian palimpsest, known as "A," and various manuscripts of the 10th century and later, known as the "Palatine" family). According to Festus and Jerome he was born at Sarsina, in Umbria; his death occurred in 184 B.C. according to Cicero; in 200, according to Jerome. The two *didascaliae* (notes in the form of a preface) preserved in "A" are usually regarded as firm evidence that the *Stichus* was produced in 200 and the *Pseudolus* in 191; but see H. B. Mattingly, "The Plautine 'Didascalae,'" *Athenaeum* (nuova serie), xxxv, pp. 78-88 (1957).

According to Cicero, Plautus in his old age took great pleasure in his *Pseudolus* and *Truculentus*. This may be invention, indicating merely that these were popular plays in Cicero's day; but on it is founded the usual view that Plautus was born about 250 B.C. The only extant record as to his life is that of Aulus Gellius (based on Varro), the historical character of which is questioned by Friedrich Leo in his *Plautinische Forschungen* (2nd ed.; 1912). It is probably invention or mistaken inference, but the record may be near the truth in stating that from an early age Plautus was connected with the theatre (perhaps as an actor). The prologue to the *Asinaria* gives the author's name as *Maccus*; the prologue to the *Mercator* gives it (in the genitive) as *mactici* (*Macci Titi*?); at the end of the *Casina* in "A" it is given (in the genitive) as *T. Macci Plauti*. The poet Accius, however, seems to have distinguished between Plautus and Titus Maccus. It will be remembered that *Maccus* was the clown in the *Atellanæ fabulae* (q.v.) and that *Plautus* is said by Festus to mean *planis pedibus* (cf. *planipes*, "mime"). The other prologues which give the name give it as "Plautus."

There is no certain evidence as to the dates of the plays. *Cistellaria* (201 ff.) refers to approaching victory over the Carthaginians. The supposed reference in *Miles Gloriosus* (211 ff.) to the imprisonment of the poet Naevius is perhaps itself the source of that story. Evidently Plautus' plays were popular and were revived after his death (see the post-Plautine prologue to the *Casina*). The works of other dramatists came to be attributed to him; by Varro's day the number of his plays had risen to 130. Varro made out a list of 21 (evidently those now known) which he said were universally agreed to be genuine (perhaps on grounds of style); others he himself accepted on grounds of style but did not include in the 21; still others he rejected. He can scarcely have been right in excluding the *Commorientes* (attested as Plautine by Terence and Accius) and, perhaps, the *Colax*, mentioned by Terence as either partly or doubtfully Plautine.

Attempts to arrange the plays in chronological order, on the evidence of topical allusions, metrical development, etc., must be regarded as speculative. What one scholar thinks a topical allusion by Plautus another will ascribe to the Greek original and yet another to a post-Plautine hand. Metrical variety is indeed characteristic of Plautus; but the prominence of the so-called "lyrical" metres might just as plausibly be attributed to the poet's youth as to his age. (See, however, W. B. Sedgwick, "The Origin and Development of Roman Comic Metres," *Classica et Mediaevalia*, 10, pp. 171-181, 1949.)

Indebtedness and Originality.—The plays of Plautus are based on Greek originals of the New Comedy, of which original examples are to be found in the fragments of Menander (including the *Dyscolus*, discovered in 1956). But Plautus was not a mere translator. This was shown by K. M. Westaway (*The Original Element in Plautus*, 1917) and Eduard Fraenkel (*Plautinisches im Plautus*, 1922); later, Italian scholars pointed to the vitality and verve which pervade all his work. On the other hand, there are passages in which he does not hesitate to take over allusions which can hardly have been intelligible to a Roman audience; e.g., the reference in the *Rudens* to Stratonice, a musician of the time of Alexander the Great. Terence refers twice to Plautus' "carelessness" as a translator, says that he omitted a scene from *Diphilus' Synapothnescontes* in his *Commorientes* and implies that he himself is following Plautus' example in his own practice of borrowing from a second original. Of large-scale remodeling there is no evidence; Aulus Gellius speaks rather of difference for the worse in style. Are the prologues mainly Greek, or Plautine, or post-Plautine? The romanization of the plays by way of allusions to towns in Italy, to the streets, gates and markets of Rome, to Roman magistrates and their duties and to Roman laws and the business of Roman law courts, banks, comitia and senate, etc., still leaves the structure Greek. Frank inconsistency is shown by his use, side by side, of the contemptuous expressions *barbarus* (applied to the Romans) and *pergræcari*, "to play the Greek" (applied to the Greeks). Frequently, as in passages in the *Aulularia*, the *Poenulus* and the *Pseudolus*, he seems to take delight in casting dramatic illusion to the winds.

But as an adapter for the Roman stage Plautus is nothing less than masterly. His command of Latin is such that his plays read like original works. Some of his characters stand out so vividly from his canvas that they have ever since served as representatives of certain types of humanity; e.g., Euclio in the *Aulularia*, the model of Molière's miser. Alliteration, assonance, deft use of metre for dramatic effect, plays upon words and happy coinages of new terms give his plays a charm of their own. "To read Plautus is to be once for all disabused of the impression that Latin is a dry and uninteresting language," wrote Franz Skutsch in *Die Kultur der Gegenwart* (1905). It is a mistake to regard the Latin of Plautus as "vulgar" Latin. It is essentially a literary idiom, based upon the language of Roman society in his day.

Characters and Plots.—The characters in his plays are the stock characters of New Comedy (though there may well be a suspicion that he has heightened the farcical element, perhaps under the influence of native Italian farce). The finer insight into human nature and the delicate touch in character drawing which Terence presents in his reproductions of Menander may be missing, but there is wonderful life and vigour and considerable variety in Plautus' characters. Their language is often downright and sometimes obscene, but, as has been well said, "the coarseness of Plautus' plays is not as great as is sometimes supposed" (John N. Hough, "Miscellanea Plautina," *Transactions of the American Philological Association*, 71, p. 186, 1940). The careful reader will take note of occasional touches of serious thought, examples of which are to be found in the *Pseudolus* (683 ff.); the *Stichus* (124); the *Rudens* (1235–1248), etc. The *Captivi* is the story of the heroic self-sacrifice of a slave; the *Amphitruo* is a mythological burlesque; the *Rudens* tells of shipwreck and treasure trove. But most of his plays depend for their main interest on intrigue. In the *Menaechmi* and *Amphitruo* and as a subordinate element in the *Bacchides* the theme of mistaken identity is to be found.

Metres.—In the metrical structure of his plays Plautus (no doubt following the earlier Latin dramatists) made an important change from the Greek model. The New Comedy had confined itself for the most part to the metre of dialogue (the six-foot iambic trimeter), occasionally relieved in moments of excitement by the trochaic tetrameter catalectic (seven and a half feet), which latter was accompanied by the pipe. Plautus greatly developed this trochaic metre in its Latin form (trochaic septenarius); it is actually more common than the iambic senarius (six-foot line), the only metre not accompanied by the pipe. But he used many other metres as well, all accompanied by the pipe; in fact the senarius or metre of unaccompanied speech (*diuerbium*) is only about half as common as the metre (whatever its form) of *canticum*, or declamation supported by the pipe. The *cantica* are not mere inserts or accessories, like the songs introduced in the Shakespearean drama; they comprise two-thirds of the text. The effect was probably not that of full song but rather that of the recitative "patter" of W. S. Gilbert, in which the words and rhythm are important and the music simply supports the rhythm. In *Stichus* (758 ff.) the piper (*tibicen*) is given a drink, and while he is drinking the metre changes for seven lines to iambic senarius. The *tibicen* was on the stage throughout the play; in *Pseudolus* (573a) he is asked to supply a solo.

The origin of the *cantica* has been much debated. Leo put forward the view that Plautus derived their metrical structure from contemporary Hellenistic music-hall songs; Fraenkel suggested that some earlier Latin dramatist had endeavoured to enliven comedy by introducing the metrical variety which he found in Greek tragedy; A. M. G. Little and others have sought the origin in Italian popular comedy (see *Harvard Studies in Classical Philology*, 49, p. 226, 1938). The individual metres employed were not indeed invented by Plautus; they are adapted from Greek and are common to Roman tragedy and Roman comedy, however, Plautus handled them with peculiar literary and dramatic skill.

Reputation.—Plautus held the stage until the end of the republic. Aelius Stilo, Cicero's teacher, praised his Latinity. Cicero, though in the *Orator* he found fault with the iambs of the Latin comedians generally as *abiecti* ("slovenly"), admired

Plautus' type of wit as *elegans, urbanum, ingeniosum, facetum*. Varro ranked him above all other Latin comic dramatists for dialogue. Horace in the *Ars Poetica* is a more severe critic: he is impatient with the taste of an earlier age which had admired Plautus' command of rhythm and jest, and in *Epistles* ii he accuses Plautus of carelessness in character drawing and indifference to everything except box-office success. The mime seems to have driven Plautus off the stage during the empire (though a ticket has been found at Pompeii giving admission to a performance of the *Casina*, and Arnobius says that the *Amphitruo* was performed in the reign of Diocletian). But he was still read; Aulus Gellius praises his style; Sidonius Apollinaris ranked him above the Greeks in wit; Jerome, after a night of weeping over his own sins, would console himself by reading Plautus; Eusebius praised him. In the middle ages he seems to have been best known as the supposed author of the *Querolus* (5th century A.D.). Only the first eight of his plays were known to Petrarch and other scholars at the beginning of the Renaissance; but in 1429 Nicolaus Cusanus brought to Rome a manuscript containing the 12 later plays; this event gave a strong impulse to the study of Plautus, who took rank as one of the great dramatists of antiquity.

Influence on Modern Literature.—Carl von Reinhardt in his *Spätere Bearbeitungen plautinischer Lustspiele* (1886) deals at length with the influence of Plautus on modern literatures. In the 15th century Italian scholars were producing Plautus' plays, new Latin plays and new Italian comedies (the *commedia erudita*) based on Plautus and Terence. In 1484 the *Aulularia* was presented on the Quirinal. An important play on the theme of the *Menaechmi* was *Gl'Innannati*, by the members of the Sienese Academy; this was translated into Spanish as *Los Enganados* by Lope de Rueda. In the 16th century Plautine influence was strong in Germany, Holland and France. In England the *Menaechmi* was performed by the boys of St. Paul's school in 1527. Nicholas Udall's *Ralph Roister Doister*, the first English comedy, was written about 1552; it is based on the *Miles Gloriosus*. Shakespeare's *Comedy of Errors* (about 1591), based upon the *Menaechmi*, with additional material from the *Amphitruo*, is thought to reflect the poet's Latin studies at school; his Falstaff and Parolles and Ben Jonson's Captain Bobadil owe much to the Plautine braggart warrior; the *Taming of the Shrew* has been influenced by the *Mostellaria*. In *Hamlet* II, ii, 377–382, Polonius says "The best actors in the world . . . Seneca cannot be too heavy nor Plautus too light." Ben Jonson's *The Case is Altered* (1609) is adapted from the *Captivi* and the *Aulularia*. Thomas Heywood adapted the *Amphitruo* in his *Silver Age* (1613), the *Rudens* in his *Captives* (1624) and the *Mostellaria* in his *English Traveller* (1633). John Dryden's *Amphitryon* (1690) is based partly on the Latin *Amphitruo* but chiefly on Molière's adaptation. Henry Fielding's *Miser* (acted 1732) rests on Molière's *L'Avare* rather than on the *Aulularia*. In 1929 Jean Giraudoux scored a resounding success with his *Amphitryon* 38, based on the *Amphitruo*.

PLAY, ANIMAL. At the beginning of any discussion of play in animals it is necessary to emphasize that understanding of the subject is extremely limited and coloured by anthropomorphisms, comparisons with human behaviour. The factual evidence consists exclusively of descriptions of a wide variety of responses that have been lumped arbitrarily together in the cate-

gory of play. The explanations and interpretations are speculative, deductively derived and untested. Some of the theories purporting to elucidate the causes and results of play are emotionally appealing but scientifically unsound; others appear plausible and may be valid, but none has been subjected to stringent objective verification.

Characteristics of Play.—The general characteristics of playful behaviour in animals as set forth by most students of the subject can be stated briefly: (1) It is almost universally agreed that in animals, as in men, playful responses carry an emotional element of pleasure. (2) Play is characteristic of the immature animal rather than of the adult; mature individuals sometimes play, but apparently less frequently than juvenile members of their species. (3) The majority of students concur in the belief that play differs from nonplayful activities in having no immediate, utilitarian result affecting the continued existence of the individual. (4) The type of play is characteristic of the species; furthermore, the nature and amount of play exhibited by members of a particular species vary according to evolutionary position. (5) Play is more common, occurs during a greater portion of the life span and appears in more diversified form in the higher animals than in the lower.

These generalizations refer to the commonly accepted characteristics of play. They are descriptive rather than analytical; and they cannot be used as explanations or interpretations.

Types of Behaviour Regarded as Play.—*General Bodily Activity.*—Young children take delight in racing about a room at top speed, stamping violently upon the floor, shouting loudly in utter abandon. Many young animals display similar behaviour. Colts, calves, kids, puppies and kittens expend vast amounts of energy in vigorous locomotor activity to no apparent biologically useful end. They gallop, run, bound and gambol to the point of apparent exhaustion. Many observers regard this behaviour as a form of play. It is assumed to constitute an outlet for surplus energy, to bring pleasure to the performer and to lack any practical purpose.

Youthful Practice of Adult Activities.—The African lion cub lies in hiding and creeps forth, belly close to the ground, to stalk and leap upon an unsuspecting brother or sister. Two puppies wrestle and roll in mock combat, sinking tiny teeth into thick fur and uttering infantile growls. Twin lambs face each other with heads lowered and forefeet pawing the earth; charging forward, they meet head-on and tumble awkwardly on the grass. The common element in such activities lies in their resemblance to similar behaviour patterns that the animal will display in somewhat different form later in life.

There are, however, several significant differences between the behaviour of the young and the adult individual. These responses, when they appear during infancy, do not terminate in the same result they will achieve in the adult stage. The kitten's chase of a ball or a blowing leaf mirrors the cat's pursuit of a mouse; but in one instance food is obtained and in the other it is not. The puppy's battle with his brother reflects the adult dog's combat with other grown animals; but in the infant's struggle no damage is inflicted. The young animal's performance is often imperfect and incomplete; whereas that of the adult is relatively polished and well integrated. From such observations it was deduced by Karl Groos and others that this type of play serves to prepare the animal for a more efficient adult life. It is thought that incomplete and imperfect instincts are modified, strengthened or suppressed during the practice period of youthful play. C. Lloyd Morgan suggested that the play period of infancy permits the practice of vital responses under conditions in which error and incompleteness are not fatal. The perfection of essential reactions is thus held to take place before the animal is subjected to the exigencies of an independent existence, wherein the forces of natural selection are constantly operating to weed out inefficiency and the penalty for error may be sudden death.

It seems probable that this theory may hold good for the play of certain higher mammals. The chimpanzee, for example, passes through a lengthy period of infancy and childhood during which a number of highly important reactions are exercised and possibly

organized into biologically effective form. There is, however, no proof that the generalization may correctly be extended to include all examples of this type of behaviour. The kitten's play with small, moving objects may indeed improve its abilities as a mouser, but there is no factual evidence to prove or disprove the assumption. In some cases youthful practice is demonstrably unnecessary. It is certain, for example, that the common sex play of some animals, such as the immature rat, has no demonstrable effect upon the efficiency of adult mating performance. The existence of a preparatory function of play can be established only by direct test of each activity in each species.

Exploration and Experimentation.—Young animals often peck, scratch, claw, pull and bite at objects in their environment, and such activities are sometimes classified as experimental play. The puppy's destructive attentions to a book or pillow are interpreted as play that serves to acquaint the animal with the properties and potentialities of the object thus investigated. Similarly, certain reactions of the young animal to its companions can be listed under the heading of exploratory or experimental play. An eventually practical outcome of such behaviour is held to lie in its tendencies to promote the development of new modes of conduct and to inhibit biologically dangerous reactions. Although this assumed function of exploratory play is based chiefly upon *a priori* reasoning, there are some instances in which it can be shown to exist. Wolfgang Köhler reported that captive chimpanzees given stout sticks or poles soon devised a crude form of vaulting or jumping, using the pole as a sort of crutch. Originally this response was apparently indulged in as a form of amusement and was not used as a means of achieving any secondary objective. Although further test and observation would be necessary to establish the point, it seems probable that the pole vaulting response was a form of play and the outgrowth of experimentation with the stick. Later, however, when the chimpanzees were confronted with the problem of obtaining a banana suspended above their reach, they quickly turned the vaulting technique to good use, employing it as a means of getting the fruit.

Social Play.—Young British warblers are described as engaging in "tilting matches," during which each bird commands a perch and attempts to dislodge other birds from theirs. African lion cubs play "king of the mountain." When one assumes possession of a high spot of ground or climbs on top some low object, all others try to force him off and take his place. "Follow the leader" games occur in the repertory of several mammalian species. Otters have been observed sliding down muddy banks into the water, one after the other in quick succession, and then climbing out to repeat the performance time and again.

Young monkeys in the jungle often swing single file through the branches, each copying roughly the actions of the animal ahead of him.

The group play of chimpanzees is highly diversified, and often resembles certain human activities. Köhler's description of "dancing" is illustrative. Several chimpanzees start to march in single file around a box or post. Gradually their pace quickens, and they trot, often with emphasis upon one foot, so that a primitive kind of rhythm emerges; and as they trot and stamp the animals wag their heads in time with the rhythm. Other kinds of social play occur in this species; and O. L. Tinklepaugh suggested that this type of behaviour early in life enhances the individual's adaptability and co-operativeness, both of which are essential characteristics of the chimpanzee.

Play Between Species.—Although young animals of one species may investigate those of a foreign species, they do not often play together. Exceptions to this generalization sometimes occur when two domesticated animals are reared together.

Thus a dog and a goat may engage in mock battles if they have been associated long enough to establish friendly relations, so to speak.

The outstanding type of interspecies play is that which occurs between man and his pets. If any of the criteria of play that have been accorded common use are to be accepted, it must be agreed that the dog frequently plays with his master. The dog may enter into mock chases or battles with a man much as he would with

another dog. On the other hand, he will with equal willingness participate in a learned game such as fetching the ball or performing tricks without any material reward. It is significant that the animal may initiate the play and in many different ways signalize his desire to stimulate playful relations with the human partner.

Explanations of Play.—Several theories have been formulated in an attempt to elucidate the causes of playful behaviour. None is completely satisfactory although several are partially serviceable.

Surplus Energy Theory.—This holds that play is a safety valve, providing an outlet for unused vigour. This interpretation has little to recommend it. Energy is not stored up in the organism like water in a reservoir. Animals are either completely rested and ready to react quickly to stimuli from the environment, or they are tired and sluggish in their responses. All types of behaviour occur more promptly and persist longer in the rested individual.

The energy expended in play differs in no way from that used in nonplayful pursuits.

Joie-de-Vivre Theory.—A second attempt to explain play is found in the *joie-de-vivre* theory, which interprets play as the expression of a general exuberance, an overflowing enthusiasm for life itself. A serious objection to explanations of this type is that they add nothing to basic understanding of natural phenomena; they explain nothing. They involve merely the substitution of one word or phrase for another, with the meaning or significance of the new term being no more precise nor illuminating than the old.

Instinctive Theory.—The instinctive theory of play in animals was championed by Karl Groos, who interpreted all play as responses based upon inherited tendencies or predispositions. However, to label an act as "instinctive" is not to explain it; and although the form that play takes in various animal species is unquestionably influenced by hereditary constitution, the serious student of behaviour is still faced with the responsibility for determining the stimuli that evoke playful responses, identifying the physiological and psychological processes that mediate the behaviour, and describing in objective terms the eventual effects and results.

Future Theories.—Although no completely satisfactory explanation for the occurrence of play in animals is available, it is possible to predict with reasonable certainty the form which such a theory must assume.

1. In the first place it is obvious that no single hypothesis can be formulated to explain all forms of play in every animal species. The types of activity that have been labeled "play" are so variable in form and complexity that a different interpretation is indicated for each major category.

2. It must be recognized that playful behaviour differs from nonplayful pursuits in subtle and often elusive fashion. There is no sharp border line between play and work for animals or for man. The two types of activity merge insensibly one into the other, and some complex responses may be partly play and partly work. Therefore, any acceptable definition of play must be based upon a list of predominating characteristics that combine to set it off from nonplayful behaviour, and cannot be derived from adherence to a single, rigid criterion such as nonutilitarianism or imperfect, juvenile performance. It is, for example, permissible to state that playful reactions as a class tend to lack the immediate, biologically practical results that normally accompany nonplayful responses, but it is not permissible to set up as an inflexible rule the dictum that no activity is play if it achieves a useful end.

3. Play must be explained in purely objective terms. A small start in this direction was made by workers such as J. B. Cooper, who suggested that the playful execution of certain behaviour patterns is characterized by the absence of the consummatory phase and by the rapid shift from one element of the pattern to another. Cooper noted that the play of lions is more prevalent on cool days, and tends to occur most frequently following a major change in the environmental situation (such as release of the ani-

mals from an indoor cage, the introduction of new lions into the pride, or the sudden appearance of the keeper). Much more extended analysis along lines such as these will provide the basis for an interpretation of play that is biologically significant and subject to direct test and verification.

The play of human beings is no more clearly understood than is that of lower forms, and the careful study of animal play offers potentially important results in the increased understanding of similar behaviour in man. See also ANIMAL BEHAVIOUR; PSYCHOLOGY, COMPARATIVE.

PLAYER PIANO, a piano equipped with a mechanical device conceived at first for playing music automatically—i.e., by means of pedals and hand levers—and later for reproducing the playing of a pianist. In its original form as the Pianola, patented in 1897 by a U.S. engineer, E. S. Votey, it was a mechanism placed in front of the keyboard and operated by the player's hands and feet. The notes of the music were in the form of perforations on a paper roll which passed over a tracker bar. Foot-operated pedals and hand levers controlled the release of air by pneumatic devices which set in motion hammers that struck the notes on the keyboard. Control of dynamics and accentuation was principally obtained by the pedals, while the levers were used to bring the melodic line into relief. Later this mechanism was built into the body of the piano. The roll and tracker bar were fitted in front of the hammers and the hand levers on a ledge in front of the keyboard. The foot pedals were lowered over the piano pedals. A considerable range of expression in both dynamics and tempo was available to the operator, who could thus perform music without having acquired a keyboard technique.

In the early 20th century several companies manufactured player-piano rolls that reproduced with considerable accuracy performances by distinguished figures, among them Alfred Cortot and Debussy. These performances were played on the "reproducing piano" and some of them were later transferred to phonograph records. The player piano also attracted composers, who were able to write for the keyboard without considering the limitations of the human hand. Stravinsky's *Étude* for pianola (1917) and Hindemith's *Toccata* for mechanical piano (1926) are among such works, and the resources of the player piano were widely explored by the U.S. composer Conlon Nancarrow (b. 1912). The vogue of the pneumatic player piano reached its height in the early 1920s, with some resurgence of popularity in the U.S. in the 1950s and 1960s. Its decline was attributed to the diffusion not only of piano music but of all forms of instrumental and vocal music by phonograph, radio, and television.

PLAYFAIR, LYON PLAYFAIR, 1ST BARON (1818–1898), British scientist and reformer, was born at Chunar, Bengal, on May 21, 1818. He was educated at five universities, including St. Andrews and London, and took his doctorate at Giessen, Ger., under J. von Liebig, whose *Chemistry of Agriculture* he translated. He was professor of chemistry at the Royal Institution, Manchester, 1843–45, and at Edinburgh University, 1858–69. Meanwhile he sat on numerous committees of inquiry, including the royal commission on the health of towns whose report (1846) laid the foundations of modern sanitation. He played an important role in organizing industrial exhibits for the exhibition of 1851 at the Crystal Palace in London. As secretary of the department of science (1853–58), Playfair advocated—without success—the use of chemical weapons in the Crimean War. He was a Liberal member of Parliament for the universities of Edinburgh and St. Andrews, 1868–85, and for South Leeds, 1885–92. In 1873–74 he was postmaster general and then presided over a commission that regulated clerkships in the civil service. From the spring of 1880 he served for three years as chairman of committees in the House of Commons, encountering and overcoming much obstruction. He was knighted in 1883; held minor office in Gladstone's home rule government of 1886; and was made a baron in 1892. He died in London on May 29, 1898.

See Sir T. Wemyss Reid, *Memoirs and Correspondence of Lord Playfair* (1899).

PLAYFORD, JOHN (1623–c. 1686), English bookseller and music publisher whose best-known work, the collection of traditional tunes, *The English Dancing-Master* (1650, but dated 1651), is an important source for English traditional music. Born in Norwich in 1623, by 1648 he had established his business in London where he became a clerk of the Temple Church and moved to the Inner Temple. His numerous publications, which include songs, catches, and instrumental music for cittern, lute, and harpsichord, reflect the taste of English amateur musicians of the latter half of the 17th century.

The friend as well as publisher of most of the English composers of his time, Playford was himself a competent musician, as may be seen from the songs and psalm settings by him that appear in his collections. His *A Brief Introduction to the Skill of Musick*, a handbook on music theory and practice, went into many editions between 1654 and 1730. In 1694 it was revised by Henry Purcell, who completely rewrote the section on composition, originally by Thomas Campion with additions by Christopher Simpson. Playford died in London, probably about November 1686. Of the several elegies on his death, one, "Gentle Shepherds, You That Know," by Nahum Tate, was set to music by Henry Purcell.

The English Dancing-Master, a collection of tunes for country dances, set for the fiddle, went into numerous editions between 1650 and 1728. Other Playford publications include: John Hilton's *Catch that Catch can* (1652); *Select Ayres and Dialogues* (1652–69); *Court Ayres* (1655); and *Musick's Handmaid* (1663).

Playford's son HENRY PLAYFORD (1657–c. 1709) continued the family business, which from 1696 he conducted in his own name. As well as bringing out new editions of his father's publications, he issued a small number of new works, notably John Blow's "Ode on the Death of Mr. Henry Purcell" (1696) and two posthumous collections of music by Purcell, *Orpheus Britannicus* (1698–1702) and *A Choice Collection of Lessons for the Harpsichord or Spinnet* (1696). Henry Playford also engaged in organizing concerts in London and Oxford and in picture dealing; by 1707 he had retired from music publishing. He died in London, probably in 1709.

PLAYGROUNDS: see PARK AND PLAYGROUND.

PLEADING, that branch of the law which governs the successive formal papers in which litigants in the opening stages of a lawsuit set forth the facts upon which they claim legal relief or challenge the claims of their opponents to such relief. See PRACTICE AND PROCEDURE.

(C. E. CL.)

PLEBISCITE, a vote of all the electors in a country or given area on some specific question, such as approval of a transfer of sovereignty or of a ruler's assumption of authority. The most familiar example of the use of the plebiscite in French history was in 1852, when the *coup d'état* of 1851 was confirmed and the title of emperor was given to Napoleon III. Unlike a referendum (*q.v.*), a plebiscite is not a normal method or procedure of voting.

As a means of settling the destination of populations and territories, the plebiscite was first used in the French Revolution to legitimize the wholesale annexations of territory made by the conquering French republic, and subsequently by Napoleon I. It was revived by Napoleon III and applied (successfully for him) in the case of Nice and Savoy, and (successfully for Victor Emmanuel) in the duchies of north Italy during the years 1859–60. The peace conference of 1919 proposed the taking of 17 plebiscites to settle difficult national questions, of which 8 were actually held. One of these, the Turkish plebiscite in Transcaucasia, was a farce. Others, which decided the fate of Allenstein and Marienwerder, of the Burgenland, the attribution of the northern and southern zones of Schleswig, the partition of Upper Silesia, the fate of Klagenfurt and the economic destiny of Luxembourg had substantial and important results.

By a plebiscite of Jan. 14, 1935, the Saar, which had been administered by the League of Nations since 1920, voted to return to Germany. Another plebiscite in 1947 favoured France but on Oct. 23, 1955, a third plebiscite rejected a Europeanization proposal and led to a Franco-German agreement on July 4, 1956, to reunite

the Saar with Germany on Jan. 1, 1957.

PLECOPTERA, the order of insects known as stone flies. The immature stages are aquatic, living in streams and rocky lake margins. The female lays several thousand eggs, discharging them in masses into the water. The nymphs are active and elongate, have long antennae and a pair of long "tails." Some forms have gills, but most do not. They feed on microorganisms, decaying organic matter or other insects. Nymphs may be found in clumps of rotted leaves, masses of debris or beneath submerged logs and stones. When mature, the nymph crawls out of the water and attaches itself firmly by its claws to a rock or tree trunk. The nymphal skin then bursts along the back and the adult emerges.

BY COURTESY OF THE ILLINOIS STATE NATURAL HISTORY SURVEY

STONE FLY (ISOPERLA CLID)

(Left) adult, length about 0.8 in.; (right) nymph, length about 0.6 in.

The adults are soft-bodied and range in length from $\frac{1}{2}$ to $1\frac{1}{2}$ in., plus the tails (minute in some forms). They have long, many-segmented antennae, and usually two pairs of membranous wings folded flat over the back. In a few species the wings are mere stubs. Most species are black or dark brown, but some are bright yellow or leaf green and others may be marked with orange or red. Stone flies fly rather slowly, but run actively. They are found on stones, foliage or tree trunks along the edge of a stream, or hiding in crevices of bridges or bark. Most species emerge from the water in spring, but there is a fairly large group of winter species, and a few in summer and autumn. Most adults do not feed, but some species eat algae, pollen and bud exudates. All forms are important as fish food and in general stream ecology.

The order Plecoptera contains about 1,200 species classified in nine families, distributed throughout the world. There are about 450 species in North America, 34 in the British Isles. Australia and New Zealand contain many primitive forms.

Fossil stone flies appear first in the Permian period, but are reasonably common only in the middle Tertiary amber of the Baltic region of Europe.

PLEDGE OF ALLEGIANCE TO THE U.S. FLAG.

This pledge was first published in the juvenile periodical *The Youth's Companion* on Sept. 8, 1892, in the following form: "I pledge allegiance to my Flag and the Republic for which it stands; one nation indivisible, with liberty and Justice for all." The words "the Flag of the United States of America" were substituted for "my Flag" in 1924, and the pledge was officially recognized by the U.S. in 1942. In 1954 "under God" was added, making it read: "I pledge allegiance to the flag of the United States of America and to the Republic for which it stands, one Nation under God, indivisible, with liberty and justice for all." A controversy arose concerning the authorship of the pledge of 1892. Claims were made on behalf of both James B. Upham, one of the editors of *The Youth's Companion*, and Francis Bellamy, an assistant editor. In 1939 a committee of the U.S. Flag Association ruled in favour of Bellamy, however, and a detailed report issued by the Library of Congress on July 18, 1957, concluded that "the Bellamy claim to authorship rests upon the more solid ground."

PLEHVE (PLEVE), VYACHESLAV KONSTANTINOVICH (1846–1904), Russian statesman, a firm upholder of the autocratic principle, bureaucratic government, and class privilege, was born on April 20 (new style; 8, old style), 1846, in Kaluga province, the son of a russified schoolteacher of German descent. He served in the department of justice from 1867, and in 1881, shortly after the assassination of the emperor Alexander II, was appointed director of the police department in the ministry of the interior. His efficiency in suppressing the terrorist movement earned him promotion to the post of deputy minister of the interior in 1884. He became head of the imperial chancellery in 1894 and acting minister and state-secretary for the grand duchy of Finland in 1899 (appointment confirmed 1900).

Plehve's appointment as minister of the interior, which S. Yu. Witte had previously blocked, came in April 1902, at a time when unrest was growing among all sections of the population. His approach to political and social problems was that of a skilled police investigator: he endeavored to set the different elements in the opposition against one another, neutralizing some and bending others to do his will. To silence the liberals he made conciliatory gestures accompanied by measures of intimidation. To deflect the industrial workers' discontent against their employers rather than the government he promoted "patriotic" labour unions managed by police agents. He fomented national antagonisms by an energetic policy of russification, applied with particular harshness against the Armenians and the Finns. He encouraged anti-Semitic propaganda, which in April 1903 led to a pogrom at Kishinev. When these methods failed, he entertained the idea that "a victorious little war" might help to consolidate the absolutist regime, and lent his support to the adventurist policy in Korea which provoked the conflict with Japan. On July 28 (N.S.), 1904, Plehve was assassinated in a St. Petersburg street by E. S. Sazonov, of the Socialist-Revolutionary party. It might be said that he fell victim to his own methods, for it later transpired that the coup was planned by E. F. Azef (1869–1918), a double agent working simultaneously for the revolutionaries and the police. (J. L. H. K.)

PLÉIADE, LA, the name given to a group of seven writers of the 16th century whose leader was Pierre de Ronsard and whose spokesman was Joachim du Bellay (*q.v.*). The other members of the group were Jean Dorat, J. A. de Baïf, Rémy Belleau, Pontus de Tyard, and Étienne Jodelle (*q.v.*). The name (derived from the seven stars of the Pleiades) was taken from that given by the Alexandrian critics to seven tragic poets of the reign of Ptolemy II Philadelphus (285–246 B.C.). The aim of the *Pléiade* was to enrich the French language and literature by discreetly imitating and borrowing from the classics and the Italian poets of the Petrarchan school. See FRENCH LITERATURE: 16th Century.

PLEIADES, an asterism, or star cluster; in mythology the seven daughters of Atlas and Pleione, and sisters of the Hyades (*q.v.*). Because of their grief at the death of their sisters or at the sufferings of their father, they were changed into stars. In another account, the Pleiades and their mother met the amorous hunter Orion (*q.v.*) in Boeotia; for five years he pursued them through the woods, until Zeus translated them all—Pleione and her daughters, Orion and his dog—to the sky. This is one of the few myths really astronomical in origin, for it is based on the relative positions of the constellations in the sky. The names of the sisters are Alcyone, Asterope, Electra, Celaeno, Maia, Merope and Taygeta; one is always dim or invisible, because she is Electra mourning for Troy, or Merope, who is ashamed of having wedded a mortal, Sisyphus. All the Pleiades became the ancestresses of divine or heroic families. The early winter rising and spring setting of the Pleiades (Lat. *Vergiliae*) are important dates to the farmer. (For an American Indian legend, see DEVILS TOWER NATIONAL MONUMENT.)

See H. J. Rose, *Handbook of Greek Mythology*, 5th ed. rev. (1953).

The stars are situated in the constellation Taurus (*q.v.*). They are referred to in the Old Testament (Job ix, 9; xxxviii, 31). The brightest star is Alcyone (η Tauri), of the third magnitude. This group is physically connected, being distinguished from the background stars by community of proper motion. Photographs show a faint nebulosity filling the whole region; there is little

doubt that this is rarefied matter made luminous by stimulation of the radiation of the hot stars comprised in it. The distance of the Pleiades from the solar system is estimated at 100 parsecs (300 light-years), but is not very certainly known.

Alcyone and the other bright stars are of the hottest type of spectrum (Type B) and give out several hundred times as much light as the sun.

PLEISTOCENE EPOCH. This is the sixth of the seven epochs that constitute the Cenozoic era (*q.v.*) of geological history (if, as is indicated on the accompanying geologic time chart, the Recent is taken as the seventh and the Pleistocene is not separated as the Quaternary era). By recommendation of the commission, 18th International Geological congress, the nonglacial Pleistocene (Greek *pleistos*, most, and *kainos*, recent) is defined on the basis of its fauna and separated from the preceding Pliocene by this means. Broadly speaking, however, it is thought to coincide with a period when glacial and interglacial conditions alternated over a large part of the earth's surface and because of this it is often known as the Glacial epoch or the Great Ice Age. During the glacial ages, widespread continental ice sheets repeatedly covered large areas in the northern hemisphere and alpine glaciers were more numerous and extensive in both the northern and southern hemispheres. During the interglacial ages, the climate seems to have been as warm or warmer than the present. The glaciated areas were reclothed with vegetation and repopulated with animal life and soils were formed. This epoch, the major part of the Quaternary period, is believed to have lasted several hundreds of thousands of years. It is generally regarded as having been terminated by the melting away of the latest of the great ice sheets, but at the same time it is also recognized that the Recent epoch of warm climate is not dissimilar to the interglacial ages, though shorter, and therefore the conditions of the Pleistocene glacial epoch have continued uninterruptedly to the present day.

This article is divided into sections and subsections dealing with various aspects of the epoch. The general geology of the period is considered under QUATERNARY. In addition to the cross references to related articles given under the several headings in this article see also ARCHAEOLOGY: Prehistory; GLACIER; MAN, EVOLUTION OF; PALEOBOTANY; PALEONTOLOGY.

Following are the main divisions of this article:

- I. The Glacial Concept
- II. Extent of Glaciation
 1. Areas of Continental Glaciation
 2. Source-Areas of Glacial Radiation
- III. Revolutionary Effects of Glaciation
 1. Effect of the Continental Glaciers
 2. Effects Beyond the Glaciated Area
 3. Warping of the Earth's Crust
 4. Fluctuations of Sea Level
- IV. The Glacial and Interglacial Ages
 1. Subdivisions of the Latest Glacial Age
 2. Nonglaciated Regions
 3. Duration of the Glacial Epoch
- V. Life of the Pleistocene Epoch
 1. North America
 2. Europe
 3. Early Man
- VI. The Glacial Climates
 1. Character
 2. Causes

I. THE GLACIAL CONCEPT

The concept of an ice age, when climates were colder and glaciers were far more extensive than they are at present, was first advanced by A. Bernhardt (1832) and Louis Agassiz (1837). Agassiz conceived the idea in Switzerland as the outgrowth of examining evidence earlier pointed out by scientific colleagues that certain glaciers in the Alps had formerly extended far down their valleys. He confirmed his views after a field study in Scotland in 1840, and extended them still further after he went to the United States in 1846 to spend the rest of his life.

Prior to the announcement of this glacial hypothesis naturalists commonly viewed the extensive glacial deposits and the widespread evidence of glacial erosion in the lowlands of both Europe and North America as the work of a cataclysmic flood (many believed

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	Began (Millions of Years Ago)
CENOZOIC ERA			
Quaternary	(Recent - last 11,000 years)	Early man	2+
	Pleistocene	Large carnivores	10
Tertiary	Pliocene	Whales, apes, grazing forms	27
	Miocene	Large browsing mammals	38
	Oligocene	Rise of flowering plants	55
	Eocene	First placental mammals	65-70
MESOZOIC ERA			
Cretaceous		Extinction of dinosaurs	130
Jurassic		Dinosaurian zenith, primitive birds, first small mammals	180
Triassic		Appearance of dinosaurs	225
PALEOZOIC ERA			
Permian		Reptiles developed, conifers abundant	260
Carboniferous	Upper Pennsylvanian	First reptiles, coal forests	300
	Lower (Mississippian)	Sharks abundant	340
Devonian		Ambulians appeared, fishes abundant	405
Silurian		Earliest land plants and animals	435
Ordovician		First primitive fishes	480
Cambrian		Marine invertebrates	550-570

it to have been the biblical deluge), or of a temporary submergence of the lands beneath the sea, with or without icebergs to help carry the large quantity of stones and boulders visible in the deposits. Not until about three decades after Agassiz' first announcement were the majority of scientific men on either side of the Atlantic convinced that glaciers rather than water had been responsible for these features. The term "drift," still applied to glacial deposits in general, dates from the time when the submergence hypothesis was widely accepted.

II. EXTENT OF GLACIATION

1. Areas of Continental Glaciation.—The convincing evidence of the former, much greater extent of glaciers is so generally accepted that it need not be presented here. The areas within the northern hemisphere that were formerly ice-covered are shown in the accompanying maps (the less extensive glaciers in the southern hemisphere are not illustrated). The mountainous western part of North America was occupied by a vast complex of glaciers which throughout most of the Canadian sector formed a nearly continuous covering of ice. The vast area from the Atlantic to the Rocky mountains, Canada and the northern part of the United States (as far south as New York city, Cincinnati, O., Carbondale, Ill., St. Louis, Mo., Kansas City, Mo., and Pierre, S.D.) were buried beneath an ice sheet (the Laurentide ice sheet) that had its source in Canada and also reached north to the Arctic ocean. The Laurentide ice sheet overtopped the White mountains in New Hampshire and so was at least 5,000 ft. thick in that region. This is the greatest minimum thickness that is shown by direct evidence, but it is considered probable that this ice sheet was 5,000 to 10,000 ft. thick throughout the greater part of its extent.

Greenland and Iceland were almost entirely ice-covered. Nearly half of Europe—from the North Cape off the north coast of Norway south to Kiev on the banks of the Dnieper—was covered by a single vast ice sheet (the Scandinavian ice sheet) which is believed to have attained a maximum thickness of 10,000 ft. Much of Siberia was overspread by mountain glaciers and by a great ice sheet (the Siberian ice sheet) on its northwestern plain. The Alps, the Caucasus and the Pyrenees in Europe and most of the high mountains on other continents carried glaciers of varying dimensions. The antarctic continent was even more nearly completely ice-covered than now, and the glaciers of the southern Andes spread westward to tidewater in Chile and eastward onto the pampas of Argentina. The highest mountains of Hawaii, Japan and New Guinea were marked by glaciers.

At present about 5,800,000 sq.mi (about 10.4% of the land area of the globe) are covered by glacier ice, but 98% of this ice is in the distant higher latitudes of Antarctica and Greenland. In contrast, when glaciers were at their maximum they extended into

temperate latitudes now the sites of highly organized civilizations and abundant agricultural and manufacturing production.

2. Source-Areas of Glacial Radiation.—During the early part of the last glacial age, the Wisconsin, the great Laurentide ice sheet over Canada had two primary areas of glacial radiation, one known as the Labradorean area located over the highlands of Labrador and eastern Quebec, and the other known as the Keewatin area located on the plains of Manitoba and adjacent territory of Ontario and Hudson bay. Later there was another area of almost equal importance, the Patrician, which developed south of Hudson bay and sent ice lobes southward through the Lake Michigan basin to form the moraines around the southern end of that basin and westward and southwestward through the Lake Superior basin into northern Wisconsin and northeastern Minnesota. The Keewatin ice lobe was crowded westward by it but even so the Keewatin ice received sufficient snowfall and possessed the energy to advance nearly as far south as Des Moines, Ia. Over the Cordilleras of western Canada the excessive snowfall, though much greater than today's, failed to form a continuous ice cap because of the rapid movement of the valley glaciers, especially on the west side, and the calving of icebergs into the sea.

The Scandinavian ice sheet had its origin on the high divide between Norway and Sweden. The Siberian ice sheet possibly began as small glaciers on three separate highlands: the Putorana mountains, the Byrranga ridge on the Taimyr peninsula and the Severnaya Zemlya archipelago.

A consideration of these ice fields makes it appear that they were all in response to a changing glacial atmospheric organization measurably different from the present; some ice fields began on plains, some on highlands, all necessarily being in the paths of maritime air masses charged with moisture. These ice fields varied in relative importance from age to age. During the Nebraskan age the Keewatin was the dominant field. During the following Kansan both fields were important. During the Illinoian, the third glacial age, the Labradorean area of radiation was preponderant and the Keewatin played a minor role.

This history emphasizes the fact that the nature of the atmospheric organization is unpredictable. The facts lie in the stratigraphic record. (See also *The Glacial Climates*, below.)

III. REVOLUTIONARY EFFECTS OF GLACIATION

1. Effect of the Continental Glaciers.—The northern part of North America and of Eurasia as well suffered profound changes from continental glaciation. The features of the latest glacier are indeed climactic. In North America the Great Lakes—the greatest fresh-water bodies on earth—are due more to glacial scour on a grand scale of former lowlands than to glacial deposition and later crustal deformation that followed the unloading of the earth's crust by the melting of the continental ice sheet. The moraines of glacial drift that lie beyond the basins are in large part the debris resulting from the glacial scour. The lake floors have irregular contours due to both glacial scour and deposition. However, the present outlines of the Great Lakes were assumed when crustal deformation tipped the land southward and helped to fix the present outlets. Northern Lake Michigan is more than 100 ft. shallower than when the glacier scoured it, and the northern part of Lake Huron and Georgian bay is something like 600 ft. shallower.

The lakes, muskegs, embossed and striated rock and other features of the irregular topography of Canada, the 10,000 lakes of Minnesota and large portions of the terrain of North Dakota, South Dakota, Wisconsin and Michigan are mainly such as only the processes of a continental glacier can bring about. New England and areas adjacent to it show the beautiful flowing lines of glaciated hills once buried deeply beneath the great ice sheet that terminated in the Atlantic. The lake basins among the hills, the anomalous sources of streams, the setting of the lakes and the strewing of the countryside with boulders and stony deposits are also features that result from glaciation. Maine has its eskers (rounded ridges of sand and gravel) crossing hill and dale, marking for mile after mile the courses of subglacial streams.

To the south and southwest of Lake Michigan, westerly and

southward from Lake Erie, southwest from Saginaw bay, and in northern Iowa and the eastern Dakotas, the spreading continental glacier made a plains country and left upon its retreat a successive series of moraines that fashioned the country into a rhythmic succession of ridge-and-plain topography remarkably suited to agriculture and transportation. This central interior lowland, however, is not all glacial. The glaciers left within it a driftless area of about 10,000 sq.mi., a topographic "island" of rugged hills and valleys branching treelike (dendritic) in pattern and made only by running-water erosion, a relict of preglacial times left between the Keewatin and Patrician ice fields and unmodified by them. Regardless of the direction of his travel, the motorist can see in contrast these pristine erosional forms of the driftless area and the bordering, newer and higher glacial landscape which has beneath it the older stream-eroded topography.

Most of the ancient master streams that preceded the glacial invasion did not survive. The ancient Teays-Mahomet river which once had its source in the distant western fringe of Virginia and which flowed northwesterly and westerly, eventually crossing the present course of the Ohio river and traversing central Indiana and central Illinois to Havana where it joined the ancient Mississippi, indeed formed one of the master valleys of the great interior of the continent. The Nebraskan and Kansan glaciers which crossed it transversely finished it off. This ancient valley was discovered only recently by a study of thousands of records of well drilling. The present course of the Ohio river along the southwestern boundary of Ohio is a consequence of this geological accident to the Teays-Mahomet valley, as is the upper portion of the Wabash river. One hundred fifty miles of the course of the present Mississippi river above the mouth of Illinois river is also

NORTHERN PART OF THE NORTHERN HEMISPHERE SHOWING AREAS GLACIATED DURING THE PLEISTOCENE EPOCH

Arrows show principal directions of flow (much generalized) of former glaciers, where information is available. Base from Hydrographic and Map service, Can. Polar Equidistant projection. Glacial data from many sources, notably Glacial Map of North America published by the Geological Society of America; Great Soviet atlas; E. Antevs, Gerasimov and Markov

an accident of continental glaciation, as is the Missouri river for 500 mi. in North and South Dakota.

These phenomena of the glacial age in North America are in a real sense duplicated in continental Europe—the glacial topography, lake regions, terminal and recessional moraines, buried valleys and other features—but there is no counterpart of the Great Lakes. A vast river flowed across northern Germany, along the southern part of the North sea floor and through the English channel because the normal drainage to the north was blocked by the Scandinavian ice sheet. (The English channel and much of the North sea floor were then dry land.) Capacious abandoned valleys excavated by the previous drainage are present in the north German plain. Where the land surface sloped toward the ice sheet, there were formed large temporary lakes, one shore of which was against the glacier ice. Lakes of great extent, now drained, also originated in this way in Ontario, Manitoba and the Great Plains region of Canada.

The people of many other parts of the North American continent marvel at the fertile soils of the north central states. It is common to refer to them as glacial. In the main, however, they are not derived from glacial drift but from loess, a silt picked up, carried and deposited by terrific glacial winds. The greatest thickness of loess in the middle west is along the east or southeasterly side of wide valleys containing silty glacial outwash and along the margin of the Iowan drift sheet, where the loess mantle averages 50 ft. or more and extends over the adjacent uplands in decreasing thickness, fineness and lime content. The shells of air-breathing snails, forms whose habitat is commonly the open woodland, make up the chief fossil fauna. In central Illinois some 10 ft. of the loess occurs under the Tazewell or Middle Wisconsin drift which has protected it from oxidation. Here peaty and woody remains of the original vegetation still occur in the loess, some in layers, thus recording pauses in the deposition. Beyond the terminal moraine and the protective cover of the Tazewell there are no plant remains, merely thin layers of orange-coloured iron oxide representing the iron residue of the former plant layers.

Niagara falls, one of the natural wonders of the world, is a product of the glacial age. It was initiated when the melting of the ice uncovered the cliff at Lewiston, N.Y., and opened a lower outlet for the waters of Lake Erie. That this occurred fairly late in geological times is shown by the fact that the falls have receded only about seven miles at a rate that is measurable.

The fertile Red river valley of the north is the former bed of Lake Agassiz whose natural outlet to Hudson bay was blocked until the Laurentide ice sheet was virtually melted. Its maximum area far exceeded the combined area of the Great Lakes. It had two histories, Lake Agassiz I and Lake Agassiz II, the first following the melting of the Mankato ice, the second the melting of the Valdres ice. Its outlet was of great volume, flowing like a torrent down the Minnesota and Mississippi rivers, widening their valleys, steepening the bluffs and truncating the headlands.

The basin of Lake Agassiz I was entirely overridden by the advance of the Valdres glacier which built the Big Stone moraine at Ortonville, Minn. When the Valdres ice retreated, the waters of Lake Agassiz II were obliged to cut a new outlet, narrow and gorgelike compared to the wide Minnesota river valley below Ortonville. Though of shorter duration than Lake Agassiz I, Lake Agassiz II lasted long enough to form beaches and a smooth floor out of a moderately undulating ground moraine topography, but the gravel of the beaches shows little water wear. Upon the complete melting of the glacier the lake, from its very south end, drained into Hudson bay, thus beheading the Minnesota river and forming a new river system, the Red river. The area today is an important wheat-growing region.

Lake Winnipeg and other water bodies in Manitoba are relicts of ancient Lake Agassiz II. A similar water body formed in the Baltic sea basin of northwestern Europe and over the adjacent coasts of Sweden and Finland, its overflow being through the submerged channel between Denmark and Sweden. A lake of similar origin is reported in the headwater region of Irtysh river, western Siberia. Obstructed by the Siberian ice sheet the lake overflowed southward into the ancient Aral sea, at that time probably a part

of the Caspian sea-Black sea-Mediterranean water body.

The various outlets of the glacial Great Lakes, which were also held back by the ice sheet, hold interest too because of their great size. Among these overflow routes may be mentioned: (1) from Chicago to the Illinois river valley and thence to the Mississippi river; (2) from Fort Wayne, Ind., via the Maumee and Wabash river valleys to the Ohio river; (3) from Lake Erie via the Mohawk river valley to the Hudson river; (4) from North Bay, Ont., via the Ottawa river valley to the St. Lawrence river. The old lake shores are variously marked by distinct cliffs, beaches and bars, many of which later served the early Indian as travel routes and still later were adopted in part for highways.

In the course of early geological investigations the students of glacial geology were amazed to find that some of the later beaches, which have a northward trend, rise higher and higher to the north, the oldest one reaching 600 ft. higher at North Bay than farther south. Thus was born the concept that the ice load had depressed the earth's crust and that removal of the ice permitted it to rise. The response was tardy but still continues, as accurate and refined measurements prove. Similar and equally striking phenomena occur in northeastern North America and northwestern Europe. The first-formed beach in the Baltic, following the shrinkage of the Scandinavian ice sheet, is now found in places as much as 700 ft. above sea level (see also *Warping of the Earth's Crust*, below).

The valley glaciers of the Cordilleras, the Alps, Carpathians and other high mountains in both the northern and southern hemispheres deepened and widened the pre-existing valleys, steepened the valley sides and excavated basins in the bedrock of the valley floors.

Farther down the valleys glaciers built up side ridges with the rock debris that they had acquired, in many cases hundreds of feet high (lateral moraines), and made ridges across the valleys from side to side (end moraines). Some lateral moraines consist partly of debris washed and avalanched onto the sides of valley glaciers from the steep slopes above. Melt-water streams coursing away from the glaciers spread boulders, gravel and sand over the valley floors, in some cases scores of miles beyond the farthest positions reached by the glaciers themselves. Far up in the mountains, ridge crests were sharpened to serrate forms by intense frostwork at those altitudes.

The world-famous, deep, steep-sided fjords of the coasts of Norway, Greenland, Alaska, Chile and parts of New Zealand were glacially carved from pre-existing valleys, and deepened far below sea level.

2. Effects Beyond the Glaciated Area.—The effects of the glacial climate and continental ice sheets extended far beyond the limits of glaciation. Rivers like the Mississippi and its strikingly spaced tributaries, the Ohio and the Missouri, and the Susquehanna and Columbia were greatly augmented by glacial melt water and overloaded with glacial sediment which they deposited as valley-train outwash all of the way to their receiving embayments. Sea levels were lower than they are at present and the extension of the Mississippi delta was controlled by such levels, only to become platforms upon which the later delta deposits were laid. Other river systems of the earth were affected similarly, the Volga, Don and Dnieper of eastern Europe being among those that are better known.

Mixed with some of the glacial sediment were ice-raftered boulders that reached the sea.

The valley trains that came from the glaciers of the Rocky mountains down the Missouri, the Platte and other rivers were sources of silt for winds to whip up and deposit as loess on the adjacent uplands. These valley-train sediments joined those from the upper Mississippi, so that loess in great thicknesses is found on the eastern bluffs of that valley as far south as Natchez, Miss., and beyond.

In the dry regions in low and middle latitudes on all continents there is impressive evidence both of former lakes where none now exist and of the former much larger size of existing lakes. These phenomena show that in these regions there were repeated times of greater precipitation and smaller evaporation than now occur. In

FROM W. M. LEIGHTON'S UNPUBLISHED MANUSCRIPT ON THE GLACIAL GEOLOGY OF ILLINOIS

OUTLINES OF GLACIAL MORAINES AROUND THE DISTAL ENDS OF THE GREAT LAKES SHOWING THE LOBATE ORGANIZATION OF THE LAST ICE SHEET

at least two cases (Lake Bonneville in Utah and Mono lake in California) a close time relationship has been established between the shore lines of the expanded lakes and glacial moraines. It is widely believed that the times of greater precipitation and less evaporation coincided with the glacial ages, and that the times of low water or even desiccation coincided with the interglacial periods.

The most widely studied of these dry regions is in the western United States, where no fewer than 68 former lakes have been identified by their abandoned shore lines and sediments. The largest of these lakes was Lake Bonneville which filled a number of coalescent intermontane basins in Utah, Nevada and Idaho and had a maximum area of more than 20,000 sq.mi. and a maximum depth of more than 1,000 ft. Since the last glacial age this enormous fresh-water body has been shrunk by evaporation to Great Salt lake, Provo lake and Sevier lake. Second only to Bonneville in size was Lake Lahontan, which had a maximum area of 8,422 sq.mi. in Nevada, Oregon and California. Pyramid lake, Winnemucca lake, the Carson lakes and Walker lake are its reduced successors. Some of the 68 basins, studied in detail, have yielded evidence of two and even three high-water stages separated by stages of partial or complete desiccation.

In Eurasia a similar record has been recognized. The Caspian sea and the Aral sea east of it had at least three expansions separated by drier times. Both basins filled and overflowed. Similar though less fully determined records have been reported from the larger undrained basins of central Asia. According to Max Blanckenhorn the Dead sea of biblical fame filled, at least once,

to four times its present length and to a height nearly 1,400 ft. above its present surface.

In northern, eastern and southern Africa the record of former lakes is closely similar. This repeated expansion and desiccation form the basis for a Pleistocene sequence for that continent.

The low temperatures responsible for the formation of glaciers in higher latitudes are believed to have been the basic cause of the lake expansions. Decreased evaporation directly resulted. As the ice sheets formed, they became the sites of high atmospheric pressure, which in turn pushed the principal middle-latitude belts of moving cyclones south of where they presently lie. These cyclones brought added precipitation to broad regions in lower latitudes that in nonglacial times were semiarid. As a consequence of increased precipitation and diminished evaporation, lakes either came into existence or were enlarged.

Because they were in part the result of increased rainfall, the high-lake stages are termed pluvial stages. The lakes appear to have reached their maxima at about the times when the ice sheets were at their maxima. Thus the glacial ages and the pluvial ages are thought to have been coincident and closely related in origin.

A conspicuous effect of the glacial climates in regions that lay a short distance beyond the ice sheets is the effect of frost heaving and solifluction. Solifluction is the slow creeping of soil, even on gentle slopes, as a result of freezing and thawing. It takes place today in arctic and antarctic regions and on high mountain summits in lower latitudes. The effects of solifluction in producing contortion of stratification and the patterned arrangements of stones resulting from frost-heaving of the soil are distinctive.

These effects also have been observed in regions never glaciated, such as southern England and northern France, and where the ground does not freeze today. They have been found also in various parts of the United States, even on the older drift sheets that extend beyond the younger. The inference is that during the glacial ages the temperatures in the regions surrounding the ice sheets were reduced enough to cause the ground to freeze and thaw vigorously, with resulting solifluction.

3. Warping of the Earth's Crust.—The building of large glaciers on the earth's surface during the glacial ages had two direct effects which in some places conditioned and resulted in greater changes than those attributable to erosion and deposition by the glaciers. These effects were conspicuous fluctuations of sea level and extensive warping of the earth's crust. The crust yields to excessive loading such as that induced by the great ice sheets. In the substratum below the rocky crust plastic flow transfers rock material outward away from the weighted area causing basin-like subsidence. When the ice sheet begins to melt the load on the crust is reduced, the direction of plastic flow in the substratum is reversed, the rocky crust bulges up very slowly in dome-like fashion and not until some time after the ice has disappeared are conditions restored to normal.

Along the seacoast and in regions of large glacial lakes extensive areas were submerged as they were uncovered by the melting ice. Waves and currents fashioned cliffs and beaches along the shores. The delayed updoming of the crust gradually caused the water to recede and at the same time warped the shore lines out of their original horizontal positions. Where there are several successive shore lines it has been possible to reconstruct the general form and progress of updoming. Doming movements related to the latest glacial age began so recently that they are still in progress, at least in eastern North America and in northwestern Europe. In the latter region the warping is concentric to an area in east-central Sweden. From this fact it is inferred that the Scandinavian ice sheet was thickest over that area. It is estimated that when the warping movement has been completed, thousands of years in the future, most of the floor of the Gulf of Bothnia will have become dry land.

In North America updoming is evident throughout the northern part of the vast region uncovered by melting of the Laurentide ice sheet. The great system of temporary glacial lakes, now extinct, that extended from Montana and the Great Plains of Canada on the west to northern New York and northern Ontario on the east left an array of shore lines whose measurements have yielded much information about the progress of updoming of the crust as the ice sheet disappeared. The thickest part of this ice sheet—at least during its later history—is inferred to have stood over the Hudson bay region because the warped shore lines are generally concentric to that region. Farther east along the St. Lawrence, in the maritime provinces of Canada and in Newfoundland, well-developed marine strand lines record submergence beneath the sea as the ice melted, followed by slow upwarping toward the northwest. This movement is still continuing throughout much of the region. It is predicted that the future completion of the doming movement will cause Hudson bay virtually to disappear.

4. Fluctuations of Sea Level.—The other direct effect of glaciation is the fall and rise of sea level throughout the world. As was correctly deduced by Charles Maclaren in 1842, the building of large glaciers when none existed before requires that vast quantities of atmospheric moisture be precipitated in the form of snow. As this moisture must come from the sea, the result is lowering of the sea level. Under warming climates the existing glaciers melt and large volumes of melt water are returned to the sea, thereby raising its level. The alternation of glacial and interglacial ages therefore has resulted in fluctuation of the sea level through a range of hundreds of feet, including levels both somewhat higher and much lower than today. It is generally thought that the sea level has stood, during glacial ages, perhaps 400 ft. lower than now, and during interglacial ages several scores of feet higher than now. These figures are arrived at by two methods: (1) calculation from estimated volumes of present and

former glaciers; (2) measurement of the heights of interglacial marine deposits and shore lines above present sea level; and (3) ascertaining the depth to which shoreward sediments and submerged channels occur.

Measurements made throughout the past century have established the fact that the sea level is rising at a rate of about 2.5 in. per century. This rise may be largely the result in many areas of the shrinkage of glaciers throughout the world, in others of subsidence of the earth's crust.

IV. THE GLACIAL AND INTERGLACIAL AGES

The U.S. middle west is the great classic area for clear records of successive glacial and interglacial ages of many thousands of years of duration. A mere layer of humus between deposits is looked upon with skepticism for representing a long time because humus can accumulate within a few decades. But when the soil zone includes deep leaching of limestone pebbles, deep oxidation and staining, and decomposition of granites, diorites and other silicate rocks as deep and intense as in modern soils on the younger drifts in the same latitude, then the record of an interglacial age is regarded as clear. Drift sheets of adjacent areas may also be compared in age by the relative degree of erosion which they exhibit under comparable conditions—the older the drift sheet the better developed the drainage pattern and the greater the erosion. A weathered drift beneath an unweathered drift is a reliable basis for recognizing the lower drift as much older than the upper. Along the sea coast if two drift sheets exposed in a sea cliff are separated by marine sediments containing warm-water fossils, the difference in age is apparent. Other means of differentiating drift sheets and the problems involved will not be discussed in this brief article. It should be noted, however, that the wood of buried soils is commonly coniferous even in such latitudes as central Illinois. The soil zone may be interglacial but it is questionable if the wood is. It is probably from the new forest that migrated southward in response to the oncoming glacial climate.

In North America the following sequence of glacial and interglacial stages (and ages) is recognized, the oldest at the bottom:

Wisconsin glacial
Sangamon interglacial
Illinois glacial
Yarmouth interglacial
Kansan glacial
Aftonian interglacial
Nebraskan glacial

All of these names originated in the upper Mississippi valley states where the type areas or sections occur. Certain correlations have been made with the Atlantic coast and with the Cordilleras. The Kansan is the surface drift over a large part of southern, western and eastern Iowa, northern Missouri, northeastern Kansas and eastern Nebraska. It also extends north into Minnesota and South Dakota. The Nebraskan is exposed beneath the Kansan at a great many places, rather commonly with a deep weathered zone preserved. For many years northeastern Iowa as far south as Dubuque was regarded as driftless, but patches of Nebraskan have been found on the upland ridges, making it quite certain that the Nebraskan ice sheet covered all of Iowa. A deposit of old weathered drift which some believe to be Nebraskan occurs on a high rock terrace in the mouth of the Wisconsin river valley. The Illinoian drift covers a large portion of Illinois and parts of southern Indiana and southwestern and eastern Ohio, and in places a fringe extends eastward beyond the Wisconsin. The Kansan seems to extend almost as far south in Indiana and Ohio as the Illinoian. Naturally the Wisconsin drift, being the youngest, is the surface drift over a much greater territory than the older drift sheets.

In the western mountains glacial deposits of at least three different ages have been found. The youngest is probably of Wisconsin age; the older ones have not been confidently correlated. Deposits as old as the Kansan, which in the middle states has been greatly eroded with only small ground moraine remnants remaining, are probably the oldest that can be positively identified in the mountains.

For many years the following classification of glacial deposits in the Alps by A. Penck and E. Brückner has been recognized:

- Würm glacial
- Riss-Würm interglacial
- Riss glacial
- Mindel-Riss interglacial
- Mindel glacial
- Günz-Mindel interglacial
- Günz glacial

Though some would add to this a suggested older deposit, the Donau, this classification seems to stand. In the area of continental drift in northern Germany and Denmark three stages are recognized. They are:

- Weichsel glacial (includes Brandenburg)
- Eem interglacial (marine)
- Saale glacial (Warthe, an upper member)
- Holstein interglacial (marine)
- Elster glacial

As in the case of North American geological literature the European literature is replete with suggested revisions, concerning the merit of which only the test of further investigations will tell. The fact, however, is patent that the effects of the glacial period were world-wide and it comprised a series of glacial and interglacial equivalents. Much research remains to be done to perfect the record. See also QUATERNARY.

1. Subdivisions of the Latest Glacial Age.—Because there is much hidden history of the older glaciations the Wisconsin offers the best opportunity to learn the nature of a glacial stage and from some standpoints the substages of the Wisconsin glacial stage hold greater interest than the older glacial stages. In North America the substages of the Wisconsin deposits are recognized from youngest to oldest as follows:

- Valders
- Mankato
- Cary
- Tazewell
- Iowan
- Farmdale

The Farmdale and the Iowan lobes are somewhat similar in that both ice sheets had their axial directions of movement diagonal to the succeeding stages; they were of short duration; and, like the fall season, they preceded the greater and more intense glaciation of the Tazewell. The Tazewell marks the "winter" of the glacial age. The ice sheet was bulkier, more persistent and extended farther than any other substage of the Wisconsin. It was inferred that the temperature reached its lowest point and snowfall was heaviest. The Cary marks a late resurgence of low temperature and heavy precipitation but it did not last long. The Mankato and Valders have the earmarks of late pulsations that were brief and portended another interglacial summer.

Some geologists are inclined to regard the Recent epoch as beginning when the Valders ice began to melt back. Others regard the Cochrane minor advance which terminated at Cochrane, Ont.—less than 200 mi. south of James bay—as the last substage. The former group of geologists thinks of the Cochrane as minor in degree and insignificant in the role of geologic processes that characterized the Recent.

In Europe as in North America, the last glacier did not steadily wane after the maximum advance, but there were climatic pulsations, each less severe and shorter than the preceding, resulting in glacial and intraglacial substages. International correlations of some of the interstadial intraglacial deposits have received much attention.

2. Nonglaciated Regions.—Southeastern California, now a very arid region, had a chain of large lakes, hundreds of feet in depth, of which the dry floor of Searle's lake is a successor. Radiocarbon dates of the upper part of the sediments agree closely with dates of the Wisconsin drift in Illinois. The overlying beds of salts and carbonates, which are 65 ft. to 100 ft. thick, are the result of evaporation in postglacial time. It does not seem too much to anticipate that an alternating series of salts and clays and silts will be found to match the older interglacial and glacial climates.

3. Duration of the Glacial Epoch.—The method of carbon

dating back to the beginning of the Wisconsin (Würm) rapidly came into use after 1949. W. F. Libby and J. R. Arnold developed the radiocarbon method by which discretely selected samples of wood, charcoal and certain other organic remains from deposits younger than 20,000 years could be dated. Radiocarbon C^{14} , a radioisotope of carbon with the mass number of 14 produced in the upper atmosphere by the bombardment of nitrogen by cosmic-ray neutrons, reacts with oxygen to form carbon dioxide. In that form it enters into all organic matter and all material exchangeable with atmospheric carbon dioxide, including carbonate in sea water. Upon death of any organism the radiocarbon diminishes by its own radioactive disintegration at a known rate. Therefore, by determining accurately the loss that has taken place from wood, for example, since its burial, the age of the wood, i.e., the time since burial, can be computed. The method of determination has been improved to include specimens somewhat older than 30,000 years. (See RADIOCARBON DATING; GEOCHRONOLOGY.) According to this method wood from the Farmdale loess, the oldest known Wisconsin deposit, is from 25,000 to 29,000 years old. This does not take into account the time required for the development of the Laurentide ice sheet, for its movement into the drainage basin of the upper reaches of the Mississippi and for development of the valley train from which the loess has been blown. The date of wood in the Iowan loess is 21,000 to 23,000 years; in Tazewell sediments, 15,000 to 19,000 years; Cary, 13,000 to 14,000 years; Mankato, about 12,200 years; and Valders advance, 11,400 years, all before the present time. E. Antevs, on the basis of varves and other geological evidence, disagrees. He calculates the date for the Mankato substage at about 19,000 years. In the early 1940s G. F. Kay estimated the retreat of the Mankato to have been about 25,000 years ago.

It is seen that radiocarbon dating allows only about one-half of the time permitted by the older estimates. In the second half of the 20th century research was being conducted to determine whether microorganisms of decay and other factors affect dating. Minute shells associated with low temperatures have been recovered from deep sea cores taken from the Caribbean and mid-Atlantic. Some C^{14} measurements have been made of them which show an age range from 10,000 to about 55,000 years. Those that record the lowest temperatures are about 15,000 years old, which is the latter part of the Tazewell. The feeling of conservative glacial geologists is that research should be pursued to acquire further and broader information. In the meantime respect is held for carefully documented stratigraphic work and sampling.

The extensive erosion of the Kansan drift and the prolonged exposure recorded by its zone of weathering are so impressive that it seems quite clear that the Kansan glacial stage was several hundred thousand years ago. The deep weathering of the Nebraskan before that drift sheet was superseded by the Kansan ice sheet, together with the apparent extensive erosion of the Nebraskan in northeastern Iowa, make the Nebraskan antedate the Kansan by an interval many times the duration of the Recent epoch. Hence, the over-all age of the Glacial epoch is at least several hundreds of thousands of years.

Another method of age determination, which has been applied to the older stages, is the "per cent of equilibrium method for uranium, ionium and radium," worked out by W. D. Urry. This method, which relies on the analysis of radioactive disintegration products, has been applied to ocean-bottom sediments in areas where they indicate alternating warm and cold periods, as for example alternating layers of globigerina ooze (see FORAMINIFERA) and red clay in the southeastern Pacific ocean. The dates obtained, according to Jack L. Hough, seem to correlate well with Pleistocene events on the North American continent, including six substages of the Wisconsin glacial stage (11,000, 15,000, 26,000, 37,000, 51,000 and 64,000 years ago), three substages of the Illinoian glacial stage (274,000, 310,000 and 330,000 years ago) and, by extrapolation, with the end of the Kansan glacial stage, about 700,000 years ago. The above data corroborate the former conclusions drawn from geologic study of the drift sheets that the Yarmouth interglacial, between Kansan and Illinoian times, was longer than the Sangamon interglacial between Illinoian

and Wisconsin times, and that the interglacial ages were much longer than the glacial ages.

One of the intriguing methods for studying the glacial history of the earth, also based on marine deposition but employing radio-carbon dating instead of the per cent of equilibrium method, is that of taking deep-sea cores some 60 ft. or more long where the rate of sea-floor sedimentation is slow. These cores bring up alternating layers of oozes of microorganisms and red clay. The fossil microorganisms include those that are sensitive to temperature changes (Foraminifera, diatoms) and thus they afford opportunity to study the ocean temperatures of the Pleistocene. These temperatures, based on carbon-isotope ratios and the C^{14} datings of the shells, provide comparison for this information from the ocean depth with the C^{14} datings of wood and other carbon remains from soils and peat beds of known geological positions on the land. This is a frontier of scientific investigation in glacial geology.

V. LIFE OF THE PLEISTOCENE EPOCH

The extent to which the plants and animals of the earth have become adapted to the new environment since the end of the glacial age is an indication of what can transpire in something like 10,000 years. The older glaciations, Illinoian, Kansan and Nebraskan, had similar effects on the life of those of the last ice age. Since the interglacial ages that followed are estimated to have had a duration of something like 100,000, 300,000 and 200,000 years respectively, it is to be inferred that the land surface from which the ice had retreated became completely reclothed with vegetation, and repopulated several times during the glacial period.

Mammalian life changed greatly both through extinctions and through the appearance of new forms. Among the new ones were zebuline horses, cattle, camels, certain elephants, rhinoceroses and a woolly mammoth, a distinctly cold climated form not known to have lived before the first glaciation. Horses and moose were immigrants near or at the close of the Kansan glaciation. The greatest number of the extinctions came in the period roughly from 5,000 to 10,000 years ago, and included all the camels, horses and ground sloths; two genera of musk oxen; peccaries; antelope-like ruminants; all but one species of bison; a giant beaver-like animal; a stag moose; and several kinds of cats, some of which were of lion size. The huge mammoths, larger than living elephants, which had become common throughout the United States also disappeared as did the forest dwellers, the mastodon and the woolly mammoth of tundra and level stretches. Their extinction in North America, as well as Europe, is credited to early man. Man's appearance in North America was rather sudden, probably taking place when there was a land bridge across the Bering strait.

1. North America.—There were forms that lived on the tundra close to the ice front—the woolly mammoth (*Mammuthus primigenius*) and the caribou; in the subarctic forest the mastodon, moose, stag moose, giant beaver (*Castoroides*), deer and bears; farther removed, the other elephants of the mammoth line, tapirs, peccaries and a variety of deer and carnivores; in the central Great Plains elephants, horses, bison, elk, antelope, ground sloths from South America and many small mammals. The late glacial forms that lived in Florida included the mastodon, elephant, camels, a huge bison, peccaries, deer, tapirs, horses, ground sloths, armadillos, several carnivores including a sabre-toothed cat (*Smilodon*), wolves and bears. In central Alaska the frozen ground of alluvial silt contains fossils of bears, wolves, foxes, badgers, wolverines, sabre-toothed cat, jaguar, lynx, woolly mammoth, mastodon, horses, camel, saiga antelope, four bison, caribou, moose, stag moose, elk, sheep, musk ox, ground sloth and various rodents. It is suggested that this fauna may be interglacial.

Today the Bering strait separates Alaska from Siberia. The fossil record indicates that this was a land connection one or more times during the Pleistocene. The Japanese current probably gave it a mild climate and permitted the growth of long thick grass like that on the Alaska peninsula. The immigrants and emigrants appear to have been entirely cold-temperate or boreal forms.

Not only may crustal warping have produced the bridge, but lowered sea level prevailed during the early and late parts of the different glacial ages when much sea water was still locked up in the ice sheets.

Immigration from South America is recorded in the ground sloths which came to live as far north as central Alaska. The North American horse and deer traversed the Isthmus of Panama to live in South America. (R. F. FT.; M. M. L.)

2. Europe.—The Pleistocene mammal fauna went through a series of striking changes in Europe as it did in North America. Basically there was a steady change as certain species like the elephants, rhinoceroses and horses evolved, while at the same time other forms became extinct against the competition of immigrants from the east. Superimposed on this progression, however, was an oscillation due to a north-south shift of animal population as the glaciers waxed and waned, so that faunas which were very similar appeared at two or more different times, separated by a fauna of quite different character.

The very earliest part of the Pleistocene (Villafranchian) produced some strange inhabitants of western Europe—lynx, several species of bear, a macaque monkey and the great sabre-toothed cat; *Machairodus*. The elephants included *Mastodon arvernensis*, but also the first of the true elephants, *Elephas meridionalis*. This fact, and the appearance of the true horses (in the form of *Equus stenonis*), is regarded by many as the criterion of the Pleistocene.

In the later part of the Lower Pleistocene (the Günz-Mindel interglacial stage, the Aftonian in North America, identified in *The Glacial and Interglacial Ages*, above), though the macaque monkey, sabre-toothed cat and *Elephas meridionalis* persisted, the latter was accompanied by a more advanced type, *trogotheri*. Two species of rhinoceros (*mercki* and *etruscus*) were present, a giant extinct beaver (*Trogotherium*) was found, and the red deer and hippopotamus made their appearance.

The Middle Pleistocene started with the Mindel-Riss, or Great Interglacial, with the macaque monkey and Merck's rhinoceros still lingering on. A deer, *Dama clactonianus*, was distinctive. For the first time the straight-tusked elephant (*antiquus*) appeared, with the great ox (the aurochs, *Bos primigenius*) and the bison and the modern species of horse; and most interesting of all, *Homo sapiens*. (Fossil specimens from Steinheim, Ger., and Swanscombe, Kent, Eng., are discussed in MAN, EVOLUTION OF: *Antiquity of Homo Sapiens*.) As the climate changed to the Riss glaciation, a characteristic cold-climate fauna replaced that of the preceding interglacial. For the first time appeared the woolly mammoth (*Mammuthus primigenius*) and woolly rhinoceros (*Tichorhinus antiquitatus*), both extinct, the bison and animals like the reindeer and musk ox which are associated with the arctic tundra.

The Upper Pleistocene started with the Riss-Würm, or Last Interglacial, and the fauna was once more "warm," with the hippopotamus, straight-tusked elephant, brown bear, beaver, lion, leopard, marmot, red deer and the giant elk (*Megaceros giganteus*). As the Würm glaciation developed, so a "cold" fauna very like that of the Riss glacial period once more migrated in—the woolly rhinoceros and mammoth, cave bear, lynx, arctic fox, bison, aurochs, musk ox, horse and arctic lemmings. After the vicissitudes of this last glaciation, the progress to the present-day climate included the extinction of the mammoth and woolly rhinoceros (whose frozen remains have been found in the Russian tundra), the elimination of the beaver and the driving to the far north of the reindeer and the musk ox. See F. E. Zeuner, *The Pleistocene Period* (1959). (F. W. SN.)

3. Early Man.—In the examination of the past for the physical and cultural records of man, the written record gives way to the archaeological record of pottery, drawings and carvings on the walls of caves and pieces of ivory, and artifacts of stone and bone, the basic materials of the science of archaeology. In the 1960s, available data on the physical anthropology of man—the family of Hominidae—predated the beginning of the Ice Age in Europe. Heidelberg man, a Pleistocene species of the genus *Homo*, lived at approximately the close of the Mindel glacial stage (Kansan in North America). Nonhomo manlike species, Archanthropic,

prophetic of man, appeared in Europe during the Günz-Mindel interglacial stage (Aftonian). The last of these are not known to have lived after the Mindel-Riss interglacial stage (Yarmouth). However, the time span from the beginning of the first interglacial to near the end of the Mindel-Riss interglacial is much longer than all subsequent time. Extinct fossil species of the genus *Homo* (paleoanthropic man)—Heidelberg, Neanderthal, Rhodesian and Solo—cover the period from the close of the Mindel glacial to the early part of the Würm glacial (Wisconsin). *Homo sapiens*, the present world-wide species, has lived since the close of the Mindel-Riss interglacial. Cro-Magnon man, the modern erect man, was found in fossilized condition in the Cro-Magnon cave in Dordogne, France. His appearance is dated as in the fourth glacial. (See also MAN, EVOLUTION OF.)

The skeletal parts show that marked evolution took place during the 1,000,000-year stretch of Pleistocene time, particularly in the brain, which increased greatly in size. The artifacts show a general progressive increase in perfection and adaptability, which in turn record an increase in intelligence and skill among the people who made them. These increases, however, apparently took place at different rates in different regions; very different degrees of culture flourished at the same time in different parts of the world. This has been learned in part through dating the various groups of artifacts and skeletal remains, both by means of fossil mammals that have been preserved with them and by identification of the deposits in which some of the remains occur with deposits of known glacial or interglacial age. Radiocarbon C^{14} datings have made significant contributions.

The record in the Americas does not extend as far back in time as that in the old world. No skeletons or artifacts dating from early in the Pleistocene have been found, but discoveries indicate that man may have come to America at about the close of the Sangamon interglacial or the beginning of the Wisconsin glacial.

VI. THE GLACIAL CLIMATES

1. Character.—At the height of the glacial ages at least 28% of the land area of the world was covered by glacial ice. At present more than 10% is so covered, but significantly this is in the higher latitudes. The same was probably true for the interglacial ages. Some differences between the present and one of the interglacial ages are apparent, however, from comparison of fossil faunas with the living forms.

Glacial cirques (theatrelike valley heads fashioned by the action of snow fields at the heads of individual glaciers in mountainous terrain) bear a rough general relation to the snow line or lower limit of perennial snow. Through measurements of the altitudes of cirques in many parts of the world the approximate position of the snow line at the height of the latest glacial age has been determined. Wherever measured, this former snow line is lower than the snow line of today—at the equator as well as in polar latitudes.

In order to determine the glacial-age climate of a coastal point A, a point B on the same coast is located by finding the place where the present snow line has the same altitude as the glacial-age snow line of A. The present climate of B is then taken as representative of the former climate of A. The method is rough, but over a wide region it gives consistent results. Coastal points such as A are seen to have received much greater precipitation than they do at present, and to have had mean annual temperatures of the order of 7° C. to 8° C. lower than now, whereas in interior regions the increase in precipitation and decrease in temperature, compared with present conditions, were less pronounced. In other words, the subpolar climate belts were shifted toward the equator during the glacial ages. This shift may have amounted to as much as 15° of latitude for the boreal, or northern, belt, less for the warmer belts.

The pluvial conditions of the dry regions of middle and low latitudes support this conclusion in that they appear to show equatorward shifting of the middle-latitude belts of rain-bringing cyclonic storms. The evidence of fossil animals in the northern hemisphere likewise indicates southward shifting of the cold northern climatic zone through many degrees of latitude.

On the other hand the evidence of fossil plants and animals indicates that during the interglacial ages the climatic zones were shifted toward the poles, and that at least once these zones, in the northern hemisphere, have been pushed north of the positions they occupy at present. It is generally believed, though it has not been conclusively proved, that these climatic shifts were synchronous throughout the world. In summary, the climatic changes were world-wide and apparently contemporaneous; the climatic belts were shifted alternately, equatorward and poleward; and changes in mean annual temperatures amounted to several degrees centigrade.

2. Causes.—The causes of these remarkable climatic changes have received the attention of geologists, astronomers, physicists and meteorologists for a century. Of the many hypotheses put forward, a few may be mentioned only to be dismissed: (1) Changes in the amount of volcanic or cosmic dust in the earth's atmosphere, thereby varying the thermal insulating effect of the atmosphere. This hypothesis encounters many objections and is wholly inadequate to meet the facts. (2) Displacement of all or part of the earth's crust relative to the earth's axis, thus bringing different regions into the positions of the poles at various times. This hypothesis is negated by the consistent relative positions of the climatic zones throughout long periods of time and by the lack of independent geophysical evidence of crustal displacement. (3) Broad uplifts of continents and localized uplifts of mountain masses, thus reducing temperatures and creating conditions favourable for the formation of glaciers. This hypothesis, which usually also applies to shifts in ocean currents, was proposed before the fact of the interglacial ages was fully established, and fails because it demands frequently repeated crustal uplifts and subsidences of which there is no independent evidence.

The basis of a theory that has received wide adherence was suggested by J. Adhémar in 1832. It was extended by J. Croll in 1875, and much later was elaborated, with variations, by M. Milankovitch, R. Spitaler, W. Köppen and A. Wegener, W. Soergel and others. This theory, sometimes termed "the astronomical theory," is based on the periodic changes that affect the earth's motion in three different respects: (1) eccentricity of the orbit (period 91,800 years); (2) inclination of the axis to the ecliptic plane (period 40,000 years); (3) shifting of the perihelion (period 21,000 years). These changes affect the distribution of solar heat received by the earth's surface, though they do not affect its total amount. The results of these changes can be plotted as a curve showing variations in the amount of heat received during the summer at any selected latitude. Because the three periods differ, such curves are nonperiodic. They show irregularly spaced maxima and minima of heat, which are taken by the advocates of the theory to represent the interglacial and glacial ages respectively. Four pairs or groups of temperature minima (nine in all), held to indicate four principal glacial ages, are represented as having occurred within the past 600,000 years.

Four objections to this theory may be mentioned: (1) it demands that the cold times alternate between the two polar hemispheres, yet there is no geologic evidence that such was the case; (2) it requires that at the equator there be little or no heat fluctuation, yet there is clear evidence in the east African mountains, directly on the equator, that the snow line there fluctuated throughout more than 3,000 ft. between glacial and interglacial ages; (3) the heat-fluctuation curves deduced from the theory show nine minima; these do not agree with the geologic evidence, which records only four glacial ages.

Another group of theories is based on the premise that there is a considerable variation in the absolute quantity of radiant energy emitted by the sun, and holds that terrestrial climatic fluctuations take place in accordance with such variations. E. Huntington's version of this idea laid emphasis on a supposed connection between solar energy and the incidence of cyclonic storms on the earth. Sir G. Simpson's version deduced an elaborate and ingenious scheme in which glacial ages are offset in time with respect to the maxima and minima of solar radiation. It applies best to the antarctic region. A. Penck's version deduces a direct connection between reduced solar radiation, world-wide

temperature reduction and glaciation. Although there is no proof whatever that large fluctuations in solar energy have occurred, the assumption that they have occurred appears to meet all the requirements for the causes of the glacial climates. See GEOLOGY; see also references under "Pleistocene Epoch" in the Index.

PLEKHANOV, GEORGI VALENTINOVICH (1856–1918), the founder and for many years leading exponent of Russian Marxism, was born at Gudalovka in Tambov province, on Dec. 11 (new style; Nov. 29, old style), 1856, the son of a landlord. As a student he was attracted to the Narodniki (q.v.) or Populists, and he became a member of the clandestine organization Zemlya i Volya (Land and Freedom). In 1879, however, objecting to the increasing emphasis laid on terror as opposed to mass agitation, he formed a splinter group, Cherny Peredel (Black Redistribution). Emigrating to Western Europe in 1880, he plunged into the study of Marxist literature and soon decided that "scientific socialism" alone offered a solution to the problems besetting the Russian revolutionary movement. In September 1883 he founded in Geneva a small circle, Osvobozhdenie Truda (Liberation of Labour) to spread Marxist ideas in Russia.

Plekhanov unequivocally condemned any attempt by a revolutionary minority to seize power on the people's behalf. The revolution, he maintained, must be the work of the masses themselves, in particular of the industrial proletariat. This class, guided by a militant social-democratic party, should lead the struggle of the entire Russian people against the "feudal" absolutist order; the ensuing "bourgeois-democratic" revolution would in turn pave the way for socialism and the dictatorship of the proletariat. A determinist, Plekhanov held that the advent of socialism was assured by the inexorable laws of historical development. In his philosophical writings he adhered rigidly to Marxist dialectical and historical materialism, and his works on aesthetic subjects were inspired by considerations of political utility. In both fields his views command official approval in the U.S.S.R.

In the leadership of the Russian Social-Democratic Workers' Party Plekhanov was eventually eclipsed by Lenin: Not without misgivings, Plekhanov collaborated with Lenin in publishing *Iskra* ("The Spark") and, at the 2nd party congress (1903), supported him against the Mensheviks; but in November 1903 the two men parted company. Plekhanov saw in Bolshevism a revival of Populist "Jacobinism": Lenin, he held, was seeking to turn the party into a pliant instrument with which to seize power and introduce socialism in Russia "from above," regardless of whether the objective historical conditions for it had as yet matured. During the revolutionary crisis of 1905–06 Plekhanov maintained that it was essential for socialists to collaborate with bourgeois liberals against absolutism, but his efforts to propagate this view among the party rank and file met with little success. A similar situation obtained in 1917, when Plekhanov at last returned to Russia. His standpoint, that the class struggle should be temporarily suspended in the interests of national defense, was unpopular with the war-weary masses.

In November 1917 he condemned the Bolshevik Revolution as a betrayal of Marxist principles. A few weeks later, threatened with violence by a band of revolutionary sailors, he had to flee from his home. He died, disillusioned, at Terijoki in Finland on May 30 (N.S.), 1918.

English translations of Plekhanov's works include *In Defence of Materialism* (1947), *The Role of the Individual in History* (1946), and *Art and Social Life* (1953).

See S. H. Baron, *Plekhanov* . . . (1963).

(J. L. H. K.)

PLETTENBERG, a town of West Germany in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, is 63 km. (33 mi.) SE of Dortmund by road. Pop. (1961) 28,380. The old centre of the town is bordered by suburbs. Notable buildings are the 11th-century Christuskirche, Brünninghausen Castle (1620), and the ruins of Burg Schwarzenberg (1300) on a nearby hill. Plettenberg is on the railway from Dortmund to Frankfurt am Main. Hardware and sheet metal are produced. First recorded in 1072, Plettenberg obtained town rights in 1387. In 1725 most of the town was destroyed by fire. (W. Hl.)

PLEURA, DISEASES OF. The pleura is a continuous thin sheet which lines the interior of the thoracic cavity (parietal pleura) and is reflected at the root of each lung to cover the entire surface of the lung (visceral pleura).

Pleurisy.—Inflammation of the pleura, which may occur as an accompaniment to almost any major lung disease, is often called pleurisy or pleuritis. The word is sometimes used in a loose and inaccurate manner to indicate any type of thoracic pain. The pain of pleural inflammation is usually sharp in character, well localized and clearly related to breathing.

Pleural Effusion.—Accumulation of excess amounts of fluid between the visceral pleura and the parietal pleura (pleural effusion) frequently results from pleural inflammation or circulatory congestion. The amount of fluid may be very great, even several pints, sufficient to prevent expansion of the lung and, hence, result in respiratory insufficiency. Small amounts are often difficult to detect except by X-ray examination. The fluid is usually clear and straw coloured but may be cloudy and occasionally tinged with blood.

Infection of the pleural space with tuberculosis, secondary to a tuberculous lesion in the lung, is a common cause of pleural effusion. The fluid is usually clear and straw coloured and contains moderate numbers of lymphocytes. It may contain tubercle bacilli, but often biopsy of a small portion of the pleura is necessary to establish the diagnosis. Often, but not always, it is possible to diagnose the associated tuberculosis of the lung by the usual methods. Treatment of tuberculous pleural effusion is usually effective when the specific antituberculosis chemotherapeutic drugs are administered, as for pulmonary tuberculosis. Untreated tuberculous pleural effusions are often followed by manifestations of lung tuberculosis after an interval of several months or several years of good health, during which latent period there may be no X-ray evidence or other indication of the infection.

Acute inflammatory diseases of the lung, including pneumonia (q.v.), are sometimes associated with pleural pain, and occasionally with accumulations of pleural fluid. The amount of such fluid is usually small, and it usually disappears promptly when the lung inflammation subsides.

Impaired circulation of blood in the lungs due to ineffectual heart action often leads to a seeping of fluid from the swollen and congested lungs into the pleural space. Treatment of the heart failure may relieve the congestion and permit resorption of the fluid. Often this requires the administration of diuretic drugs; limitation of sodium intake; rest; and administration of digitalis. Occasionally needle aspiration of the pleural fluid may accelerate improvement.

Empyema of the Thorax.—A collection of pus in the pleural space, known as empyema, is the result of severe and prolonged infection. Treatment is difficult and requires removal of the pus, either by repeated needle aspirations or by surgical drainage. Antibacterial drugs are selected which are active against the causative organism, hence bacteriologic examination of the pus is important. Surgical treatment sometimes requires the removal of large portions of the infected pleural membrane (decortication).

Tumours of the Pleura.—Most tumours which originate from the pleura can be classified as mesotheliomas. They may be either malignant or benign, and may be either localized or extended over a large area of pleural surface. Diagnosis is rarely possible without microscopic examination, and that necessitates surgical biopsy in most circumstances.

Cancer of the lung (bronchogenic carcinoma) often extends peripherally to involve the pleura, producing symptoms and find-

ings similar to those of infection. Malignant implants on the pleura of tumours originating elsewhere in the body are rather common in the latter stages of widespread metastatic cancer. Such implants often lead to marked pleural effusion, and the fluid is often bloody. Diagnosis is established by X-ray examinations and sometimes by biopsy. Treatment is difficult, but radiation, using either X-ray or radioactive isotopes, and chemotherapy with tumour-inhibiting drugs may provide some temporary symptomatic relief.

Chylothorax.—Rupture of the thoracic duct, a lymphatic channel which transmits chyle from the abdominal cavity to the large veins of the upper thorax, may lead to accumulation of chyle within the pleural space. This material is recognized by its milky appearance and its high fat content. The two commonest causes of chylothorax are injury and metastatic malignancy.

Hemothorax.—Accumulation of blood in the pleural space may be a serious result of injury, especially when there has been damage to the larger blood vessels of the chest wall. Sometimes the rupture of adhesions between visceral and parietal pleura, occurring in association with pneumothorax, will lead to occult bleeding, which may become serious before it can be recognized. It is possible for a patient to lose very large amounts of blood by this type of internal hemorrhage. Diagnosis often requires needle aspiration as well as X-ray examination, and treatment may or may not require open operation for repair.

Fibrothorax.—Pleural fluid may contain large amounts of fibrin, which may be deposited on the pleural surfaces and eventually organized into scar tissue. Sometimes this is sufficient to envelop all or a portion of the lung in a thick inelastic coating which limits lung expansion and impairs breathing ability. Surgical removal may improve respiratory function in selected cases. Small localized collections of fibrin are frequent and of little or no significance.

For other diseases of the chest, see LUNG, DISEASES OF; PNEUMOTHORAX; RESPIRATORY SYSTEM, DISEASES OF.

PLEVE, VYACHESLAV KONSTANTINOVICH: see PLEVNE, VYACHESLAV KONSTANTINOVICH.

PLEVEN, RENÉ (1901–), French statesman, twice premier of the Fourth Republic, was born at Rennes on April 13, 1901. After graduating in law from the University of Paris he became an industrial executive. In 1940, during World War II, he joined Gen. Charles de Gaulle, who gave him civilian responsibility for the colonies from 1941 to November 1944, when he became minister of finance in De Gaulle's first government formed in Paris. Plevén left the government with De Gaulle in January 1946 but did not long remain a Gaullist.

Plevén had been elected a deputy for Côtes-du-Nord in 1945 and was reelected subsequently. He was a leader of the Union Démocratique et Socialiste de la Résistance (UDSR), a left-centre group. He was twice minister of defense (1949–50 and 1952–54), and was premier from July 11, 1950, to Feb. 28, 1951, and again from Aug. 8, 1951, to Jan. 7, 1952. He helped to formulate the plan for the European Defense Community in 1950, but none of the cabinets to which he belonged was willing to stake its life on the ratification of the necessary treaty. He was foreign minister in Pierre Pflimlin's short-lived cabinet in May 1958.

Plevén did not oppose De Gaulle's return to power and left the UDSR in October 1958 when François Mitterrand induced it to oppose the new constitution, to which Plevén gave a qualified assent. In February 1959 he formed the Union pour une Démocratie Moderne. In 1966 he spoke against France's withdrawal from NATO. (P. W. C.)

PLEVEN (PLEVNA), chief town of the *okrug* (district) of that name in northern Bulgaria, is situated about 5 mi. (8 km.) to the east of the Vit River, a tributary of the Danube, at an altitude of 381 ft. (116 m.). Pop. (1961 est.) 72,171. The town has been known since Thracian times when it was called Storgosia (Stergezia), and it was later occupied by Romans and Turks. It is now a service centre for the surrounding fertile agricultural region, has food-processing industries, and manufactures textiles, machinery, ceramic articles, and cement. Plevén is a route centre and

an important junction on the main Sofia-Varna railway, having a branch line which connects with the small Danube port of Somovit, 25 mi. N. The town has several monuments and museums which commemorate various battles fought in and around Plevén, and also the important Liberation museum.

PLEVEN OKRUG lies between the foothills of the Balkan Mountains (Stara Planina) and the Danube. Its approximate area is 4,132 sq. km. (1,596 sq. mi.). Pop. (1963 est.) 357,100. The main rivers are the Danube, Iskur (Isker), Vit, and Osum, all of which are used for irrigation. The northern area is part of the Danubian Platform region where the rich black soil and summer rainfall allow good grain harvests. Grapes and fruit are grown and cattle are bred. Industries are varied and include timber and food processing. The chief towns of the district, besides Plevén, are Cherven Bryag, Levski, and Nikopol. (S. H. Br.)

The Battle of Plevén.—Plevén was the scene of a major battle during the Russo-Turkish War of 1877–78. Having crossed the Danube, a Russo-Rumanian army under Gen. Baron N. P. von Krüdener marched on Plevén but, on July 20 (new style; 8, old style), 1877, was stopped there by a Turkish army under Gen. Osman Pasha. After two further attacks (July 30 and Sept. 11–12) had been repulsed by the Turks, the Allies then began a siege; Plevén fell to them on Dec. 10, when the Turks, having failed to break through the cordon, surrendered. See RUSSO-TURKISH WARS.

PLEYEL, IGNAZ (JOSEPH) (1757–1831), Austrian composer and founder of one of the principal French firms of piano makers. The 24th child of a poor village schoolmaster, he was born at Ruppersthal, near Vienna, on June 1, 1757. He studied the piano under J. B. Vanhal and composition under Haydn, whose close friend he became. In 1776 he produced his puppet opera *Die Fee Urgele*, on a libretto derived from Voltaire and Chaucer, at Esterházy, and in 1780 his opera *Ifigenia in Aulide* was produced in Naples. In 1783 Pleyel was appointed deputy *maitre de chapelle* and in 1789 principal *maitre de chapelle* at the cathedral in Strasbourg, where in 1791 he became involved in the troubles of the French Revolution and barely escaped the guillotine. In 1795 he moved to Paris, where he opened a music shop, published the first complete set of Haydn's string quartets, and in 1807 founded the pianoforte factory which still bears his name. Pleyel was a prolific composer with a facile and spirited invention. A few of his numerous symphonies, concertos, serenades, and string quartets were revived toward the middle of the 20th century. He died near Paris, Nov. 14, 1831.

See L. de Fourcaud, *La Salle Pleyel* (1893); I. Klingenberg, *I. Pleyel und seine Kompositionen für Streichquartett* (1926).

PLIMER, ANDREW (c. 1763–1837), English miniature painter, was the son of a clockmaker at Wellington. With his brother Nathaniel (1757–c. 1822), who also became a miniature painter, he joined a party of gypsies and wandered about with them, eventually reaching London, where in 1781 he was engaged by the miniaturist Maria Cosway as studio boy. Her husband, Richard Cosway, the leading miniature painter of the time, then received him into his own studio. In 1785 he set up for himself in Great Maddox Street. He exhibited many times in the Royal Academy. His miniatures are of great brilliance and are in considerable demand among collectors. They are distinguished by the peculiar wiry treatment of the hair and by the large, expressive eyes that Plimer invariably gave to his female sitters. He died at Brighton in 1837 and was buried at Hove.

See G. C. Williamson, *Andrew and Nathaniel Plimer* (1903). (G. C. W.; X.)

PLIMSOLL, SAMUEL (1824–1898), British politician and social reformer who dedicated himself to achieving greater safety for seamen and whose name has been given to the mark that indicates the limit to which a ship may be loaded, was born at Bristol on Feb. 10, 1824. Before entering business on his own account as a coal merchant in 1853, he worked as a clerk. He became interested in shipping conditions, and strongly criticized "coffin ships," unseaworthy and overloaded vessels, often heavily insured, in which unscrupulous owners risked the lives of their crews. He entered Parliament as Liberal member for Derby in 1868, and, failing to secure passage of a bill dealing with the safety of shipping,

published *Our Seamen* (1873), which attacked the shipowners and made a great impression throughout the country. On Plimsoll's motion, a royal commission was appointed in 1873, and in 1875 a Merchant Shipping Bill was introduced, which Plimsoll, though regarding it as inadequate, resolved to accept. When the bill was dropped he lost his self-control, applied the term "villains" to members of the House, and shook his fist in the Speaker's face. He later apologized, but there was strong support for his view that the bill had been stifled by the pressure of the shipowners.

The government was pressed into passing a bill, which in 1876 was amended into the Merchant Shipping Act. This gave stringent powers of inspection to the board of trade and fixed the loading line for ships. Plimsoll was reelected for Derby in 1880, but decided to give up his seat. Later he was estranged from the Liberal leaders by their neglect of shipping reform. Moreover his views on other questions were frequently at variance with theirs. He became president of the National Amalgamated Sailors' and Firemen's Union in 1887 and three years later raised a further agitation about the horrors of the cattle ships. He died at Folkestone on June 3, 1898. (A. BRI.)

PLINY THE ELDER (GAIUS PLINIUS SECUNDUS) (A.D. 23 or 24–79), Roman savant and author of the celebrated *Natural History*, was born at Novum Comum (Como), in Transpadane Gaul. On this ground he claimed Catullus, a native of Verona in the same region, as a fellow countryman. His own writings and those of his nephew Pliny the Younger show that the date of his birth was in A.D. 23 or 24, that he must have come to Rome at an early age and that he practised for some time as an advocate. He saw military service in Germany. Under Vespasian, with whom he was on the most intimate terms, he served as procurator in Hispania Tarraconensis and elsewhere. He was in Africa, Gallia Narbonensis and Gallia Belgica and perhaps also in Judaea and Syria.

Finally Vespasian appointed him prefect of the Roman fleet at Misenum, in Campania, which Augustus had made one of the principal Roman naval stations. He was stationed at Misenum when, on Aug. 24, 79, there occurred the great eruption of Vesuvius which overwhelmed Herculaneum and Pompeii and cost Pliny his life. The circumstances are vividly told in a letter of the younger Pliny to the historian Tacitus. Pliny, wishing to assist those persons who were in danger, sailed from Misenum to his friend Pomponianus at Stabiae (Castellamare) on the southern shore of the Bay of Naples. There, in order to allay the fears of his friends, he dined, as his nephew says, "cheerfully, or what was equally splendid, with a pretence of cheerfulness," and then retired to rest. In the middle of the night, when stones and ashes were already falling about the house and the house itself was rocking alarmingly, he was roused and he and his party determined to seek safety in the open, binding pillows about their heads as a protection against falling debris. "Now it was day elsewhere," runs his nephew's account, "but there night darker and denser than any night, alleviated a little by numerous torches and lights of various sorts. It was decided to go out upon the shore and see at close quarters whether the sea now offered any prospect of safety; it still continued wild and adverse. There Pliny lay down upon a cast-off linen cloth, and once and again he asked for cold water, which he drank. Then flames and a smell of sulfur announcing the approach of flames caused the others to take to flight and roused him. Supported by two slaves he got upon his feet, but immediately collapsed, his breathing, I gather, being obstructed by the thickening vapour which closed up his wind-pipe—naturally weak and narrow and frequently painful. When day returned—the third (in English reckoning the second, i.e., Aug. 26) after the last day (Aug. 24) that he had seen—his body was found intact and uninjured, covered as he had been dressed. The appearance of the body suggested one sleeping rather than dead."

A list of Pliny's books in chronological order is given in a letter by his nephew: (1) *De iaculatione equestri unus* ("On Throwing the Javelin From Horseback, in One Book"), "written while he was serving as commander of a cavalry regiment with equal ability and care." (2) *De vita Pomponii Secundi duo* ("Life of Pomponius Secundus, in Two Books"), "the discharge, as it

were, of a debt due to the memory of a friend who had entertained a singular affection for him." Pomponius, described by Tacitus as a man "of refined character and conspicuous ability" was a tragic poet who had also a military career of some distinction. (3) *Bellorum Germaniae viginti* ("German Wars, in Twenty Books"), "in which he brought together all the wars waged between us and Germany. He began the work while he was serving in Germany, being admonished by a dream. The ghost of Drusus (stepson of Augustus and brother of Tiberius) who, having carried his conquest of Germany to the widest extent, died there, stood by him as he slept and commended to him his memory and entreated him to vindicate him from the injustice of oblivion." This work is cited by Tacitus, who probably used it in his *Germania*. (4) *Studiosi tres* ("The Student, in Three Books") "in which he instructs and perfects the orator from the cradle up." (5) *Dubii sermonis octo* ("Dubious Language, in Eight Books") "written in the last years of the reign of Nero when slavery had rendered dangerous every study of a free and elevated character." Fragments of the treatise were edited by J. W. Beck (1894). (6) *A fine Aufidi Bassi triginta unus* ("Continuation of the History of Aufidius Bassus, in Thirty-One Books"). The history of Bassus of which the terminal point is not known, Pliny continued down to his own day. (7) *Historiae Naturalis XXXVII* ("Natural History in Thirty-Seven Books"). This work alone is extant.

Pliny the Younger has given a description of his uncle's studious habits. He would call upon the emperor Vespasian before day-break and then after performing his official duties return home and devote what time remained to study. After a light meal, if it were summer and he had leisure, he would often lie in the sun while a book was read and notes and extracts were made: he never read a book without making extracts, holding that no book was so bad as not to contain something good. Next he frequently had a cold bath, a snack and a short siesta, after which, "as if it were another day," he studied until dinnertime. During dinner a book was read and notes were made. He rose from the dinner table in summer before nightfall, in winter within the first hour of night. Thus at Rome; but in vacations no time was exempt from study, save bathtime, and even then he had something read to him or dictated something, while he was rubbed and dried. When traveling he was accompanied by a shorthand writer armed with book and notebook and in winter provided with gloves. To procure time for study he was carried even in Rome and his nephew tells how he was once reproved by him for wasting valuable time in walking. When he died Pliny bequeathed to his nephew 160 volumes of extracts (*electorum commentarios*) "written on both sides and in the minutest hand," for which, when he was procurator in Spain and when the number of volumes was rather less, he had declined an offer from Larcus Licinus of 400,000 sesterces (c. £3,100).

The *Natural History*, which appeared with a dedication to Titus, son of Vespasian and his successor as emperor, two years before Pliny's death, is, as stated above, in 37 books. Book i has a general preface and contains a table of contents of the other books, to each being appended a list of the authors consulted. These lists contain the names of 146 Latin and 327 foreign authors. Book ii is devoted to a mathematico-physical description of the world and deals with the heavenly bodies—sun, moon, planets, fixed stars; various meteorological phenomena; the succession of the seasons; the earth's shape and surface phenomena—seas, rivers, springs and the like. The subject matter of this book affords Pliny an opportunity, of which he readily avails himself, to expound his own philosophic creed, which is a modified Stoicism. His view of nature is pantheistic. Books iii–vi are devoted to geography and ethnography. This is unscientific and uncritical but extremely valuable for the incidental facts which it presents. There is an interesting mention of maps of Armenia in book vi, 40.

Books vii–xi are occupied with zoology and are the most generally interesting section. The seventh book deals with man and is occupied less with the normal than with the marvelous and portentous, which the scientific creed of the author and his belief in the infinite power of *ingeniosa natura* enabled him to accept or at least not to reject outright. Thus there are tales such as would

have charmed the ear of Desdemona—of men whose feet were turned the wrong way; of the Mouthless Men (Astomi) who subsisted upon the mere fragrance of flower and fruit; of the Umbrella-feet (Sciapodes) who used their extensive feet as parasols to protect them from the sun; of monstrous births; of precocity or exceptional development of physical strength or speed, sight or hearing, and mental powers; of men who were unconscionably long in dying. Incidentally, Pliny here declares his disbelief in immortality. Book viii treats of terrestrial animals other than man. Here again, amid much that is interesting in detail, there is an unfortunate absence of scientific arrangement and an excessive proneness to accept the marvelous, of which he was so unconscious that he expresses surprise at the credulity of the Greeks (*mirum est quo procedat Graeca credulitas*). Hence side by side with sound science, which comes mostly from Aristotle and, so far as concerns Africa, from Juba, there is a host of imaginary animals—winged horses, unicorns and like monstrosities. Book ix deals with aquatic animals and scientifically is the soundest of all the zoological books, which is no doubt due to the fact that Pliny's information is mainly derived, at least ultimately, from the *History of Animals* of Aristotle, who treats of aquatic animals with unusual fullness. The marvelous in this book is chiefly represented by Pliny's belief in Nereids and Tritons and the usual stories of the human sympathies of the dolphin. Book x treats of birds, commencing, according to Pliny's practice of beginning with the largest, with the ostrich. Such classifications as he makes of birds are of an empirical kind and based on very superficial observations. The first part of book xi is occupied with insects—the bee being treated with some fullness—and the latter part with what may be called comparative anatomy. Books xii–xix deal, generally speaking, with botany, including forestry and agriculture, the subject of book xviii, which is one of the most interesting in this section. Books xx–xxvii treat of medical botany or the medicines derived from plants. Books xxviii–xxxii deal with other than botanical *materia medica*, i.e., with medicines derived from the bodies of man and other animals.

The remaining books are occupied with mineralogy and with metals and metallic products, the precious metals, gold and silver, being discussed in book xxxiii; bronze, bronze statuary, iron and lead in book xxxiv; chiefly painting in book xxxv; stone, including its use in building and sculpture, in book xxxvi, gems and precious stones in book xxxvii.

Pliny's *Natural History* is a storehouse of ancient errors, but there are many branches of ancient manners and culture, such as sculpture and painting, concerning which he gives valuable information which can be found in no other extant writer. His style is sometimes dry and abrupt and sometimes slovenly, but at other times strongly rhetorical, pointed or mannered. The influence of his work on later times was great. About three-quarters of the *Collectanea rerum memorabilium* of C. Julius Solinus (3rd century A.D.) were based on it, and on books xx–xxxii was based the *Medicina Plinii*, a compilation of the 4th century.

PLINY THE YOUNGER (GAIUS PLINIUS CAECILIUS SECUNDUS) (A.D. 61 or 62–c. 113), Roman author and administrator, nephew and adopted son of the elder Pliny, who left a collection of private letters of great literary charm which intimately illustrate public and private life in the heyday of the Roman empire. His official correspondence as a provincial governor is a unique set of documents, and his career is characteristic of those concerned with the management of the peaceful areas of the Roman empire.

Born c. A.D. 61–62 of a wealthy family at Comum in north Italy, he was educated at Rome and began to practise law when aged 18. He made a reputation in the courts of civil law, and later was in demand in the political court that tried provincial officials on charges of extortion. His most notable success was in A.D. 100, when he secured the condemnation of the proconsular governor of Africa, and of a group of officials from southern Spain. Meanwhile he had reached the highest grades of the administration by securing the titular posts of praetor in 93 and of consul in 100, despite the fact that he was the first member of his family to become a Roman senator. In this he owed much to the influence of friends of his uncle. Pliny had financial ability, and was head successively of the military treasury (*aerarium militare*) and of the senatorial treasury (*aerarium Saturni*) (A.D. 94–100). After administering the drainage board of the city of Rome—*cura alvei Tiberis*—(c. A.D. 104–106) he was sent (c. A.D. 110) by the emperor Trajan on a special mission to investigate corruption in the municipal administration of Bithynia. He apparently died there in office about two years later. His military experience was limited to a short commission on the staff of the governor of Syria at the beginning of his career, where his duties were financial. The details of his life are known from his letters, and from inscriptions set up in his honour at Comum.

Pliny, like his contemporary Tacitus, was a conventional man who accepted the Roman empire, serving under "good" and "bad" emperors alike, and making in his writings the conventional complaints against the latter. He concealed the preference which he secured from the hated Domitian, and even claimed, later, that he had been in political danger through his tenuous connection with the faction that had criticized Domitian and had suffered accordingly in a famous state trial in the year of Pliny's praetorship.

The Letters.—*Publication and Chronology.*—He published selections of his private letters in nine books, issued apparently in three or four groups at irregular intervals between 100–109. After essaying the state of the market with the first two volumes, possibly issued separately, since they contain no interconnecting links, he issued a series of five or six, in which the letters are arranged to a certain extent in interconnected series. The ninth volume contained a miscellany of mostly very short letters of uneven interest and uncertain date, which may well represent the residue of publishable material in his files before he left Italy for the governorship of Bithynia. The tenth book is a posthumous publication. The chronology of the letters has been much discussed. The material in the first eight books is chronologically coherent. Books i and ii overlap, covering events from after the death of Domitian in Oct. 97 to the early part of 100. Book iii touches events of the next three years. Thereafter books iv to vii inclusive (with the exception of iv, 9, for a special reason) are confined each to the events of about a 12-month period from 104–105 to 107–108. The last two books cover much the same period as vii, but contain a few letters from earlier periods of the correspondence. This chronology depends not only upon a number of dated or datable historical references, and of obviously continuous groups of letters, but also on a series of subsidiary cross-references and interrelations in the subject matter which have not yet received sufficient attention.

Style and Content.—The letters are neither imaginary epistles in the style of Seneca nor unimproved copies of daily correspondence like those of Cicero. They are carefully written occasional letters. The topics are very diverse. Each letter contains an item of recent social, literary, political or domestic news or sometimes an account of an earlier but contemporary historical

event, or else initiates moral discussion of a particular problem. Each has a single subject, and is written with considerable artifice in a style which mixes, in Pliny's terminology, the historical, the poetical and the oratorical manner, to fit the theme. Length depends on theme, but brevity is preferred. Pliny apologizes for the unusual length of certain letters. Whether they were all written as genuine letters is much discussed, but is the wrong question. Several are obvious literary revisions of more practical originals, as when he discusses a new building with his agent, but omits its dimensions. Touches of revision can be detected in some of the longest historical letters that most resemble formal essays (e.g., i, 5). The composition of these *litterae curiosius scriptae* ("letters written with special care") was a contemporary fashion which Pliny developed into a miniature art form, to which the closest parallel lies in the similar occasional verses of Martial. Pliny is a prose Martial, without the indecency. The form arose naturally in a wealthy and cultured class of interrelated families lacking rapid communications.

There are letters of advice to young men, often illustrated by anecdotes; short notes of greeting and inquiry to absent friends; descriptions of newly discovered scenes of natural beauty or of natural curiosities. There are compressed accounts of the lives and habits of famous men. Estate business is a frequent theme—crises in farming, famines, sales and floods. Forensic scenes play a large role; the longest letters describe the triumphs of Pliny in the political courts. Roman society is there in all its diversity—an aged and decrepit roué cheating his toadies in his last testament, or an octogenarian relict of the court of Nero maintaining bygone depravities in a more strait-laced age.

Pliny reveals himself as a successful and complacent, kindly man, patronizingly generous toward his juniors and inferiors, and smoothly tolerant of all but the most objectionable of his peers. His character is often unfavourably judged, but the model of the magnanimous man, which he consciously imitates, was honoured in antiquity as the highest pattern of human virtue.

Pliny was a shrewd man, who kept a careful eye on his landed estates, now discussing the pros and cons of a new purchase, now advising a friend how to prevent a municipality from wasting its endowments, now offering his wholesale buyer a price reduction when the grape market broke, with an eye to future deals, now modifying his system of rentals in order to keep the tenantry on his estates. Such letters reveal the abilities for which Trajan chose him to reorganize the municipal finances and local government of Bithynia. The tenth book of letters contains the minutes which he addressed to Trajan on sundry problems, and the emperor's replies. He consulted Trajan 42 times in a period of some 18 months. The topics include municipal expenditure on public works, the qualification of municipal councilors, the treatment of criminals and the prosecution of Christians.

Pliny has been criticized for lack of independent judgment and responsibility by those with little experience of modern bureaucracy, but it must be remembered that his province was lacking in archives and permanent administrative staff. Official documents were known only from copies held by plaintiffs and petitioners. Many problems required an alteration of the basic law of the province, or the amendment of an imperial edict. Others involved the rights of Roman citizens, or the privileges of independent imperial officials. Pliny was also anxious that his decisions should be based on general rules approved by the central government instead of on *ad hoc* decisions. Hence he had good reasons for the submission of most of his inquiries to the emperor at Rome, who only once reproves him for writing needlessly.

On eight occasions Pliny seeks Trajan's approval for large public building operations—theatres, aqueducts, baths, sports stadium, and a canal; it seems that Trajan initiated a rule that required central sanction for new municipal expenditure of this sort. Pliny was also anxious to secure Roman engineers and architects to supervise these works for a reason which Trajan failed to understand—that he did not trust the local experts, who had been responsible for extensive jerry-building. Pliny's humanity was in several instances notably greater than that of the emperor. In the affair of the Christians his examination of prisoners led him to

query the assumption that the new cult was associated with vicious practices. Though ready to execute Christians as members of a proscribed sect, he sought confirmation that this was the policy of the central government.

Pliny's letters introduce many of the leading figures of Roman society in the 12 years after the death of Domitian—men of letters, politicians, administrators, generals and rising young men of rank. They make possible the social reconstruction of an age for which there is otherwise no serious historical record. He was an adept at brief character sketches, less satirical, more kindly and possibly more complete than those of Tacitus. His portrait of the learned lawyer Titius Aristo is typical (i, 22, 1–3). He was also a devotee of literature. He has left a detailed picture of the amateur literary world of his time, and of the salons in which it was the custom to recite one's work and to seek critical revision from one's friends.

Pliny published his forensic and literary speeches with loving care, and late in life took to the contemporary fashion for light verse in the style of Martial, at which his samples show that he was no adept. Though fulsome in the praise of contemporary writers, his judgment of the dead Statius was fair: "he was ever writing poems with greater pains than ability." His letters addressed to his fellow advocate Tacitus (*q.v.*), then occupied with his first major work, tell the little that is known about the date and circumstances of the composition of the *Historiae*, to which Pliny contributed his famous account of the eruption of Vesuvius. The biographer Suetonius was among his *protégés*.

A seldom noticed aspect of Pliny's mentality is his semiscientific interest in natural phenomena, which he shared with his uncle, author of the *Naturalis Historia*. Four long letters describe with careful accuracy the peculiar behaviour of subterranean springs, the course of the Vesuvian eruption and the floating islets of the Vadimonian lake (iv, 30; vi, 16, 20; viii, 20). His speculations about their causes are rational. His discussion of dreams and visions has the same quality (vii, 27). His description of external scenery, whether natural or artificial, is remarkably precise, with an exact sense of detail, despite an elaborate literary style.

Style as an Orator.—Pliny's grand oratorical style is known from his panegyric, delivered in the senate when he entered office as consul. This is elaborately antithetical, colourful in ornament, inflated in substance, passionate and violent in tone, and contrasts with the delicacy and balance of the letters. In it he contrasts the merits of the new emperor Trajan with the vices of Domitian, in a most partial manner, but still provides a valuable historical account of Trajan's succession and the first phase of his reign. Pliny's normal forensic manner was probably a great deal quieter and more argumentative, as in viii, 14. He debates the "battle of styles" in several letters.

BIBLIOGRAPHY.—The best modern editions of the letters and of the panegyric of Trajan are those in the "Teubner Series," by M. Schuster, 2nd ed. (1952) and in the "Budé Series," vol. i–iii, by A.-M. Guillemin (1927–43), vol. iv by M. Dury (1947). See the Eng. trans. by W. Melmoth, *The Letters of Pliny the Consul* (1746), rev. by W. M. Hutchinson, "Loeb Series," 2 vol. (1915). There are no modern general commentaries except E. G. Hardy, *Plinii epistulae ad Traianum* (1889); M. Dury, *Panegyrique de Trajan* (1938). See also (for Pliny's life and chronology) T. Mommsen, *Gesammelte Schriften*, vol. iv (1906), pp. 366 ff.; A. N. Sherwin-White, "Pliny's Praetorship Again," in *Journal of the Royal Society*, pp. 126 ff. (1957); R. Syme, *Tacitus*, ch. vii–viii (1958); (for Pliny and literature) A.-M. Guillemin, *Pliny et la vie littéraire de son temps* (1929) (A. N. S.-W.).

PLIOCENE (from Gr. *pleion*, "more," and *kainos*, "recent"), the geological epoch immediately preceding the Glacial (Pleistocene) epoch as indicated on the accompanying geologic time chart. Many modern genera appeared before the epoch was over.

The name Pliocene was introduced by Sir Charles Lyell (1830, published 1833) for the youngest of his three divisions of the Tertiary (*q.v.*) period of time. Lyell initially recognized a "Newer" and an "Older Pliocene." In 1839 he substituted the name "Pleistocene" for "Newer Pliocene," restricting the "Pliocene" to "the formations of Tuscany, and of the Sub-Apennine hills in the north of Italy, as also the English Crag." In 1846 Edward Forbes redefined the Pleistocene, making it equivalent to the time interval of continental glaciation in Europe. This was considered

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	Began (Millions of Years Ago)
CENOZOIC ERA			
Quaternary	Recent (last 11,000 years)		
	Pleistocene	Early man	24
Tertiary	Pliocene	Large armvores	10
	Miocene	Whales, apes, grazing forms	27
	Oligocene	Large browsing mammals	38
	Eocene	Rise of flowering plants	55
	Paleocene	First parental mammals	65-70
MESOZOIC ERA			
Cretaceous		Extinction of dinosaurs	130
Jurassic		Dinosaurs, zenith, primitive birds, first small mammals	180
Triassic		Appearance of dinosaurs	225
PALEOZOIC ERA			
Permian		Reptiles developed, conifers abundant	260
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	300
Lower (Mississippian)		Sharks abundant	340
Devonian		Amphibians appeared, fishes abundant	405
Silurian		Earliest land plants and animals	435
Ordovician		First primitive fishes	480
Cambrian		Marine invertebrates	550-570
PRECAMBRIAN TIME			
		Few fossils	more than 3,490

to have begun somewhat later than was originally envisaged by Lyell and resulted in controversy as to the age of strata falling between the Pliocene as defined by Lyell and the Pleistocene as described by Forbes. During the 18th International Geological congress, in 1948, discussion of criteria for definition of the Pliocene-Pleistocene boundary indicated that the beginning of the Glacial epoch occurred earlier than previously recognized. The boundary has been placed at the original Lyell horizon.

Miocene-Pliocene Boundary.—Type sections of the Lyellian epochs do not occur in the same region. Deposits in many areas of the world cannot exactly be correlated with the Lyell units but are intermediate in position. The problem of the Miocene-Pliocene boundary, for example, has become complex. Vertebrate-bearing Sarmatian and Pontian strata of eastern Europe are not represented in the type sections of either epoch. Vertebrate paleontologists consider the advent of *Hipparion*, a primitive horse found in North America, Europe, Asia and Africa, as marking the beginning of the Pliocene. This genus first occurs in Pontian faunas; hence they are recognized as basal Pliocene. Correlative marine faunas are of distinctive Miocene aspect; invertebrate paleontologists assign the containing strata to the Upper Miocene (*q.v.*), which is the classification used in this article.

PHYSICAL HISTORY

The Miocene epoch closed with a widespread marine regression and consequent development of continental deposits. The expanded Black Sea and Caspian basins, cut off from the Tethyan (ancestral Mediterranean) sea, became brackish water bodies that persisted through the Pliocene. The marine life trapped in these basins underwent striking evolutionary changes.

The Pliocene began with a marine transgression and closed with a regression. In the Sub-Apennine area of Italy, considered as the type area of the epoch, the transgressive phase is represented by blue marls with offshore faunas. These pass upward into yellow sands with littoral faunas regarded as regressive deposits. Above are intertonguing marine (Calabrian) and nonmarine (Villafranchian) strata that, prior to 1948, were assigned to the Upper Pliocene. Much of Italy was flooded by Pliocene seas but small gulfs in the mouths of the larger river valleys characterize most of the Mediterranean Pliocene.

Embayments from the North sea covered Belgium and eastern England. Lower strata have a fauna of warm water affinities indicating a seaway opening toward the south. The deposits in England include the Coralline Crag (crag = shell sand) remarkable for the abundance of bryozoans, formerly identified as coral. The overlying Red Crag of Sussex has a cold water fauna suggesting that the southerly connection had closed.

In eastern Europe large fresh-water lakes formed. Most im-

portant were: (1) the Pannonian lake covering the Hungarian plains; (2) the Dacian lake, separated from the Pannonian by the Carpathian mountains, covering the lower Danubian plains; (3) the Aegean lake occupying the area of the Sea of Marmora, most of the Aegean sea, and parts of Greece and Thrace.

Marine Pliocene deposits in eastern North America are confined to peninsular Florida (Caloosahatchie formation) and coastal South Carolina and southern North Carolina (Waccama formation). The thickest known marine Pliocene, however, occurs in southern California where more than 13,000 ft. of sediments are found in the Ventura basin. Local embayments occurred from Lower California to Alaska.

Occasional mammalian teeth in the shallow water marine formations aid in correlating the marine and nonmarine strata of California. The Thousand Creek formation of Nevada and the Rattlesnake beds of Oregon are of Pliocene age, as is the upper part of the Ogallala group of the high plains; the lower part is correlated with the Pontian stage. These sandy deposits contain seeds of grasses and herbs, bones and teeth of grazing mammals, and leaves of poplar, willow, hackberry, elm and other trees that grew along stream valleys.

In Texas the first appearance of large ground sloths (*Megalonyx*), migrants from South America, testifies to the re-establishment of the connection between the two continents.

Pliocene deposits are not extensive in South America. In Argentina continental Hermoso beds of the Pampas, and the Tunuyan and Araucanian deposits of the Andean foothills yield mammalian remains. Marine faunas occur in the Mancora and Sechura formations of northwestern Peru.

In Japan, marine deposits are widespread but thin and discontinuous due to deposition in small gulfs. An exception occurs in the Yezo-Karafuto geosyncline bordering the Japan sea in northern Honshu island. Here a thick sequence of Miocene-Pliocene strata has no evidence of stratigraphic break between the two epochs. Elsewhere a major hiatus is evident.

Many Pacific islands show raised reefs and reef limestones that are believed to be of Pliocene age. There are also areas of local embayment, as in the Cagayan valley of northern Luzon and the Iloilo basin of Panay, in the Philippines, where clastic sediments represent marine transgressions. In New Zealand Pliocene sediments occur only along the coast of South Island, but an embayment or strait transected North Island in the Napier Bay-Wanganui area. Noteworthy is the fact that whereas the Lower Pliocene faunas are of colder water facies than those of the Miocene, the Upper Pliocene (Castlecliffian) Mollusca indicate warmer waters. This trend which continued into the Pleistocene is interpreted as resulting from the shifting of oceanic currents caused by Late Pliocene diastrophism in the Pacific basin.

Continental deposits of Pontian age are widely distributed in Asia; true Pliocene deposits, however, occur only in the Nagri and Dhok Pathan formations of the Siwalik series of northern India, and at a few poorly known localities in China.

Volcanism.—The volcanic Massif Central of France was initiated as early as Oligocene time, but the first well-dated flows are of Upper Miocene (Pontian) age. During the Pliocene, however, the great volcanoes of Cantal and Mont-Dore grew to elevations comparable to Mt. Etna. Ash and lava flows, 1,000 m. in thickness entomb Lower Pliocene plants and insects. Activity continuing into Villafranchian time culminated in basalt flows that form the present Massif surface.

Tertiary volcanism in North America occurred mainly during the Miocene epoch, but in many areas eruptions continued throughout Pliocene time.

PLIOCENE LIFE

Marine Life.—Marine mollusks show a predominance of recent species. Notable is the trend toward cooler water conditions than are evidenced by Miocene life. The only major exception is in New Zealand. Marine mammals reached their maximum development in the Miocene seas. Many genera became extinct at the end of that epoch, but nearly all families persisted, in reduced numbers, into the recent. Pliocene additions are the orqual

(Balaenopteridae) and the right whales (Balaenidae).

Continental Life.—The Pliocene mammalian fauna of the northern hemisphere is of modern aspect with the majority of the families represented still being extant. A limited amount of faunal exchange took place between Eurasia and North America during Pontian time at the end of the Miocene, but there is little to suggest a connection during the Pliocene itself. No representatives of the Bovidae (cattle, bison, antelope, etc.) or of the Cervidae (deer), families of Eurasian origin, were in the North American fauna. Their place was taken by antilocaprids, related to the pronghorn. *Hyp hippus*, a long-necked, long-bodied, short-limbed, forest horse, and *Hipparion*, a three-toed horse, reached Europe during the Upper Miocene and are present in Eurasia and North America during the Pliocene; typical North American Pliocene horses including *Pliohippus*, ancestor of *Equus*, did not reach the old world. (See also EQUIDAE.)

Characteristic North American Pliocene mammals include camels (*Pliauchenia*, *Procamelus*); hornless rhinoceroses (*Aphelops*, *Peraceras*); short-legged, hippopotamuslike rhinoceros, *Teloceras*; beavers (*Castor*, *Dipoides*); large cats (*Felis*) and sabretooths (*Machairodus*); proboscideans, including *Tetralophodon*, shovel-tusked *Amebelodon*, and mastodons; and many others.

Eurasian faunas are strikingly like those of modern Africa. Bovids include cattle, bison, sheep and goatlike forms and many genera of antelopes. Deer, including *Cervus*, flourished, along with abundant suids and, in Asia, varied giraffids. Proboscideans include the peculiar *Dinotherium* with recurved lower jaw tusks, *Stegodon*, an ancestral elephant, and *Mastodon*. Among the Primates are the monkeys *Macacus* and *Cercopithecus*, and the apes *Dryopithecus* and *Pliopithecus* in Europe, and a larger number of genera in Asia.

Floras.—Pliocene floras are, generically, almost identical with those of today. Distributional differences reflect differing climatic conditions that obtained during the epoch. Unusual is the flora of England, dominated by a mixture of Japanese and North American forms with some Himalayan and Indo-Malayan types. See also PALEOBOTANY; PALEONTOLOGY; also references under "Pliocene" in the Index.

PLOCK, a town in the Warsaw *województwo* (province) of Poland, and seat of a Roman Catholic bishopric, lies on the Vistula, 121 km. (75 mi.) WNW of Warsaw. Pop. (1960) 42,000. In summer it is a stop for river passenger traffic between Warsaw and Danzig. It is a picturesque town built high above the Vistula; its many old buildings include the 12th-century cathedral, restored in various styles and containing the tombs of several Polish kings. The town is on the Kutno-Sierpc railway and on secondary roads. It has food and metal industries. In the 1960s industrial development included the construction of a huge oil refinery and chemical plants, fed by a pipeline bringing the crude petroleum from Bashkiria, U.S.S.R.

Plock is one of the oldest settlements in Mazovia and was important in the 11th century. It was the capital of the Plock principality when the Polish state was divided into smaller kingdoms. After the second partition of Poland in 1793 it passed to Prussia. From 1807 to 1815 it was in the duchy of Warsaw, and was then incorporated in the Polish kingdom, dependent on Russia. It returned to Poland in 1918. During World War II, under administration of East Prussia, Plock was called Schröttersburg.

(T. K. W.)

PLOEȘTI, administrative centre of the Rumanian *regiune* (administrative and economic region) of the same name, is situated between the valleys of the Prahova and Teleajen, 60 km. (37 mi.) N of Bucharest by road. Pop. (1960 est.) 125,724. It was founded as a market town in 1596 on the site of the village of Ploesti by Michael the Brave (Mihai Viteazul), prince of Walachia,

and its industrial development began with the exploitation of oil in the 19th century. It was severely bombed by the Allies during World War II. Ploesti is the main centre of the Rumanian petroleum industry, having oil refineries and storage installations, and factories producing petroleum equipment; it also produces chemicals, building materials, textiles, clothing, and leatherware. Ploesti is also a cultural centre, with state theatre, puppet theatre, state philharmonic orchestra, and regional museum.

PLOEȘTI REGIUNE, in northeastern Walachia, lies between the Dimbovița Valley to the west and the Râmnic Valley to the east, touching the Carpathian peaks in the north and the valley of the Ialomița in the south. The region includes the Bucegi Mountains (Mt. Omul, 8,228 ft. [2,508 m.]), the Buzăului Mountains, sub-Carpathian hills and valleys, and part of the Rumanian Plain. One-third of the region is covered with forests, and an equal area is arable land on which grain, sunflowers, and sugar beets are grown. There are also famous vineyards (Valea Călugărească, Istrița de Jos, Dealu Mare), fruit-growing centres (Vălenii de Munte, Pucioasa), and market gardens; and sheep, horned cattle, and poultry are raised in large numbers. Ploesti is the chief industrial region of Rumania, the most important branch being the petroleum industry. Oil is extracted in the Prahova, Dimbovița, and Buzău (Buzăul) valleys; there are refineries at Ploesti town, Cimpina, Baicoi, Teleajen-Cheia, and Brazii de Sus; combustible shale is exploited at Breaza and Pucioasa; and petroleum equipment is manufactured and sent all over the world. About two-fifths of the country's salt output is extracted at Slănic, and sulfur and building materials are also produced. Other industries are engineering and chemicals. Besides Ploesti, the chief towns (pop. 1960 est.) are Buzău (51,075), Tirgoviste (26,671), Cimpina (20,733), Râmnicu Sărat (20,696), Sinaia (9,917), Urlați (8,871), Mizil (7,788).

PLOTINUS (A.D. 205–270) was the founder and incomparably the greatest philosopher of the Neoplatonist school (see NEO-PLATONISM). There is a good deal of reliable information about his life; as his pupil and editor Porphyry wrote his master's biography as an introduction to his edition of the works of Plotinus, the *Enneads* (it appears at the beginning of all complete manuscripts of the *Enneads* and is printed in the same place in all editions). But Plotinus himself would never say anything about his family or birthplace, and it is not known for certain to what race or country he belonged, though it is generally assumed, on the strength of a statement of rather doubtful reliability in Eunapius, that he came from upper Egypt. He was certainly Greek by education and cultural background. He studied philosophy at Alexandria, where he could find no teacher to satisfy him till someone introduced him to the mysterious Ammonius Saccas (q.v.), with whom he remained for 11 years. He went east in 243 with the emperor Gordian III's expedition, in the hope of studying Persian and Indian philosophy. But Gordian was murdered in Mesopotamia in 244, and Plotinus escaped to Antioch without having made any contact with eastern thinkers. In the same year he went to Rome, where he spent the rest of his life teaching philosophy and, after ten years, began to write. This is the period when he is known best from Porphyry's biography, where he appears not only as a great teacher and spiritual director but also as a man of great charm and of far-reaching and efficient practical kindness. He died in his 66th year, after a long and painful illness (probably a form of leprosy) which he bore most bravely. His writings were collected and published by Porphyry in the rather artificial arrangement known as the *Enneads*; but Porphyry also kept and published in his biography a record of the chronological order in which they were written, which is followed in some modern editions.

The importance of Plotinus in the history of European thought is very great indeed. For more than two centuries before his time a revived Platonism, much influenced by Aristotelianism and by the Stoics, had been developing. But it was Plotinus, a philosophical genius of the first order and at the same time a man of deep contemplative religion and one of the world's greatest mystical writers, who made this new Platonism into one of the great religious philosophies. The success of Neoplatonism was rapid. Soon after Plotinus' death it came to dominate the Greek philo-

sophical world completely. It deeply influenced, too, the new intellectual world of the great Christian thinkers. It is true that the beginnings of Christian Platonism go back beyond Plotinus and that the great Christian Platonists were more original and independent—and indeed more thoroughly Christian—thinkers than has sometimes been supposed and so must not be represented as merely passive recipients of the influence of Plotinus and his school. Nevertheless that influence did go very deep with many of the Christian Fathers, notably with St. Augustine in the west and with the great Cappadocians, St. Basil and St. Gregory of Nyssa, in the east; and, later, the enigmatic but extremely influential Pseudo-Dionysius (*see* DIONYSIUS) the Areopagite was much influenced by Neoplatonism. Plotinus, through these and other intermediaries, had a great indirect influence on the thought of the Middle Ages and both a direct (after the publication of Marsilio Ficino's Latin translation in 1492) and an indirect influence on the Renaissance; and his philosophy, still living and actual in the 20th century, seems likely to continue to be so, for his writings have in them an unusual power to inspire a new outlook on the world, to raise men's minds to the eternal and to encourage a moral virility very valuable in precarious times.

Philosophy.—Like other philosophers of the Hellenistic and Roman periods, Plotinus is a religious and moral teacher as well as a professional philosopher engaged in the critical interpretation of a long and complicated school tradition. He is an acute critic and a formidable arguer, with the intellectual honesty of a true philosopher; but philosophy for him is not primarily a matter of abstract speculation, or critical discussion of language or concepts, but a way of life in which, through an exacting intellectual and moral self-discipline and purification, those who are capable of the ascent can return to the source from which they came. His philosophy is an account of how from the eternal creative act, at once spontaneous and necessary, of that transcendent source, the One or the Good, proceeds a world of living reality constituted by repeated double movements of outgoing and return in contemplation; and this account, showing the way for the human self, which can experience and be active on every level of being, to return to the One, is itself an exhortation to follow that way.

Plotinus always insists that the One or the Good is beyond the reach of thought or language; what he says about this supreme principle is only intended to point the mind along the way to it, not to describe or to define it. But though no adequate concept or positive definition of the Good is possible, it is certainly not for Plotinus a mere negation or ultimate void in attaining to which the human personality disintegrates into unconscious nothingness. It is a positive reality of infinite richness and superabundant excellence. Plotinus often speaks of it in extremely negative language—largely inherited from the Platonic school tradition. But his object in doing so is to stress the inadequacy of all our ways of thinking and speaking to express this supreme reality, or to make clear the implications of saying that the Good is absolutely one and infinite and the source of all defined and limited realities.

The original creative act of the One produces the first great derived reality, *nous*, intellect or spirit; from this again comes soul, which forms, orders and maintains in being the material universe. It should be remembered that the generation of this ordered universe is timeless; *nous* is eternal, and time is the life of soul, and there was never a time when the material universe did not exist. Also we must remember that the "levels of being" are not spatially separate or cut off from each other. They are really distinct, but all intimately present in every part of the universe and in each one of us. To ascend through soul to intellect and from intellect to the One we do not have to travel in space to another world, but must wake to a new kind of awareness.

Intellect for Plotinus is both thought and object of thought; it is a mind which is perfectly one with its object. As object, it is the world of forms or ideas, the totality of real being in the Platonic sense. These forms are produced by intellect's apprehension in multiplicity of the rich unity of its principle, the One; and, being one with intellect, they are not merely static objects but living, thinking subjects, each not only itself but capable in contemplation of becoming the whole. They are archetypes

and causes of the necessarily imperfect realities on lower levels, souls and the forms in body. We, at our highest, are intellects, or souls perfectly conformed to intellect; we become aware of our intellectual nature when, passing beyond not only sense perception but also the discursive reasoning characteristic of the life of soul, we attain to an intuitive contact and immediate possession of eternal realities.

Soul in Plotinus is very much what it is in Plato, the intermediary between the worlds of intellect and sense and the representative of the former in the latter. It is produced by intellect, as intellect is by the One, by a double movement of outgoing and return in contemplation, but the relationship between the two is more intimate and the frontier less clearly defined. For Plotinus, as for Plato, the characteristic of the life of the soul is movement, and this soul movement is the cause of all other movements. Soul, unlike intellect, does not possess being as a whole, one with itself in immediate awareness; it is on the level, as already mentioned, of discursive thought which does not grasp its object immediately but has to seek it by a process of reasoning. The life of the soul in this movement is time, and on it all physical movement depends. Soul in relation to the material universe exists on two levels, a higher and a lower. The higher, in close and unbroken touch with intellect, forms and rules the material universe from above; the lower, which Plotinus often calls nature, acts as an immanent principle of life and growth and in its dream-like contemplation, the last and lowest of contemplations, produces the immanent forms in body, which are noncontemplative and so sterile. Below these lies the darkness of matter, the absolute limit, the final absence of being at which the expansion of the universe from the One through diminishing degrees of reality and increasing degrees of multiplicity comes to an end. Because of its utter negativity, matter (at least the matter of the lower regions of the sense world) is for Plotinus the principle of evil; and his language about it has a strongly dualistic flavour. His real thought, however, does not seem to be genuinely dualistic, but he strongly maintained against the Gnostic dualists of his time the goodness and nobility of the physical universe as the best possible work of soul; in this he was faithful to the teaching of Plato in his later dialogues, as expressed most impressively and influentially in the *Timaeus* (*see* PLATO: *Later Dialogues*).

We, as souls in bodies, can exist on any level of the soul's experience and activity. (Our descent into bodies is for Plotinus, who has some difficulty in reconciling Plato's various statements on this point, both a fall and a necessary compliance with universal law.) We can ascend in spirit to the level of universal soul, become that whole which we already are potentially and, in soul, attain to intellect; or we can isolate ourselves on the lower level, shutting ourselves up in the experiences, desires and concerns of the lower nature to which we are attached and remaining ignorant of any higher kind of awareness than that of the senses. Philosophical conversion, the beginning of the ascent to the One, consists precisely in turning away from the life of the body, dominating and rising above its desires and "waking to another way of seeing, which everyone has but few use." This, Plotinus insists, is possible while we are still in an earthly body and without neglecting the duties of our embodied state. But the body and bodily life are things which weigh us down and hamper us in our ascent; Plotinus' language when speaking of it in this connection is strongly dualistic and other-worldly. In this he follows Plato in the *Phaedo*, but it is not impossible that he was unconsciously influenced by the Gnosticism that he consciously opposed.

The material universe for Plotinus is a living organic whole. Its organic wholeness is the best possible reflection on the material level of the living unity-in-diversity of the world of forms in intellect. It is held together in every part by a universal sympathy and harmony (a belief in which, deriving both from Stoic philosophy and from some very primitive conceptions, Plotinus shared with contemporary magicians and occultists). In this harmony external evil and suffering take their place as necessary elements in the great pattern, the great dance of the universe.

Evil and suffering can affect our lower selves but cannot touch our true, higher selves and so cannot interfere with the real well-being of the philosopher who chooses to live on that higher level.

From what has been said so far something of the nature of Plotinus' religion should have become clear. It is essentially the effort to actualize in ourselves the great impulse of return to the Good which constitutes reality on all its levels. By a rigorous moral and intellectual self-discipline we awake from the alienation of our lower state and rediscover our true selves. We become intellect and then, when the One manifests to us his continual presence, we rise to the mystical union, carried on the surge of the current of the impulse of return in its strongest and final flow, the pure love of intellect for its source. There is no consciousness of duality in that union; we are not aware of ourselves; but we are not destroyed or dissolved into the One because even in the union we are still intellect, though intellect "out of itself," transcending its normal nature and activity. The mystical union was for Plotinus, in this life at any rate, a rare and transitory experience. He attained to it, Porphyry tells us, four times while Porphyry himself was a member of the school. But it was the goal of all his effort and the source of the continuing power of his teaching. Philosophy for him was the way to union with the Good through moral purification and intellectual enlightenment.

See also PHILOSOPHY, HISTORY OF; *Later Greek Philosophy*; and references under "Plotinus" in the Index.

BIBLIOGRAPHY.—The Greek text of the *Enneads* was first printed by P. Perna (1580), together with the Latin translation by Marsilio Ficino, which had already appeared (1492). The best 19th-century edition is by R. Creuzer and G. H. Moser (1835; text reprinted in the Didot edition, 1855); others are by A. Kirchhoff (1856), by H. F. Muller (1878-80) and by R. Volkman (1883-84). The edition of E. Bréhier (1924-38), though the text is poor, is valuable for its admirable notes and introductions to the several treatises. A great critical edition, to supersede all others, was undertaken by P. Henry and H. R. Schwyzler (1951 et seq.).

Plotinus has been translated into most modern European languages. In English there is a complete translation by S. MacKenna and B. S. Page, 2nd ed. rev. (1957), also selecting treatises with introduction and notes by A. H. Armstrong (1953). The French translation by M. N. Bouillet (1857-61) is still valuable for its vast and learned commentary; and there is a version by E. Bréhier (in his edition). The German translation by R. Harder (1930-37; reissue, with text and commentary, 1956 et seq.) and the Italian by V. Cilello (1947-49) are accurate and scholarly.

For a complete bibliography of the vast literature on Plotinus, up to 1949, see B. Marien, *Bibliografia critica degli studi plotiniani* (1949), published with the last volume of Cilello's trans. Only a few works can be mentioned individually here: W. R. Inge, *The Philosophy of Plotinus* (1918; reprint 1948); E. Bréhier, *La Philosophie de Plotin* (1928); A. H. Armstrong, *The Architecture of the Intelligible Universe in the Philosophy of Plotinus* (1940); J. Katz, *Plotinus' Search for the Good* (1950); H. R. Schwyzler, "Plotinus," in Pauly-Wissowa, *Real-Encyclopädie der klassischen Altertumswissenschaft*, vol. xxi (1951); M. de Gandillac, *La Sagesse de Plotin* (1952); J. Trouillard, *La Procession plotinienne et La Purification plotinienne* (1953); H. Fischer, *Die Aktualität Plotins* (1956). (A. H. AO.)

PLOUGH (PLOW); see TILLAGE MACHINERY.

PLOVDIV, the second largest town of Bulgaria and the chief town of Plovdiv okrug (administrative and economic district). It lies on both banks of the Maritsa River, 99 mi. (160 km.) ESE of Sofia by rail. Pop. (1961 est.) 188,758, of whom about 90% are Bulgars and the remainder mostly Turks, Armenians, Jews, and gypsies. The town is picturesquely situated on and around six syenite hills rising from the western Thracian Plain, with distant views of the Balkan and Rhodope (Rodopi) mountain ranges. In the old quarter, Trimontium (see below), built on three of the hills, parts of the Roman walls remain, and there are original old houses with characteristic overhanging upper stories. The main thoroughfare of the modern town is Vasil Kolarov Street. Educational and cultural institutions include schools of medicine and of agriculture, a theatre, an opera house, an ethnographic museum, and an archaeological museum containing a collection of ancient Thracian gold vessels. The town is a railway junction on the Belgrade-Sofia-Istanbul line and has an airport. The chief market of a fertile region, producing tobacco, rice, vegetables, and fruit (including grapes), it has important

tobacco, food-processing; and textile industries; also motor repair works, a shoe factory, and a lead and zinc works. An international trade fair is held biennially.

Within the district, 11 mi. (18 km.) SE of Plovdiv is Ase-novgrad (Stanimaka), also an industrial centre. Nearby are ruins of a fortress built by Tsar Ivan Asen II (1218-41), and, about 7 mi. (11 km.) distant, the 11th-century monastery of Bachkovo.

Plovdiv was called Pulpudeva in Thracian times. It was re-named Philippopolis in 341 B.C., after conquest by Philip II of Macedonia. Under the Romans (from A.D. 46) it became the capital of the Thracian province, with the name of Trimontium. It was repeatedly sacked by Goths and Huns and changed hands many times during the Middle Ages. In 1364 it was taken by the Turks, who called it Philibé. After the Russo-Turkish War of 1877-78 it became the capital of the autonomous Turkish province of Eastern Rumelia, which united with Bulgaria in 1885.

PLOVDIV OKRUG is one of 28 major administrative and economic districts (including the urban district of Sofia) into which the country was divided in 1964, when the cities of Plovdiv and Varna lost the status of centrally administered urban districts which they had held since 1959 (see also BULGARIA: *Administration and Social Conditions*). Area 2,145 sq.mi. (5,556 sq.km.). Pop. (1962 est.) 610,800.

The district stretches across the Thracian Plain from the Rhodopes in the south to the Balkan Mountains, whose highest peak, Botev, is on the northern boundary. In the north, around Vazovgrad, Levskigrad, and Kolofer, roses are cultivated for the distillation of attar. (L. Dt.)

PLOVER, the name for many plump-breasted birds of the shorebird family (Charadriidae), which also includes surfbirds, turnstones, and lapwings. There are about three dozen species of plovers, 6 to 12 in. long, with long wings, moderately long legs, short necks, and straight bills that are shorter than the head. Many species are plain brown, gray, or sandy above and whitish below. The group of so-called ringed plovers (certain *Charadrius* species) have white foreheads, one or two black bands ("rings") across the breast, and occasional other bold markings. Some plovers, like the golden (*Pluvialis* species) and black-bellied (*Squatarola squatarola*), are finely patterned dark and light above and black below in breeding dress.

Many plovers feed by running along beaches and shorelines, snapping up small aquatic invertebrate animals for food. Others, like the killdeer (q.v.), of upland meadows and grasslands, are chiefly insectivorous. Plovers and their relatives are wary birds, quick to give alarm. When flushed, they take swift and direct flight. Many utter melodious whistled calls, which can be used to distinguish the species. Plovers nest in a slight hollow in the ground where two to five (usually four) spotted eggs are laid. Both parents help incubate and care for the downy young, which soon after hatching run about and accompany their parents.

Plovers are found in most parts of the world. Those nesting

BLACK-BELLIED PLOVER (*SQUATAROLA SQUATAROLA*) SHOWING (LEFT) FALL AND (RIGHT) SPRING PLUMAGE

in the north are strongly migratory and like to travel and feed in flocks. Most notable as long-range migrants are the golden plovers—the American (*Pluvialis dominica*) and the Eurasian (*P. apricaria*)—which breed in the Arctic and winter in the Southern Hemisphere, often far south of the Equator. The American golden plovers of the eastern range fly over the Atlantic and South America as far south as Patagonia, and most return via the Mississippi Valley; those in the western range travel, presumably non-stop, to groups of islands in the South Pacific. The Eurasian golden plovers winter in South Africa, Tasmania, and New Zealand.

(A. L. RD.)

PLÜCKER, JULIUS (1801–1868), German mathematician and physicist, best known as an analytic geometer, but also carried out important research in magnetism and spectroscopy. He was born at Elberfeld on June 16, 1801. After studying at the universities of Bonn, Heidelberg, and Berlin he went in 1823 to study in Paris, where he came under the influence of the great school of French geometers whose founder, Gaspard Monge, had only recently died. In 1825 he was received as *Privatdozent* (official but unpaid lecturer) at Bonn, and after three years he was made professor extraordinary. He then held the following posts: professor of mathematics at Friedrich Wilhelm's *Gymnasium*, Berlin (1833–34), professor of mathematics at Halle (1834–36), professor of mathematics (1836–47) and finally professor of physics (1847) at Bonn. He died at Bonn on May 22, 1868.

From his lectures at Bonn sprang his first great work, *Analytisch-geometrische Entwicklungen*, 2 vol. (1828–31), in which he introduced the abridged notation in analytical geometry. (See ANALYTIC GEOMETRY.) He applied this notation to the straight line, circle, and conic sections, and he used it in his theory of cubic curves. Also he established the great principle of duality. He discovered the six equations known as "Plücker's equations" connecting the numbers of singularities in algebraical curves. (See CURVES.) Plücker communicated his formulas in the first place to *Crelle's Journal*, vol. xii (1834) and gave a further extension and complete account of his theory in his *Theorie der algebraischen Curven* (1839). In his *System der analytischen Geometrie* (1835) he introduced the use of linear functions in place of the ordinary co-ordinates; he also made the fullest use of the principles of collineation and reciprocity. He discussed curves of the third order and gave a complete enumeration of them, including 219 species. In 1846 Plücker published his *System der Geometrie des Raumes in neuer analytischer Behandlungsweise*, but this contains merely a more systematic and polished rendering of his earlier results.

After his appointment as professor of physics at Bonn, Plücker began a series of researches in physics. His first physical memoir, published in J. C. Poggendorff's *Annalen der Physik und Chemie* (1847), deals with the behaviour of crystals in a magnetic field. Then followed a long series of researches, mostly published in the same journal, on the properties of magnetic and diamagnetic bodies, establishing results which are now part and parcel of our magnetic knowledge. This was followed by researches on the discharge tube; he investigated the deflection of the discharge by a magnet and the behaviour of the negative glow in a magnetic field. Plücker, first by himself and afterward in conjunction with J. W. Hittorf, made many important discoveries in the spectroscopy of gases. He anticipated R. Bunsen and G. R. Kirchhoff in announcing that the lines of the spectrum were characteristic of the chemical substance which emitted them and in indicating the value of this discovery in chemical analysis. According to Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances, and thus solved one of the mysteries of modern astronomy. Induced by his mathematical friends in England Plücker in 1865 returned to "line geometry." His first memoir on the subject was published in the *Philosophical Transactions* of the Royal Society in 1865. Plücker worked out the theory of complexes of the first and second order introducing in his investigation of the latter the famous complex surfaces of which he caused those models to be constructed which are now well known to the student of higher mathematics. He left an

uncompleted work on the subject which was so far advanced that his pupil and assistant, Felix Klein, was able to complete and publish it.

PLUM, a fruit tree belonging to the genus *Prunus* of the rose family (Rosaceae). Like the peach and cherry, also members of the same genus, it is a stone or drupe fruit. Plums are the most widely distributed of the stone fruits. The fruit is also grown over a wide region in Europe from Italy on the south to Norway and Sweden on the north. Yugoslavia is the leading country with a

tree potential of more than a million tons' production. A liqueur called *Slivovica* made from plums is an important article of commerce in Yugoslavia. Germany is the next largest producer of plums in Europe with a tree potential that in some years has equaled that of the U.S. in production. Turkey and Japan are leading countries in plum production in Asia.

It is not known just when European plums were introduced into North America, but probably pits were brought over by the first colonists. It is reported that plums were planted by the Pilgrims in Massachusetts and

ROCHE
PLUM BLOSSOMS

importations were made by the French into Canada. These European plums have done remarkably well in the new world, and they constitute the most important group grown commercially for canning and drying.

Plant Characteristics.—The trees of some plum species are vigorous in growth with upright branches reaching a height of 20–30 ft., while others are much smaller; some are small shrubs with drooping branches, and some have great beauty as ornamental plants. The flower buds on most varieties and species are borne on short spurs or along the terminal shoots of the main branches. Each bud may contain from one to five flowers, two or three being most common; and where the buds are close together, they give an appearance of densely packed, showy flower clusters when the trees are in full bloom. Characteristic of the genus *Prunus*, the individual flower is made up of a receptacle forming a hollow cup bearing sepals, petals and stamens on the outer rim surrounding a single pistil attached at the bottom of the cup. After fertilization of the flower, the receptacle and attachments fall off and the style withers and drops off, leaving the enlarged basal portion of the pistil, the ovary, which develops into the fruit.

The fruit of the plum develops from a single ovary. As the fruit grows to maturity, the outer part of the ovary ripens into a fleshy, juicy exterior making up the edible part of the fruit and a hard interior called the stone or pit. The seed is enclosed within the stone. The fruits show a wide range of size, flavour, colour and texture.

Species.—The common European plum, known botanically as *Prunus domestica*, appears to have originated somewhere in southeastern Europe or western Asia, probably in the region around the Caucasus and the Caspian Sea. Although it is called the European plum, some botanists who have summarized the history of these stone fruits are doubtful that *P. domestica* is indigenous to Europe. According to the earliest writings in which this plum is mentioned, the species dates back about 2,000 years.

Another old world plum species, probably of European or Asiatic origin, is the damson plum (*P. insititia*). This species seems to antedate *P. domestica*, as is suggested by the finding of damson plum pits in ancient ruins. The ancient writings connect the early cultivation of these plums with the region around Damascus.

An important species native to China is the plum (*P. salicina*), which was domesticated in Japan and was introduced into the United States about 1870.

Two less important species are the myrobalan plum (*P. cerasifera*), a native of Europe, and the Simon or apricot plum (*P.*

simonii), a native of China. The myrobalan plum has been used a great deal in the United States as a rootstock. Varieties of *P. cerasifera* and *P. simonii* are noted for their ornamental foliage.

Botanists have divided the native American plums into a number of species and subspecies. Many of them have numerous characteristics in common, so that they overlap somewhat in horticultural groups and classifications. *P. americana*, the most important of the native species, has a wide range of adaptation in the United States, extending from Maine to Florida, westward to Utah, and northwestward into Manitoba. The tree is small, not so vigorous as the European, and it has rough, shaggy, grayish bark. The fruit is red, reddish-yellow, or reddish-orange, possesses a pleasant flavour and is of good quality, but it has a thick, tough skin and the flesh clings to the pit. Desoto and Weaver are among the typical cultivated varieties of americanas.

Other American species of minor importance from a commercial standpoint but of interest to the fruit breeder are the native varieties of *P. hortulana*, the chickasaw plum (*P. angustifolia*), and the wildgoose plum (*P. munsoniana*) of the southeastern and south central United States, of which Wildgoose and Robinson are important varieties.

Still other species of plums growing in North America are the Canada plum (*P. nigra*), which is adapted to the north central United States and Canada; the small beach plum (*P. maritima*), which grows along the eastern seacoast; and the western or Pacific plum (*P. subcordata*), which grows east of the Coast range in southern Oregon and northern California.

Varieties and Cultivation.—Cultivated varieties of at least 12 species of plums are to be found in U.S. orchards or growing in the wild, but most of the important commercial varieties are confined to four of the species already mentioned, namely, *domestica*, *insititia*, *salicina* and *americana*.

The best known and most important of these groups are varieties of *Prunus domestica*, the European plums and prunes. These are vigorous-growing trees, upright spreading in habit. Unfortunately, they are not well adapted to regions with hot, dry summers or dry, cold winters. They are at home in the northeastern United States and in sheltered sections along the Great Lakes; but they are at their best in the irrigated regions of the intermountain and Pacific coast states, as is evidenced by the extensive production of fresh fruit and dried prunes in this region. The trees do well on medium heavy soils that are well drained. They blossom later than peaches and thus escape spring frosts. The European plums have been under domestication longest, and the fruits are notable for large size and attractive appearance. They vary in colour from the green and golden yellow of the Reine Claude (greengage) and Yellow Egg groups to the red and dark purple of the Lombard and Italian prune.

The damsons (*P. insititia*) of the old world are quite different from the domesticas. The trees are more upright, compact and dwarfish; the leaves and flowers are smaller; and the fruits are small, round and quite tart, so that they are especially suitable for preserves and jams. Varieties of this group are hardy, vigorous and productive, and the trees make good stocks for other species, being adapted to a wide range of conditions and thriving even when they are neglected. The Shropshire and the French are important blue damsons in the United States, while the yellow Mirabelles are popular in France. The demand for varieties of plums of this type is limited, and they are not planted as extensively as those varieties that can be consumed fresh, dried or canned.

The oriental plums (*P. salicina*) are relatively new to North America, but they were widely planted and became second to the domesticas in commercial production. The trees are more spreading in habit than the domesticas or damsons, and in leaf and fruit characters they are very different, resembling the native American plums. The fruits are very attractive and are characterized by a yellow ground colour overlaid by various shades of red. In some varieties the flesh colour is striking red, whereas fruit of the domesticas and damsons is green or yellow. Some newer hybrids of the *salicina* group show distinct superiority in flavour and in commercial possibilities over the early importations. Varieties of

this group appear to be widely adapted in the United States except in the very coldest climates. While the quality is not equal to that of the best domesticas, and the commercial varieties are not so satisfactory for canning and drying, the fresh fruit is delicious in its blend of flavours. The varieties cross readily with one another and with the native americanas. Among the first so-called Japanese plums grown in the United States, Kelsey, Burbank, Abundance and Satsuma are typical. The trees are hardy and productive, and they tolerate a variety of soils as well as climatic conditions. The blossoms open earlier, however, than those of the domesticas and damsons and are frequently killed by spring frosts in the eastern part of the United States.

The native American plums were doubtless used for food by the Indians long before the white man set foot on the shores of North America. Reports of early explorers mention the finding of plums growing in abundance. According to the descriptions of the early settlers, these plums were inferior to the domesticas of the old world in quality, so that the colonists soon began importing varieties from Europe. As a result, European plums soon became predominant in home fruit gardens as well as commercial orchards in the northeastern United States. Varieties of native species, however, while not grown in commercial orchards, do fill a need in supplying fruit for the home garden in regions where the domesticas are not well adapted, as for example in the southwestern and south central United States. American varieties also have been selected for planting in the northern Great Plains where only cold hardy sorts can survive. Varieties like Assiniboin and Cheney of the *P. nigra* group, and Wyant and Desoto of the americanas, survive in this region.

Hybrids produced by crossing American and oriental varieties have given larger fruited varieties of better quality, also adapted

to the colder climates. Waneta and Underwood are two varieties that have been planted in home gardens. Furthermore, American species hybridize with the sand cherry (*P. pumila*), and plant breeders have produced new varieties adapted to cold and dry conditions in the northern Great Plains. Important varieties are Opatá, Sapa and Oka.

In the United States, as well as in Europe, the plum has long been recognized as one of the most delicious of fruits, and among the stone fruits it ranks next to the peach in commercial production. Many of the varieties of plums cultivated in the United States have been introduced from elsewhere, and when these are added to the native varieties they give plums the largest number and greatest diversity of kinds and species among the stone fruits.

Fortunately varieties can be selected that are adapted to a wide variety of soils and climatic conditions. Plums respond to good soil management practices. As trees come into bearing they do not require much pruning and in the home fruit garden can be grown satisfactorily if insects and diseases are controlled.

Insects and Diseases.—The fruit and tree of the plum are attacked by a number of troublesome insects and diseases that seriously limit production if not controlled by spraying. One of the most serious of the insect pests is the plum curculio, a small beetle that deposits its eggs in the fruit. As the larvae hatch and feed on the fruit, the affected fruits drop prematurely. Sometimes all of the fruits will drop off before harvest. This insect can be controlled by timely spraying with arsenate of lead or by the insecticide malathion.

Brown rot caused by a fungus that gains entrance through breaks in the skin or through punctures caused by the curculio may also be a serious menace. Fortunately this disease can be con-

ROCHE

PLUMS (PRUNUS)

trolled by the timely application of fungicides of sulfur or copper. A bacterial leaf disease called bacterial spot, or shot hole, is serious in the more southern latitudes of the United States. Some varieties are quite resistant to this disease while others are susceptible. For the successful production of plums in any region a timely spray program must be followed to protect the fruit and foliage against these insect and disease pests.

Prunes.—Prune is a name given to a plum that can be dried into a firm long-keeping product. This term is frequently applied as a group name to plum varieties that have a sufficiently high sugar content and firm flesh, qualities that favour their being preserved by drying. In California most of the plums are dried in the sun, whereas in Oregon and Washington drying is done in specially built dehydrators, with artificial heat. The growing of plums for the production of prunes in the United States is confined largely to the states of California, Oregon, Washington, and Idaho. Prune d'Agén, Italian, Sugar and Imperial Epineuse, all of European origin, are among the principal varieties in the U.S.

PLUMBAGO: see GRAPHITE.

PLUMBING is the system of pipes and fixtures installed in a building for the distribution of potable (drinkable) water and the removal of water-borne waste materials. A plumbing system should perform in such a manner that the building's occupants are never endangered by contaminated drinking water or by contact with harmful wastes. Safe plumbing systems can only result from careful planning which takes account of the location of the building, the particular conditions arising from the design of the building and the activity taking place within it, the limitations of the municipal water and sewerage systems, and the plumbing standards enforced by the local, state or national governments. Properly designed, a plumbing system will maintain sanitary conditions over a broad range of both normal and abnormal operating conditions.

The piping system installed within a building is usually distinguished from the water and sewerage systems which serve a building, a group of buildings or a city.

The building plumbing system is usually considered to start at the point where the municipal water and sewerage lines cross the property lines of the building, or at some defined point just outside the building.

History.—One of the problems of every civilization in which the population has been centralized in cities and towns has been the development of adequate water and sewerage systems. In certain parts of Europe the complex aqueducts built by the Romans to supply their cities with potable water can still be seen. However, the early systems built for the disposal of human wastes were not quite so elaborate. Human wastes were often transported from the cities in carts or buckets or else discharged into an open, water-filled system of ditches which led from the city to a lake or stream.

Improvement in plumbing systems was very slow. Virtually no progress was made from the time of the Romans until the 19th century. The relatively primitive sanitation facilities were inadequate for the large, crowded population centres which sprang up during the Industrial Revolution, and outbreaks of typhoid fever and dysentery were often spread by the consumption of water contaminated with human wastes. Eventually these epidemics were curbed by the development of separate, underground water and sewage systems which eliminated open sewage ditches. In addition, plumbing fixtures—among them the lavatory basin, bathtub and water closet or toilet—were designed to handle potable water and water-borne wastes within buildings. However, these early fixtures often allowed sewer gases, bacteria and vermin to enter buildings through the open drain pipes with which they were connected to the sewer, and it was not until the latter

part of the 19th century that the siphon water closet and the sanitary fixture trap were widely introduced, although the first patent for a water-sealed trap had been granted a century earlier.

Plumbing Fixtures and Materials.—The term plumbing fixture embraces not only showers, bathtubs, lavatory basins and water closets but also such devices as washing machines, garbage-disposal units, hot-water heaters, dishwashers and drinking fountains.

The materials used in a plumbing system must be strong, non-corrosive and durable enough to equal or exceed the expected life of the building in which they are installed. In addition, the materials used in fixtures that are exposed to view should be attractive and easy to clean.

Water closets, urinals and lavatories usually are made of stable porcelain or vitreous china, although they sometimes are made of glazed cast iron or steel or of stainless steel.

Ordinary water pipes usually are made of steel, copper, brass, lead, plastic or other nontoxic material, while the most common materials for sewerage pipes are cast iron, steel, copper, and asbestos cement.

Special fixtures—and entire plumbing systems of special design—are required for chemical laboratories and for plants manufacturing and processing chemicals and food products. Piping and fixtures for such applications may be made of glass, stainless steel, glass-lined metal, plastic, ceramics or special alloys. Drains often must be of special design to ensure proper disposal of corrosive or toxic materials. In the design of food-processing plants, the criterion is ease of cleaning equipment and piping.

Water-Supply Systems.—Usually only potable water is distributed in the water-supply system, but occasionally separate systems are installed for the distribution of nonpotable water used in industrial processes, fire-fighting equipment, or irrigation.

For towns and cities, municipally or privately owned water companies treat and purify water collected from wells, lakes, rivers and ponds and distribute it to individual buildings.

In rural areas water is commonly obtained directly from individual wells.

In most cities, water is forced through the distribution system by pumps, although in rare instances, when the source of water is located in mountains or hills above a city, the pressure gen-

FIG. 1.—SIMPLIFICATION OF A WATER-SUPPLY SYSTEM, SHOWING HOW WATER PRESSURE AND HEIGHT ARE RELATED

erated by gravity is sufficient to distribute water throughout the system.

In other cases, water is pumped from the collection and purification facilities into elevated storage tanks and then allowed to flow throughout the system by gravity.

However, in most municipalities, water is pumped directly through the system; elevated storage tanks may also be provided to serve as pressure stabilization devices and as an auxiliary source in the event of pump failure or of a catastrophe, such as fire, that might require more water than the pumps or the water source are able to supply. (See WATER SUPPLY AND PURIFICATION.)

The pressure developed in the water-supply system and the friction generated by the water moving through the pipes are the two factors which limit both the height to which water can be distributed and the maximum flow rate available at any point in the system. For example, if no water is drawn from the system in fig. 1, the pressure at any point in the building is equal to the pressure developed by the water tank less the pressure exerted by the column of water in the building below the point where the pressure is being measured.

If water is drawn from the system, the pressure at any point in the building will drop by an amount equal to the pressure required to overcome friction generated by the water moving in the pipes. As more and more fixtures draw water, the pressure will continue to drop, and eventually all the pressure developed by the water tank will be expended in overcoming friction and in pushing water up into the building against the force of gravity.

Subsequently, if more water is drawn by the fixtures on the lower floors of the building, the pressure used to overcome the increased friction will be balanced by a lowering of pressure on the upper floors, resulting in a decreased flow rate from the

can be increased without decreasing the amount of water drawn from the pipes only by increasing the pipe diameter or providing booster pumps. Larger pipes can carry the same volume of water at lower velocities and, hence, with lower frictional pressure losses.

Pressure losses are also caused by the formation of mineral deposits that decrease the effective diameter of the pipes and increase frictional pressure losses. For this reason, all pipes installed in a building should be large enough to allow for the restrictions caused by normal formation of mineral deposits during the life of the building.

Because it is extremely unlikely that all the fixtures in a building will be used at the same time, the pipe diameter selected by the plumbing designer is based on the frictional pressure losses caused by the maximum probable flow rate, not upon the maximum potential flow rate. Fig. 2 shows the relationship between the probable maximum demand for water and total potential

Pressures and Flow Rates for Common Plumbing Fixtures

Fixture	Recommended Pressure at Fixture (p.s.i.)	Ordinary Maximum Flow Rate (g.p.m.)
Lavatory basin	8	3.0
Bath tub	5	6.0
Shower	12	5.0
Water closet (with flush tank)	15	3.0
Water closet (with flush valve)	10 to 20	15 to 40

flow capacities of the installed fixtures. To calculate the maximum probable flow rate for a new building, the plumbing designer refers to statistical tables which list the observed water demands of fixtures installed in buildings housing equivalent activities.

Recommended operating pressures and customary maximum flow rates for some common plumbing fixtures are shown in the accompanying table.

Booster pumps are sometimes installed in outlying areas of municipal water systems to offset the frictional head losses in long supply lines. Likewise, booster pumps are used in tall buildings when supply pipes of adequate size would be either too expensive or too bulky. The additional pressure supplied by the booster pump offsets the increased frictional losses of the smaller pipe and ensures that enough pressure will be available to maintain the flow of water to the upper floors during peak periods of consumption.

Sewerage System.—The sewerage system of a building consists of two parts: the drainage system and the venting system. The drainage portion comprises pipes leading from the various fixture drains to the central main, which is connected to the municipal or private sewerage system.

The venting system consists of pipes leading from an air inlet (usually located on the roof of the building) to various points within the drainage system; it protects the sanitary traps from siphoning or blowing by equalizing the pressure inside and outside the drainage system. Fig. 3 shows a typical arrangement of plumbing fixtures and drain and vent piping, with the drainage sections shaded.

Sanitary fixture traps provide a water seal between the sewer pipes and the rooms in which plumbing fixtures are installed. The most commonly used sanitary trap is a U bend, or dip, installed in the drainpipe adjacent to the outlet of each fixture. A portion of the waste water discharged by the fixture is retained in the U, forming a seal which separates the fixture from the open drainpipes. Fig. 4 shows how water standing in the trap seals the pipe.

Sometimes the protection offered by sanitary traps is inadequate, and a device known as an indirect waste must be installed on the fixture to prevent sewage from backing up in a clogged drainpipe. Indirect wastes are designed so that liquids discharged from the fixture fall through an air gap into a receiver; this is connected through an ordinary sanitary trap to the sewer. If the section of pipe connected to the fixture drain ends at a level above that which wastes can reach in the receiver, the air gap between the fixture drain and the receiver top will prevent wastes from backing up into the fixture.

FIG. 2.—GRAPH SHOWING WATER DEMAND AS A FUNCTION OF TOTAL FIXTURE CAPACITY

Curve A is for buildings in which majority of toilets are flush-valve type. Curve B should be used if majority of toilets have flush tanks

higher fixtures. In some instances, water may even stop flowing on the upper floors of a building.

Because friction losses increase approximately as the square of the velocity of the water flowing in the pipes, water pressure

Plumbing regulations usually specify that indirect wastes be installed on restaurant coffee urns, automatic washing machines, dishwashers and other apparatus where great caution must be exercised to prevent contamination.

In addition to sanitary traps and indirect wastes, fixture outlets are sometimes equipped with interceptors to separate and retain materials that should not be discharged into the sewerage system. For example, grease interceptors are often installed in restaurants to remove insoluble oils, fats and greases that, in large quantities, may impair the digestive action required for proper sewage treatment. (See also REFUSE DISPOSAL; SEWAGE DISPOSAL.)

Venting System.—If the drainage system is not vented, or if it is improperly vented, the air in the pipes will be evacuated by the flow of waste materials. For example, when the water discharged from a lavatory basin flows through the drainpipe, it pushes some of the air out of the pipe. If the waste water flows past openings where branch pipes join the system, air may be drawn from these branches by the suction created by the running water. If there were no sanitary traps at the fixture outlets, air drawn from the drainpipes by the flow of waste water would be replaced by air drawn into the pipes through the open drains on the fixtures.

However, the water retained in the sanitary traps blocks such a flow of air into the sewerage system just as it blocks the flow of sewer gases out of the system. Therefore, a partial vacuum may be formed inside an unvented drain, siphoning water from the sanitary trap and breaking the seal between the fixture and the sewer. Conversely, the water in the trap may be blown out through the fixture drain if the pressure within the drainage system should suddenly rise above atmospheric pressure. This could occur in an improperly vented system if air were trapped and forced into side branches by the flow of large quantities of water through the pipes.

In a small dwelling, where all the bathroom and kitchen fixtures can be located adjacent to a large vertical drainpipe, a separate venting system is usually not needed if the top of the vertical drain is open to the atmosphere. However, when this type of venting is used, the drainpipes must be large enough to handle peak waste loads without filling with water; otherwise, air will not be able to reach all parts of the system, and some of the traps may siphon or blow. If some fixtures are far enough from the central drainpipe so that they cannot be vented properly through the drainage system itself, separate air vents must be provided for them.

Water closets are usually provided with individual vents because the volume of water which they discharge makes it difficult to vent them properly through the drainpipes without using excessively large pipes.

FIG. 3.—BUILDING DRAINAGE AND VENTING SYSTEM (DRAINAGE PIPING SHADED)

FIG. 4.—SANITARY FIXTURE TRAP SHOWING THE WATER COLUMN WHICH SEALS THE FIXTURE FROM SEWER GASES, BACTERIA AND VERMIN THAT ARE COMMONLY FOUND IN DRAINAGE SYSTEMS

Sanitation.—The central problem in the construction and repair of plumbing systems is the maintenance of sanitary conditions. Because both potable water and waste water are in close proximity in plumbing fixtures, such as water closets, lavatories and bathtubs, there is always danger of a cross connection which will allow contaminated water to enter the potable water pipes. Most cross connections are the result of faulty plumbing design and installation; they occur in leaking plumbing fixtures or through back siphonage in water-supply pipes. An example of a cross connection caused by leaking plumbing fixtures is an overhead sewerage pipe which drips sewage into an open laundry tub or sink. This could be eliminated by repairing the leak, but a better way would be to install the drainage pipes so that they never cross above open plumbing fixtures.

Another example of bad design which can lead to hazardous cross connections is a building in which both potable and non-potable water are distributed in interlocked systems separated only by valves. If one of the interlocking valves fails or is inadvertently opened, the nonpotable water can contaminate the potable water.

Although the pressure in a water-supply system normally remains above atmospheric pressure, abnormal conditions may lower it sufficiently to induce back siphoning. The easiest way to safeguard fixtures against back siphoning is to install the water inlet well above the level of the waste water in the fixture. Most sinks and bathtubs are designed so that the inlet pipe is above the top of the overflow outlet. In these fixtures waste water cannot possibly submerge the inlet pipe and form a cross connection.

However, in some fixtures the space between the inlet pipe and the highest level of the waste water is so small that waste water could be sucked across the air gap and into the supply pipe under certain conditions.

Fixtures which have submerged inlets or improperly sized air gaps should never be installed unless they are safeguarded with vacuum breakers. Whenever the water pressure drops below atmospheric pressure, the vacuum breaker opens and allows air to flow into the water pipes, thus destroying the partial vacuum inside the pipes and eliminating the danger of back siphoning. Because vacuum breakers are mechanical devices subject to wear and corrosion, they should be checked from time to time to make sure that they are operating properly. In the case of the water closet, proper flushing action cannot be achieved unless the water inlet is submerged in the waste-water bowl, and thus plumbing codes specify that both flush-valve and flush-tank water closets should be equipped with vacuum breakers.

PLUM RAINS are the persistent precipitation of the "Bai-u" season, the period when plums are ripening, in Japan and immediately adjacent areas. In Japan proper, particularly from Kyushu to northeastern Honshu, these rains, which are also important to the rice economy, extend from approximately early June to about the middle of July.

The rains tend to be of the moderate, prolonged type, rather than the cloudburst type. The sky is overcast for many hours, and the weather is depressing. The phenomenon is much better developed on the east side of Japan than on the west. Tokyo, for example, has an average in June of 1 clear day, 9 partly cloudy and 20 cloudy days; bright sunshine is observed during only about a third of the daylight hours. Tokyo records measurable rainfall on an average of 16 days in June, and the average monthly total is about 6½ in. The accompanying average maximum temperature is about 68° F (20° C); the average minimum is about 62° F (about 17° C).

The beginning of the plum rains is earliest in low latitudes and later northward. In Formosa and the Ryukyus, precipitation begins to increase in the middle of May and continues heavy

until early July. In northern Korea, the season begins in late June and lasts through July.

The rains are associated with eastward-moving cyclones, accelerated near Japan by the Pacific high-pressure area. Occasional failure of the rains to appear has resulted in damaging droughts. (W. A. Bm.)

PLUNKET, OLIVER (1629–1681), Roman Catholic primate of all Ireland and martyr, who was the last man to suffer martyrdom for the Catholic faith in England, was born at Loughcrew, Meath. He was in Rome from 1645 until 1669, being educated and ordained there and serving then as professor of theology at the College of Propaganda Fide and as the representative of the Irish bishops at the Holy See. Appointed archbishop of Armagh and primate of all Ireland in 1669, he arrived in the following year at a time when, after prolonged repression, the Catholic Church was greatly disorganized, with only one aged bishop at liberty. Setting himself to restore order and discipline in accordance with the precepts of the Council of Trent, Plunket kept on good terms with the English and the Protestants until in 1673, under renewed persecution, he was obliged to go into hiding. For the next five years he laboured under conditions of increasing difficulty, brought to a climax by the Titus Oates (*q.v.*) plot of 1678. In the following year he was betrayed, arrested, and imprisoned in Dublin Castle. His trial at Dundalk was made absurd by the ignominious witnesses for the prosecution; he was taken to London, where, after protracted and farcical legal proceedings, he was sentenced to be hanged, disemboweled, and quartered; the sentence was carried out at Tyburn on July 1, 1681, before a large crowd. Plunket was beatified by Benedict XV in 1920. His head is preserved at Drogheda and his body at Downside Abbey, near Bath. (M. Dk.)

PLUNKET, WILLIAM CONYNHAM PLUNKET, 1ST BARON (1764–1854), Irish lawyer, orator, and statesman, lord chancellor of Ireland from 1830 to 1841, was born at Enniskillen in County Fermanagh on July 1, 1764, the fourth son of Thomas Plunket, a Presbyterian minister. Educated at Trinity College, Dublin, he entered Lincoln's Inn in 1784, and was called to the Irish bar in 1787. He achieved a wide practice in the courts of equity, was made a king's counsel in 1797, and in the following year was elected to the Irish Parliament as member for Charlemont, County Armagh. He was an ardent upholder of the Irish Parliament's new independence (*see IRELAND: History*), but he abhorred the democratic doctrines of the French Revolution. He admired British constitutional traditions, and held that increased political rights should be given to Roman Catholics and Protestant Dissenters.

Entering the Irish Parliament after the abortive Irish insurrection of 1798, Plunket found that the English prime minister William Pitt was actively completing his plans to achieve a legislative union between England and Ireland which would abolish the Irish Parliament. Henry Grattan, the chief defender of Irish legislative independence, had withdrawn from public life in 1797, and the defense of the Irish Parliament fell largely to Plunket. His vehement speeches made him the chief spokesman of the opposition to Pitt's designs and when Grattan returned to Parliament in January 1800, he deliberately took his seat beside Plunket as its most uncompromising champion. In one of the most famous speeches of those historic debates, Plunket declared that he would oppose the union "to the last gasp of my existence and with the last drop of my blood; and when I feel the hour of my dissolution approaching I will, like the father of Hannibal, take my children to the altar and swear them to eternal hostility against the invaders of their country's freedom."

However, with the passing of the Act of Union in August 1800, his passions cooled and he devoted himself to his legal practice and soon became a leader of the equity bar in Dublin. In 1803 he appeared for the crown in prosecuting Robert Emmet for his futile rising in Dublin. He accepted office under Pitt as Irish solicitor general (1803–05) and attorney general (1805–07). He was elected to the English Parliament as member for Trinity College, Dublin, in 1812 and was soon regarded as one of the finest orators in the House of Commons, where he became a leading

advocate of the cause of Catholic emancipation. He had no sympathy for popular agitation, and though he pleaded for increased Catholic rights, he opposed Daniel O'Connell's Catholic association. He pressed steadfastly for a Catholic relief bill which would yet allow to the British government a veto on the appointment of Catholic bishops. After the Emancipation Act (1829), Plunket passed from political to judicial eminence; he was appointed chief justice of the common pleas in Ireland in 1827 and was raised to the peerage as Baron Plunket of Newton. In 1830 he was made lord chancellor of Ireland, an office he held until his retirement in June 1841. He died on Jan. 4, 1854, at his house, Old Connaught, near Bray, County Wicklow, and was buried in Dublin.

See D. R. Plunket, The Life, Letters and Speeches of Lord Plunket, 2 vol. (1867). (D. G.)

PLUNKETT, SIR HORACE (CURZON) (1854–1932), pioneer of Irish agricultural cooperation who strongly influenced the development of the cooperative movement in Great Britain and the Commonwealth, was born at Sherborne House, Sherborne, Gloucestershire, on Oct. 24, 1854, the third son of the 16th Baron Dunsany. Educated at Eton and at University College, Oxford, Plunkett spent the years 1879–89 cattle ranching in Wyoming, U.S., for his health's sake. From his return to Ireland in 1889, he devoted himself to the cooperative movement, founding the Irish Agricultural Organization Society in 1894. Unionist member of Parliament for South County Dublin from 1892 to 1900, he became vice-president of the new Department of Agriculture and Technical Instruction for Ireland in 1899. His subsequent experience convinced him of the need for the independence of a united Ireland within the commonwealth. Plunkett's friendship with Theodore Roosevelt and his continued visits to the United States had considerable influence on country life policy there. In 1919, in London, he endowed a trust, now the Plunkett Foundation for Co-operative Studies, as a commonwealth agricultural research and information centre. He had been made a fellow of the Royal Society in 1902 and knight commander of the Royal Victorian Order in 1903. His writings include *Ireland in the New Century* (1904) and *The Rural Life Problem of the United States* (1910). Plunkett died at Weybridge, Surrey, on March 26, 1932. (M. Dr.)

PLURALISM AND MONISM are theories giving respectively the answers "many" and "one" to two quite distinct questions: first, *how many things are there in the world?*; and second, *how many kinds of things are there in the world?* Much confusion is engendered if this distinction is not clearly maintained. Pluralism and monism as theories of substance, answers to the first question, have no necessary connection with pluralism and monism as theories of *kinds* of substance, answers to the second question. Philosophers can be cited to exemplify the four possible combinations of views: Descartes is a pluralist and Hegel a monist in both senses, Spinoza is a monist of substance and a pluralist of kinds, Bertrand Russell a pluralist of substance and a monist of kinds. Such definitions as "monism attempts to explain the entire universe from a single principle" misleadingly suggest, by compounding the two questions, that Spinoza and Russell are guilty of some inconsistency from which the writings of Descartes and Hegel are free.

A theory of substance seeks to establish the nature of what it is that can properly be said to exist independently or in its own right, or, again, what are the ultimate subjects of discourse: "Substance is that which requires nothing but itself in order to exist" (Descartes). The existence of some subjects of discourse—complexes such as armies, men's characters, material objects—will be dependent on that of others—simples such as soldiers, actions, sense-experiences—in that what we know or believe about the complex will be an inference from, or a convenient paraphrase of, what we know or believe about the simple. An ultimate subject of discourse, then, a simple or substance proper, something that exists in its own right, is something whose existence we can discover directly and without having first to discover or assume the existence of something else. The natural answer to the question "how many simple things, existing and discoverable independently, are there in the world?" is "many." Monism of substance—the theory that the world as a whole is the only true thing, held by Par-

menides, Spinoza and Hegel—being at odds with our common beliefs, requires substantiation by argument. The point requiring proof is that nothing but the world as a whole is really independent of anything else. This—the doctrine of internal relations—will be stated and examined below.

A theory of kinds, "ultimate" kinds, of substance seeks to establish how many irreducibly different kinds of knowledge or experience we must admit. Two things are of different kinds, in a very wide sense, if there is any feature that one has and the other lacks. And since, unless there were such a feature, they would not be distinct and thus not be two things at all (the identity of indiscernibles), everything is of a different kind from everything else. But we do not in practice use such a generous criterion of difference in kind. Only some features of things are relevant to answering the question "what kind of thing is that?"; e.g., its being a chair or a tree or a house or a star. Other features are relevant to answering questions about what kind of chair, tree, house or star it may be. Others again are not relevant to answering any questions about kinds at all; e.g., being two feet from the wall, being the property of King Faruk. The set of features determining "natural kinds," possible answers to the question "what kind of thing is that?" is wider than the set determining "ultimate kinds." Roughly, the latter set consists of various forms of occupancy of space—location, volume, solidity. Whatever occupies space can be discovered only and always by sensation. Whatever does not occupy space can be discovered only and always by self-consciousness and introspection ("reflection"). The natural answer to the question "how many ultimate kinds of thing, objects of distinct types of knowledge or experience, are there in the world?" is "many." Monism of kinds—the theory that there is only one fundamental type of knowledge or experience, held by Democritus, Berkeley and Russell—being nearly as much at odds with common beliefs as monism of substance, also requires substantiation by argument. The point requiring proof is that there is only one source of knowledge, only one type of experience.

Whether or not parts of the world are independent of one another and whether or not there is more than one source of knowledge are questions whose internal connection, if any, does not at once leap to the eye. Hence the importance of distinguishing the varieties of pluralism and monism to which the attempt to answer them gives rise.

THEORIES OF SUBSTANCE

The Eleatics.—Xenophanes is credited with the remark "All is One," but his main importance is rather as a critic of polytheism than as a philosopher. It is with Parmenides that the first significant statement appears of the view that only the world as a whole ("being") exists in its own right. The world confronts us as a theatre of change; but this becoming, of which the senses inform us, is unreal, an illusory appearance, no proper object of knowledge. Only "being," discovered by reason, is real and truly exists. Being does not change, it never came into existence, it will never pass away, it is timeless. For what could change it, how could it arise from or pass into not-being? It is also, incidentally, spatial, finite and spherical in shape. Since empty space is a contradictory notion, "being" is everywhere. This tinge of materialism, important for its influence on Democritus and the atomists, is hardly consistent with the view that only reason informs us about reality, and it was not taken over by Plato.

Zeno, Parmenides' disciple, reinforced his master's theory with famous arguments against plurality and motion. Of these the most influential and relevant to the present purpose concerns the size of a world of many things, which, Zeno argues, must be both infinitely large and infinitely small and is thus an impossibility: infinitely small, since its ultimate components must be indivisible and thus without size, and no collection, however large, of things without size has any size; infinitely large, since the world, being divisible, has size, and the parts into whichever has size is divided, however far the division is carried, must themselves have size, so that it must consist of an infinite number of parts with size. This is a harder nut to crack than Parmenides' arguments against pluralism and was considered by Hume, Kant and Russell.

Spinoza.—In Part I of Spinoza's *Ethics* the classical argument for monism of substance—the proof that only the world as a whole (*Deus sive Natura*—God or Nature) exists independently—is to be found. It depends ultimately on Spinoza's theory of explanation. To understand anything, to have knowledge of it, is to know its cause or explanation. Now the causes of most of the things with which we are familiar are external to them, the changes of state of other things. To have knowledge of something whose cause is external to it requires us, therefore, to look beyond the thing itself to whatever it is that is needed to explain it. A thing of this kind, then being essentially dependent on something other than itself, does not come up to Spinoza's somewhat exigent requirement for being a substance; viz., "that, the conception of which can be formed independently of another thing." Now either this quest for causes must continue indefinitely or terminate in a thing which somehow explains itself, a *causa sui*, which will be a true substance. All its characteristics being essential or definitive parts of its inner nature, we will be able to deduce all the truths requisite to total "understanding" of it from the conception of the thing by itself.

Spinoza argues that if there is a plurality of things each must be limited by and thus dependent on the others. There can only be one truly independent, self-subsistent, self-explanatory thing, and it must be unlimited, infinite. It follows that the view that God transcends the world that He created is mistaken, a conclusion supported by such unhappy consequences of the creation theory as the problem of evil and the consequent imperfection, in respect of power or goodness, of God. God is therefore immanent in, indeed identical with, created Nature, they are not two things but the same thing viewed in different ways: as creating (*Natura naturans*) and as created (*Natura naturata*). Only the whole, then, is intelligible in itself, for the rather negative reason, it would seem, that it at any rate must be self-explanatory since the existence of anything external to it which could explain it is logically excluded.

Hegel.—It is one of the aims of Hegel to overcome the deficiency last mentioned. He attempts to produce a conception of the world as a whole, the absolute, which will provide a positive ground for thinking it to be self-explanatory and thus to exclude the possibility (compatible with Spinoza's view) that the world as a whole is a brute fact, neither self-explanatory nor to be explained by anything else. This attempt involves the distinction of cause from reason. The cause of something is merely externally connected with it, a mere concomitant happening. The reason for a thing, however, has an internal, logical connection with it, in this case there is real connection not just coincidence. But only thoughts stand in logical relationships to one another. So the absolute is a logically articulated system of thoughts. Hegel, like Spinoza, bases his version of monism on the unintelligibility on its own account of what is finite or limited (for the finite is necessarily limited by something else and so to that extent dependent on it). But his requirement that truly intelligible explanation must be rational or logical, a matter of the logical interrelation of thoughts, is a further development.

Internal Relations.—The monisms of Spinoza and Hegel are both variants of the doctrine of internal relations. Their fundamental thesis may be expressed in two ways: (1) nothing but the world as a whole is independent of everything else; and (2) everything in the world is in its real nature essentially related to everything else. For, it is argued, we do not fully understand anything until we know all of its relations to other things. As against the normal view that things, identified by the set of their defining or essential properties, stand in various external, contingent relations which are not part of their definition or essence, it is held that the true definition of a thing contains all its qualities and relations, everything that can truly be affirmed of it. This sets an ideal of understanding that cannot be attained, since it requires that to understand anything properly one must know everything about it, in effect everything whatever. To "understand" a thing, to know what it is, is enough to be able to recognize or identify it: by picking out a set of qualities as a thing we obtain a reference point whose relations to other such reference points empirical in-

quiry must establish. Not only is the theory of internal relations no account of our actual conception of things, it is not an account of any conception of things in which inquiry into the nature of the world remains possible, but rather a dream of the termination of science, of a way of thinking fit for an omniscient being.

THEORIES OF KINDS

The question "how many ultimate kinds of thing are there?" is, it has been seen, an inquiry into the number of sources of knowledge or forms of experience. In practice the philosophical debate on this issue has predominantly concerned itself with the nature of our experience of and knowledge about minds. Do we get to know about thoughts, decisions and feelings (our own and those of others) in the same way as we get to know about material, extended, spatially located things? *Prima facie*, we seem to have independent access to two quite distinct orders of things: by sensation to an outer world of material things and other persons, by introspection to an inner world of our own mental states. Monism of kinds denies this apparent independence and distinctness. Sensation and introspection are assimilated into experience *simpliciter*, the impassable frontier between inner and outer is dismantled. That there is some distinction, at least *prima facie*, between the mental and the material is not denied by any but the most ardent materialist. What is objected to is the view that this distinction, this "bifurcation of nature" as A. N. Whitehead calls it, is ultimate, that we are the inhabitants of two distinct worlds, at best contingently connected. For the theory of bifurcation has given rise to two historically obtrusive problems, that of the relation between mind and body and that of our knowledge of other minds (the latter problem, on a wide view, may be seen as a more modern version of the former).

Dualism.—The classical exponent of dualism is Descartes. On his view the created world is composed of two quite distinct kinds of substance, minds and bodies, to be distinguished by their "essential attributes" which are, respectively, thought and extension. In practice Descartes takes these essential attributes as constituting the whole essence of mind and body, so that he comes to hold that the mind is always active and thinking and that matter is extension and empty space an impossibility. Locke complements this account of things with an appropriate account of our knowledge of things when he declares that all knowledge is based on sensation and reflection. For Descartes the distinction of the two kinds of thing depends on his theory of self-knowledge. Our own existence, he holds, is self-evident, since, whatever we may doubt, we cannot doubt that we doubt and, therefore, exist. On the other hand our knowledge of the external world is mediate, indirect. Our natural propensity to infer external causes for our sensations is only to be indulged and trusted if we are assured of the existence of God. The essential feature of dualism, then, is its intuitive theory of self-knowledge which contrasts our immediate and infallible knowledge of our own minds with our more devious and fallible acquaintance with everything else.

The first difficulty to arise from this is the familiar mind-body problem. In human perception and action we are confronted with what seem to be clear cases of the interaction of these two quite distinct orders of things, mental and material. Now there are two grounds on which philosophers have refused to acknowledge this apparent interaction: first, the conservation principles of physics seem to exclude the irruption of mental causes into the physical order; second, it was held that effects must resemble their causes. This did not prevent Descartes from inconsistently accepting the interaction of mind and body, with the pineal gland as a medium of divine agency. But since, by the conservation principle, every physical event is already physically accounted for and, by the metaphysical principle, that cause must resemble effect, mental causes of physical events are impossible as well as superfluous, mental events can at best be occasions and not causes of physical ones. This result leads in Descartes' immediate successors to the view that there are two quite independent but divinely adjusted series of events within which, but not between which, causal relations obtain; on the one hand is the system of inner experiences, the felt, private order of states of mind; on

the other is extended nature, a true causal system of material substances with merely geometrical, "primary" qualities. The triumphs of physics tend to degrade the mental world to a shadow play, an epiphenomenon, the view of materialism. The remote and unintelligible character of material substance conceived in purely geometrical terms leads to idealism.

Materialism.—This doctrine regards mental life as a more or less illusory exhalation of physiological processes, on its relation to which experienced mental life depends for such reality as it can be held to possess. Only that which can be mechanically explained is real. Mental life, as experienced, is a by-product, a mere symptom of mechanical transformations at the physiological level. The determination, which this theory evidences, to replace the obvious by the speculative in the interests of tidiness is still to be found among scientists and depends on laying down as universally to be followed in all spheres of inquiry a method notably successful in certain specialized investigations. Even the advances of contemporary neurophysiology do little to transform the speculative metaphysics of physiological materialism into a well-confirmed scientific theory.

Idealism.—Where materialism arises from the triumph of the material conception of cause, idealism is based on the paradox of the material conception of substance. Berkeley attacked the notion of material substance propounded by Descartes and Locke as unintelligible, a nonentity. It could not cause, or, a fortiori, resemble, the ideas of sensation on which all knowledge is based since *ex hypothesi* it could not be independently observed and compared with them. Material things are not distinct substances of a purely geometrical character on this view, for such things are unknowable, but are, rather, orderly and regular systems of sense experiences. Idealists of a Hegelian type argued that reality to be knowable must be mental in character, a system of ideas, which derives its objectivity for the observer not so much from being the beneficent contrivance of God as from being the logically necessary unfolding of the thoughts of an absolute mind (which is not perhaps very different).

Neutral Monism.—Idealists, while rejecting material substance, still distinguish mental substance, mind, from the ideas that it has. In Berkeley this leads to an uncomfortable and arbitrary proposal of a theory of notions to explain knowledge of mental substance, a theory required because we do not have any ideas of mind. But the "mental" character of ideas is based on their essential dependence on these somewhat feebly supported substances. Neutral monism reverses the relation by construing the ideas of sense as fundamental, the immediate objects of knowledge, and things, mental and material, as constructions out of these basic neutral elements. This view, developed by William James from some ideas of J. F. Herbert, became the foundation of Russell's theory of knowledge.

Other Minds.—The second major problem to which dualism gives rise is that of our knowledge of other minds. For, if dualism is correct, while we know about ourselves directly and infallibly we only find out about the mental life of others on the evidence of their behaviour and can never directly verify what we infer from this. Other minds are as unknowable in themselves, apart from their supposed effects, as the material substance attacked by Berkeley. Attempts have been made to identify our knowledge of self and others, to bridge the abyss exposed by criticism of the argument from analogy, by asserting that we have direct, "intuitive" knowledge of the mental states of others or that we have to find out about our own mental states by a more or less prolonged, tentative and piecemeal procedure. "Telepathic" idealism comes to grief on the inescapable logical distinctness of your experience of your anger from my, telepathic, experience of your anger. Its diametrical opposite, G. Ryle's "dispositional" materialism, provides a valuable criticism of the Cartesian intuitive theory of self-knowledge in all departments of mental life. But the attempt to construe having pains, sensations and images as tendencies to behave in certain ways comes up against a mass of very ordinary conviction to the contrary.

See also references under "Pluralism and Monism" in the Index.
(A. M. Q.)

PLURALITY OF CAUSES is the matter of the philosophical question whether one and the same kind of effect can be produced in different cases by different causes. This is distinct from the question whether the cause of an effect is as a rule a complex of several factors or conditions. Even if each cause is allowed to be complex, there still remains the question whether any one of several such complex causes can produce the same kind of effect as another. In other words, can one cause ever act vicariously for another? J. S. Mill in his *System of Logic* gave an affirmative answer, which examples taken from practical experience seem to support. For instance, many different causes can produce death. But many effects that are sufficiently similar for practical purposes are really very different when closely scrutinized. While two bodies may be equally dead, examination will show different effects in the one that died, say, of poisoning and in the one that died naturally. In short, the total effect produced by one kind of cause can always be distinguished, in theory at least, from that produced by any other, but, where the interest is centred in broad kinds of effect and where differences of detail do not matter much, the doctrine of the plurality of causes holds good. See also CAUSALITY.

PLUTARCH (c. 46–after 119), Greek biographer and miscellaneous writer, who from the 16th century to the early 19th was among the most popular of classical authors. His writings were admired for their wisdom as well as for their information, and they were long used as source books for anecdotes and moral *exempla*; they influenced the origins and development of the essay, the biography, and the writing of history; and from his *Lives* were derived the generally accepted images of the great historical figures of Greece and Rome.

Plutarch was born at Chaeronea in Boeotia, the son of Aristobulus, himself a biographer and Academic philosopher. At the time of Nero's visit to Greece in 66/67 Plutarch was studying mathematics and philosophy at Athens under Ammonius. Later, public duties brought him several times to Rome, where he lectured on philosophy, made many friends and perhaps enjoyed the acquaintance of Trajan and Hadrian; the Suda lexicon's statement that Trajan bestowed consular rank upon him may be true, but Eusebius' story that Hadrian made him governor of Greece is probably apocryphal. A Delphic inscription reveals that he possessed Roman citizenship; his *nomen* Mestrius was no doubt adopted from his friend, the consular L. Mestrius Florus.

Plutarch traveled widely, visiting central Greece, Sparta, Corinth, Patrae (Patras), Sardes, and Alexandria, but he made his normal residence at Chaeronea, where he held the chief magistracy and other municipal posts, and directed a school with a wide curriculum, in which philosophy, especially ethics, occupied the central place. He maintained close links with the Academy at Athens (he possessed Athenian citizenship), and with Delphi, where from c. 95 he held a priesthood for life; he may have won Trajan's interest and support for the renewed vogue of the oracle. The size of Plutarch's family is uncertain. In the *Consolatio* to his wife Timoxena on the death of their infant daughter he mentions four sons; of these at least two survived childhood, and he may have had other children.

Plutarch's literary output was immense. The 227 titles listed in the so-called catalogue of Lamprias which is usually printed with his works are not all authentic, but equally they do not include all he wrote. The order of composition cannot be determined.

Lives.—Plutarch's popularity rests primarily on his *Bioi Paralleloi* (*Parallel Lives*) of Greek and Roman soldiers, legislators, orators, and statesmen. These, dedicated to Trajan's friend Sosius Senecio, who is mentioned in the *Demosthenes*, *Theseus*, and *Dion*, were designed to encourage mutual respect between Greeks and Romans. By exhibiting noble deeds and characters they were also to provide patterns of behaviour to copy.

The first pair, *Epaminondas* and *Scipio*, and perhaps an introduction and formal dedication, are lost. But the plan was clearly to publish in successive books biographies of Greek and Roman heroes in pairs, chosen as far as possible for their similarity of character or career, and each followed by a formal comparison. Internal evidence suggests that the *Lives* were composed in Plu-

tarch's latest years, but the order of composition can be only partially determined; the present order is a later rearrangement based largely on the chronology of the Greek subjects, who are placed first in each pair. In all, 22 pairs survive (one pair being the double group of *Agis and Cleomenes* and the *Gracchi*) and four single biographies, of Artaxerxes, Aratus, Galba, and Otho. The *Aratus* is addressed to one Polycrates, a descendant of the Achaean general.

The *Lives* display impressive learning and research. Many sources are quoted, and, though Plutarch probably had not consulted all these at first hand, his investigations were clearly extensive, and compilation must have occupied many years. For the Roman *Lives* he was handicapped by an imperfect knowledge of Latin, which he had learned late in life; for, as he explains in *Demosthenes*, political tasks and the teaching of philosophy fully engaged him during his stay in Rome and Italy. The form of the *Lives* represents a new achievement, not closely linked with either previous biography or Hellenistic history. The general scheme is to give the birth, youth and character, achievements, and circumstances of death, interspersed with frequent ethical reflections; but the details vary with both the subject and the available sources, which include anecdote mongers and writers of memoirs as well as historians. Plutarch never claims to be writing history, which he distinguishes clearly from biography. He seeks to delight and edify the reader, and does not conceal his own sympathies, which are especially evident in his warm admiration for the words and deeds of Spartan kings and generals; his virulent and unfair attack on Herodotus probably sprang from his feeling that the Ionian had done Athens more and Boeotia less than justice.

Moralia.—Plutarch's surviving writings on ethical, religious, physical, political, and literary topics are collectively known as *Ethica* (*Moralia*), and amount to more than 60 essays. They are mainly cast in the form of dialogues or diatribes. The former vary from a collection of set speeches to informal conversation pieces set among members of Plutarch's family circle; the date and dramatic occasion are rarely indicated. The diatribes, which often show the influence of Menippean satire, are simple and vigorous. The literary value of both is enhanced by the frequent quotation of Greek poems, especially verses of Euripides and other dramatists.

The two educational works "How a young man ought to hear poetry" (which qualifies the old Platonic objection to poetry) and "How to listen," together with the pseudo-Plutarchean treatise "On the education of children," were popular and influential during the Renaissance. In the treatise on moral virtue Plutarch discusses how virtue must subordinate unreason to reason within the soul, a theme developed in many other of the works dealing with popular ethical problems; these adduce examples from the lives of famous men, and contain sound but unoriginal moralizing. Among them are "Vice and Virtue," "How to recognize progress in virtue" (dedicated, like the *Lives*, to Sosius Senecio), "How to distinguish a flatterer from a friend," "On having many friends," and "On Fortune." Another group of a rhetorical and epideictic character includes the historical essays "On the fortune of Alexander," "On the fortune of the Romans," and "Whether the Athenians were more famous in war or in wisdom"; these resemble the traditional topics of declamation, and parallel to them are "Whether water or fire is more useful," "Whether virtue can be taught," and "Whether mental or bodily afflictions are the worse."

Plutarch's interest in animals and their minds emerges in two books "On eating flesh," in "Whether land or sea animals are more intelligent" (a question which receives no clear answer), and *Gryllus* or "Do animals reason?" an entertaining dialogue set on Circe's island in which a pig, one of Odysseus' transformed companions, attacks the Stoic argument denying reason to animals, and convinces Odysseus of the moral superiority of many animals over man. The tenets of the philosophical schools are the subject of several essays, for instance "Platonic questions," "On the creation of the soul in the Timaeus" (expounding Plutarch's views about Plato's teaching on the soul), "Against Colotes" (attacking Epicurean views), and "On the impossibility of living pleasurably according to Epicurus' teaching"; several other essays criticize

Stoic doctrines. Physical and medical problems are discussed in "Precepts on health," "On the face of the moon's disk," and "On primary cold" (which argues that cold is something real, not the mere absence of warmth).

The treatises dealing with political issues are of especial interest. "Political precepts" is an enlightening account of political life in contemporary Greece; in "Whether a man should engage in politics when old" he urges his friend Euphanes to continue in public life at Athens; Stoic ideas appear in the short work "To the unlearned ruler" and the fragmentary argument that "The philosopher should converse especially with princes"; in "The one, the many, and the few in government" the author (who may not be Plutarch) favours monarchy. The virtues of family life are treated in "On brotherly love," "On the love of one's offspring," and "Conjugal precepts"; with the *Consolatio* to his wife goes the fine essay "On exile"; the *Amatorius* is a discussion of love, which favours normal heterosexual relationships.

Plutarch's interest in religious history and antiquarian problems can be seen especially in a group of striking essays, the early "Daemon of Socrates," and three later works concerning Delphi, "On the failure of the oracles," in which the decline of the oracle is linked with the decline in the population, "On the E at Delphi," interpreting the word EI at the temple entrance, and "On the Pythian responses," seeking to reestablish belief in the oracle. Contemporary with these is "On Isis and Osiris," with its mystical tones; the dialogue "On the late vengeance of God," staged in Delphi, argues that the postponement of divine vengeance is to give time for repentance. "Convivial questions" (nine books) and "Greek and Roman questions" assemble a vast collection of antiquarian lore; "On the malignity of Herodotus" displays the local patriotism of a Boeotian; and the "Comparison of Aristophanes and Menander" prefers Menander for moral reasons.

Among the more important works no longer accepted as authentic are the *Consolatio* to Apollonius for his son, the "Lives of the Ten Orators," "On Fate," the "Short sayings of kings and commanders," the "Short sayings of Spartans" and "Proverbs of the Alexandrines."

Assessment.—Plutarch's perennial charm and popularity arise in part from his treatment of specific human problems without raising disquieting solutions. He writes easily and superficially with a wealth of anecdote. His style is predominantly Attic, though influenced by the contemporary Greek which he spoke; he follows rhetorical theory in avoiding hiatus between words, and he is careful in his use of prose rhythms. He is clear, but rather more diffuse than the strict Attic canon would allow. Plutarch's philosophy was eclectic, with borrowings from the Stoics, Pythagoreans and Peripatetics (but not the Epicureans) grouped around a core of Platonism. His main interest was in ethics, but he developed a mystical side, especially in his later years; he remarks that he had been initiated into the mysteries of Dionysus, and both as a Platonist and as an initiate he believed in the immortality of the soul. He believed too in the superiority of Greek culture and in the meritoriousness and providential character of the Roman empire. Personally he preferred a quiet and humane civic life as a citizen of a small Boeotian town, where his writing and teaching did much to illuminate the darkness of provincial life in 1st-century Greece.

Reputation and Influence.—Plutarch's later influence has been profound. In his own time and in later antiquity he was loved and respected; his *Lives* inspired the rhetorician Aristides and the historian Arrian to similar comparisons, and a copy accompanied the emperor Marcus Aurelius when he took the field against the Marcomanni. Gradually Plutarch's reputation faded in the Latin West, but he continued to influence philosophers and scholars in the Greek East, where his works became a school book. Proclus, Porphyry, and the emperor Julian all quote him, and the Greek Church Fathers, Clement of Alexandria and Basil the Great, imitate him without acknowledgment. His works were familiar to all cultivated Byzantines, who set no barrier between the pagan past and the Christian present. It was mainly the *Moralia* which appealed to them; but in the 9th century Photius read the *Lives* with his friends. At the end of the 13th century Planudes set out

to transcribe Plutarch's works in an edition which has left its mark on the manuscript tradition.

Plutarch's works were introduced to Italy by Byzantine scholars with the revival of classical learning in the 15th century, and Italian humanists had already translated them into Latin and Italian before 1509, when the Aldine *Moralia*, the first of his works to be printed in the original Greek, appeared at Venice. The first original Greek text of the *Lives* was printed by P. Junta at Florence in 1517, and by the Aldine Press in 1519. The *Lives* were translated into French in 1559 by Jacques Amyot (*q.v.*), who also translated the *Moralia* (1572). The first complete edition of the Greek texts by H. Stephanus (Estienne; *q.v.*), in 1572, marked a great improvement in the text.

That Rabelais knew Plutarch well is proved by the frequency with which he quotes from both the *Lives* and the *Moralia*. It was Montaigne, however, who read Plutarch in Amyot's version, who first made his influence widely felt. The style of the *Essais* (1580–88) owed much to the *Moralia*, and from the *Lives* Montaigne adopted Plutarch's method of revealing character by illustrative anecdote and comment, which he applied to self-revelation. Moreover, the *Essais* made known the ideal, derived from Plutarch's presentation of character and openly expressed opinion, of "high antique virtue and the heroically moral man" which became the humanist ideal of the Renaissance period.

The *Lives* were translated into English, from Amyot's version, by Sir Thomas North (*q.v.*) in 1579. His vigorous idiomatic style made his *Lives of Noble Grecians and Romans* an English classic, and it remained the standard translation for more than a century. Even when superseded by more accurate translations, it continued to be read as an example of Elizabethan prose style. North's Plutarch was Shakespeare's source for his Roman plays, and influenced the development of his conception of the tragic hero. The literary quality of North's version may be judged from the fact that Shakespeare lifted whole passages from it with only minor changes.

The complete *Moralia* was first translated into English from the Greek by Philemon Holland (*q.v.*) in 1603. Its influence can be seen in the 1612 edition of Bacon's *Essays*, which contain counsels of public morality and private virtue recognizably derived from Plutarch. Bacon was more attracted by Plutarch the moralist than by Plutarch the teller of stories or painter of character, but to the Renaissance mind it was the blend of these elements that gave him his particular appeal. His liking for historical gossip, for the anecdote and the moral tale, his portrayal of characters as patterns of virtue or vice (in the manner of the morality play and the "character"), his emphasis on the turn of fortune's wheel in causing the downfall of the great, all suited the mood of the age, and from him was derived the Renaissance conception of the heroic and of the "rational" moral philosophy of the ancients.

Historians and biographers in the 16th and 17th centuries followed Plutarch in treating character on ethical principles. Izaak Walton knew Plutarch well, and his *Lives* (collected 1670, 1675) imitated him in dwelling on the strength, rather than the weakness, of his subjects' characters.

Plutarch continued to be read throughout the 17th and 18th centuries. John Dryden edited a new translation of the *Lives* first published in 1683–86, and abridged editions of it appeared in 1710, 1713 and 1718. Another translation, by John and William Langhorne, published in 1770, was frequently reprinted. The *Moralia* was retranslated in 1683–90 and also frequently reprinted. In France, Amyot's translations were still being reprinted in the early 19th century, and their influence on the development of French classical tragedy equaled that of North's version on Shakespeare. Admiration for those heroes of Plutarch who overthrew tyrants, and respect for his moral values, inspired the leaders of the French Revolution; Charlotte Corday, who assassinated Jean Paul Marat, spent the day before that event in reading Plutarch.

In Germany, the first collected edition of Plutarch's works was published in 1774–82. The *Moralia* was edited by D. Wyttenbach in 1796–1834, and was first translated in 1783–1800. The *Lives*, first edited in 1873–75, had already been translated in 1799–1806. The German classical poets—Goethe, Schiller, and Jean Paul

(Johann Paul Richter) especially—were influenced by his works, and he was read also by Beethoven and Nietzsche. During the 18th century the veneration in which Plutarch was held as a moralist led to the rumour that he had written a life of Jesus, which was said to have been discovered.

In the 19th century, Plutarch's direct influence began to decline, partly as a result of the reaction against the French Revolution, partly because the rise of the Romantic Movement introduced new values and emphasized the free play of passions rather than their control, partly because the more critical attitude of scholars to historical accuracy drew attention to the bias of his presentation of fact. He was still admired, however, notably by the U.S. poet, philosopher and essayist Ralph Waldo Emerson, and although in the 20th century his direct influence was small, the popular ideas of Greek and Roman history continued to be those derived from his pages.

PLUTARCH OF ATHENS (4th–5th century A.D.), Greek philosopher, preceded Syrianus as head of the Platonic School at Athens and was one of the teachers of Proclus. He died at an old age in A.D. 431/432. The commentaries that he wrote on a number of Platonic dialogues and on Aristotle's *De Anima* have not survived and are known only from allusions in later writers. The commentary on the *De Anima* had a particularly high reputation, ranking with that of Alexander of Aphrodisias. So little is known of Plutarch's teaching that it is impossible to form any estimate of its importance or originality. What later writers say does not suggest that it was notably different from that of other Athenian Neoplatonists, though perhaps he was more interested in and influenced by Aristotle's philosophy than some of them. (All Neoplatonists of course studied Aristotle and were to some extent influenced by him; he was in particular their principal authority in logic and natural philosophy.) Plutarch seems to have been particularly interested in Aristotle's psychology: it is said that he not only wrote a commentary on Aristotle's chief psychological work but that in his own teaching on the soul he combined the Platonic doctrine of recollection with the Aristotelian theory of the intellect. (A. H. Ac.)

PLUTO (PLUTON): see **HADES**.

PLUTO is the outermost known major planet, ninth in order of distance from the sun. Its mean distance from the sun is 39.5 times that of the earth, but its orbit is so eccentric ($e = 0.25$) that at perihelion, as will occur in 1989, it will come closer to the sun than Neptune does. The inclination (17°) and the orientation of its orbit (node to perihelion = 114°) are such that the orbits of Neptune and Pluto do not now intersect. Pluto's period of revolution is 248 years. Pluto is so faint, 15th magnitude, that a 20-in. telescope is necessary to see it. Its diameter has been measured as 3,700 mi., halfway between that of Mars and Mercury. This measurement is difficult because of Pluto's faintness and small angular diameter ($0''.23$). With a diameter of approximately 3,600 mi., Pluto's volume is 0.1 that of the earth and its mass would probably be about 0.1 that of the earth also, since it is not likely that its density exceeds that of the earth. Pluto's reflecting power derived from its apparent brightness and measured diameter is about what might be expected (albedo = 0.17). Its mass as derived from its attraction on Neptune is about that of the

earth, but this value is also uncertain. If Pluto is as large as the earth, as indicated by its calculated mass, its reflectivity must be extremely low. It therefore seems probable that Pluto's diameter is about 0.45 and its mass one-tenth that of the earth.

The brightness of Pluto varies about 10% in a period of 6.39 days, indicating that its surface is not uniformly bright and that the planet rotates on its axis in a period of 6.39 days.

Pluto was discovered in a systematic search for a trans-Neptunian planet predicted by Percival Lowell on the basis of its attraction on Uranus (*Memoirs of the Lowell Observatory*, vol. i, 1915). William Henry Pickering, using discrepancies in the motion of Neptune, also predicted a trans-Neptunian planet in about the same place as that derived by Lowell (*Harvard Annals*, vol. lxxxii, no. 3, 1919). Pluto was discovered on Feb. 18, 1930, by Clyde William Tombaugh at the Lowell Observatory on photographs he had taken on Jan. 23 and 29, 1930 (*Scientific Monthly*, vol. xxxiv, Jan. 1932). He recognized the new planet by its motion, which was much slower than that of the numerous asteroids also recorded on the photographs. In spite of the fact that Pluto was near the position predicted by the computations, its small mass indicates that its discovery was due to the thoroughness of the search rather than to the theoretical calculations. Both Lowell and Pickering predicted that the unknown planet would be much larger and brighter than Pluto is. (S. B. N.)

PLUTONIUM, a chemical element, centrally important in nuclear engineering and in the history of atomic weapons, has the symbol Pu and atomic number 94. Since all of its isotopes are produced synthetically, the atomic weight depends on the particular isotopic composition of any given sample, which in turn depends on the source of the sample. Plutonium occupies a position in the periodic system of the elements as the fifth member of a transition series, the actinide series, which includes the heavy elements with atomic numbers 90 to 103—elements in which an inner electronic shell (the 5f shell) is being filled (see **PERIODIC LAW**; **TRANSURANIUM ELEMENTS**).

Discovery.—Plutonium was discovered at the University of California at Berkeley by Glenn T. Seaborg, Edwin M. McMillan, Joseph W. Kennedy and Arthur C. Wahl. In late 1940 and early 1941, bombarding uranium with deuterons, they produced the isotope with mass number 238 of the 94-proton element, which they named plutonium, after the planet Pluto. The fissionable isotope of major importance, Pu^{239} , was discovered immediately thereafter in 1941 by Kennedy, Emilio Segrè, Wahl and Seaborg, working in the same laboratory. Only a very small specimen of plutonium was produced for the first experiments conducted with a weighable amount—0.0005 mg. (about $\frac{1}{80,000,000}$ oz.). However, this minute sample was sufficient to reveal that plutonium-239 was susceptible to fission by bombardment with slow neutrons, and therefore that its production in substantial quantities was a matter of extreme importance to national defense. The team of scientists, who sent communications concerning the discovery to the editor of the *Physical Review* in January, March and May 1941, decided to withhold these reports from publication. *The Trans-uranium Elements* (Yale University Press, 1958) by Seaborg points out that "the announcement to the world of the existence of plutonium was in the form of the nuclear bomb dropped over Nagasaki." The first pure chemical compound of plutonium, in the form of Pu^{239} , free from carrier material and all other foreign matter, was isolated by Burris B. Cunningham and Louis B. Werner at the wartime Metallurgical Laboratory of the University of Chicago (now the Argonne National Laboratory) in August 1942. This provided the first sight of a synthetic element and was the first isolation of a weighable amount of an artificially produced isotope of any element.

Occurrence.—Plutonium occurs in nature in very small concentrations in uranium-bearing ores. Such plutonium was first detected, in Canadian pitchblende, by Seaborg and Morris L. Perlman in 1942. The isotope involved is Pu^{239} , which is formed continuously as a result of the absorption of neutrons by U^{238} . The neutrons are those emitted during the spontaneous fission of uranium and those resulting from the action of alpha particles on the nearby light elements. The concentration of Pu^{239} is deter-

TABLE I.—Concentrations of Plutonium in Common Ores

Ore	Pu ²³⁹ /ore*
Pitchblendes:	
Canada (13.5% U)	9.1×10^{-12}
Belgian Congo (38% U)	4.8×10^{-12}
Colorado (56% U)	3.8×10^{-12}
Monazites:	
Brazil (0.24% U)	2.1×10^{-14}
North Carolina (1.64% U)	5.9×10^{-14}

*Fraction by weight of Pu²³⁹ in ore.

mined by the equilibrium balance between its rate of formation and its rate of radioactive decay.

Production.—By far the most important source of plutonium is one or another type of nuclear reactor, or chain-reacting pile, in which it is manufactured. An example is a nuclear reactor consisting of natural uranium, or uranium slightly enriched in the fissionable isotope U²³⁵, and some neutron-slowing material, or moderator, such as carbon (graphite) or heavy water (deuterium oxide). In such a reactor a self-sustaining nuclear chain reaction results from the fission of the uranium isotope U²³⁵ with neutrons. A large proportion of the excess neutrons are absorbed by non-fissionable U²³⁸ to form U²³⁹, which decays by two successive beta-particle emissions to fissionable Pu²³⁹. In such production methods some of the Pu²³⁹ captures neutrons to form heavier isotopes (Pu²⁴⁰, Pu²⁴¹, etc.); hence the isotopic composition of any given sample of plutonium depends on its source (see ATOMIC ENERGY: Nuclear Reactors; NEUTRON: Nuclear Energy). The plutonium is separated by chemical means from the highly radioactive fission products and the uranium and other foreign material. The chemical plants for this purpose are massive structures designed to solve the grave problems inherent in handling extremely high levels of radioactivity due to the fission products, and the operations are carried out entirely by remote control through heavy walls of shielding material. (See NUCLEAR ENGINEERING.)

The earliest industrial process for the isolation of plutonium, used at the Hanford Engineer Works in the state of Washington during World War II, was based on bismuth phosphate and lanthanum fluoride as carrier precipitation agents. This process was conceived by Stanley G. Thompson, Seaborg and their collaborators at the Metallurgical Laboratory of the University of Chicago. Neutron-irradiated uranium was dissolved in nitric acid and, after the addition of sulfuric acid, plutonium in oxidation state IV was coprecipitated with bismuth phosphate. The precipitate was dissolved in nitric acid, the plutonium IV was oxidized to plutonium VI, and a by-product precipitate of bismuth phosphate was formed and removed, the plutonium VI remaining in solution. After the reduction of plutonium VI to plutonium IV, the latter was again coprecipitated with bismuth phosphate and the whole decontamination cycle was repeated. At this point the carrier was changed to lanthanum fluoride, and a similar oxidation-reduction cycle was carried out using this carrier, which achieved further decontamination and concentration. The plutonium at this point was sufficiently concentrated so that final purification could be carried out without the use of carrier compounds.

Many of the present-day commercial processes for the separation and decontamination of plutonium are based upon extraction into organic solvents. Solvent extraction is performed in packed columns or pulsed columns, or in a series of mixing-settling chambers in which the aqueous phase and solvent phase pass in counter-current flow in a multistage process. Throughout the world these processes are very similar in principle, and can be illustrated by one of the U.S. processes, the industrial "Purex" process, which uses tributyl phosphate diluted with a kerosene-type solvent. The uranium slugs are dissolved in nitric acid, plutonium is fixed as plutonium IV, and the acid strength is adjusted so that plutonium IV and uranium VI are extracted away from the fission products. In a second part of the process, the solvent is contacted with a nitric acid solution containing a reducing agent. Uranium VI is left in the tributyl phosphate phase while plutonium III is removed. Both the uranium and the plutonium undergo additional processing before complete purification is achieved.

Uses.—The main use of plutonium—specifically isotope Pu²³⁹—

is in the production of nuclear (atomic) energy. Nuclear reactors may be built to use Pu²³⁹ as fuel, and these reactors can also be operated in conjunction with the abundant isotope of uranium, U²³⁸. The reactors can generate energy by "burning" the Pu²³⁹, while at the same time they produce more Pu²³⁹ as a result of the absorption of neutrons in U²³⁸. Such a system is known as a "breeder." In theory, this process should make it possible eventually to convert all the nonfissionable U²³⁸ into fissionable Pu²³⁹. Hence the rate of nuclear power production could be increased steadily. A fissionable isotope such as Pu²³⁹ gives rise to an amount of heat energy equivalent to about 10,000,000 kw-hr. per pound when it undergoes the fission reaction completely. For industrial purposes the energy may be used in this heat form, but in most cases it is converted into the more convenient electrical form by means of more or less standard turbine equipment. The efficiency with which heat energy can be turned into electrical power in an industrial nuclear reactor depends on the details of the particular machine, but it seems likely that efficiencies of the order of 30–50% may in time be realized.

Pu²³⁹ can be used as an explosive ingredient for nuclear (atomic) weapons. Nuclear explosives also have important peaceful applications: in large-scale excavation, in undertakings where high temperatures and pressures are needed (e.g., in mining and in the recovery of oil and gas from low-grade sources) and in research.

Although most of the chemical and metallurgical investigations of plutonium have been conducted with Pu²³⁹ (half-life 24.4×10^3 years), the future will see increasing use of the longer-lived Pu²⁴² (half-life 3.79×10^5 years) and eventually the much longer-lived Pu²⁴⁴ (half-life 7.6×10^7 years). These isotopes can be produced by intensive slow neutron irradiation of Pu²³⁹; at best, the Pu²⁴⁴ yield is very small and requires extremely high neutron flux and extremely long irradiation time. Radioactive tracers—by-products formed by neutron absorption in various chemical elements inserted into a chain-reacting unit—are used in basic science, agriculture, industry and medicine.

The isotope Pu²³⁹ can be used as a source of electricity through conversion of its heat of radioactive decay by means of thermoelectric or thermionic devices. Such power units are long-lived, since the half-life of Pu²³⁹ is 86.4 years; and, because they are very compact and light in weight, they are admirably suited for use in space and in certain terrestrial circumstances. Huge amounts of Pu²³⁹, perhaps amounting to ton quantities, are being prepared for this purpose, through the neutron irradiation of Np²³⁷

(see NEPTUNIUM) by the reaction $\text{Np}^{237} (n, \gamma) \text{Np}^{238} \xrightarrow{\beta^-} \text{Pu}^{238}$

Metallic Plutonium.—Plutonium metal has unusual properties. It exists in six allotropic forms below its melting point (639° C) at atmospheric pressure—behaviour unique to this metal. The temperatures at which the phase changes occur have been determined by a dilatometric method and by thermal analysis.

The density of α -plutonium (monoclinic) is quite high, 19.737 g. per cubic centimetre; however, the densities of the other phases are lower: 17.65 for β -plutonium (body-centred monoclinic), 17.19 for γ -plutonium (face-centred orthorhombic), 15.92 for δ -plutonium (face-centred cubic), 15.99 for δ' -plutonium (face-centred tetragonal) and 16.48 for ϵ -plutonium (body-centred cubic).

Marked changes in electrical resistivity and thermal expansion accompany the phase changes. The electrical resistivity of α -plutonium is higher than that of any other metallic element at room temperature, being 145 μ ohm-cm. Plutonium metal is highly electropositive.

The metal also forms intermetallic compounds with aluminum, beryllium, cobalt, iron, manganese, nickel and silver. These com-

Hydrides.—The plutonium hydrides PuH_2 (fluorite structure) and PuH_3 (hexagonal structure) are prepared by the action of hydrogen on plutonium metal at temperatures between 150° and

200° C. The entire composition range $\text{PuH}_2\text{--PuH}_3$ has been studied. The hydrides are of special importance because thermal decomposition produces finely divided metal which is a useful starting point for the preparation of many other compounds.

Oxides.—The plutonium oxygen system does not present the degree of complexity exhibited by the uranium oxygen system (see URANIUM), largely because of the stability of the dioxide. Analogous behaviour is shown in the variable composition of the so-called sesquioxide ($\text{PuO}_{1.5-1.75}$), a typical mixed oxidation state oxide, similar to those formed by uranium, praseodymium, terbium, titanium, and many other metals. Its composition shows continuous variation with changes in temperature and pressure of oxygen above the oxide. The limits of composition given above are only approximate. Near the lower limit of the oxygen range the structure is hexagonal. A higher proportion of oxygen causes the oxide to assume the cubic C type of modification of the rare-earth sesquioxides. Plutonium sesquioxide may be formed by the thermal decomposition of the dioxide at about 1,500° C in high vacuum.

Plutonium dioxide is the most important oxide of the element. Almost all compounds of plutonium are converted to the dioxide upon ignition in air at about 1,000° C. The ignited oxide is chemically inert at ordinary temperatures and has a well-defined composition; for these reasons it is a satisfactory compound for weighing in the gravimetric determination of plutonium.

The dioxide is frequently used as the starting material in the synthesis of other compounds of plutonium. In these cases prolonged high-temperature ignition of the oxide is avoided, since this leads to progressive chemical inertness.

Plutonium dioxide was the first compound of the element to be isolated and weighed in pure form; in fact, it was the first compound of any synthetic element to be separated in pure form in weighable amounts. It was also the first compound of a synthetic element to be identified by X-ray diffraction methods.

Halides and Oxyhalides.—All of the halides except the tri-iodide, the hexafluoride and the oxyfluoride may be prepared by the hydrohalogenation of the dioxide or of the oxalate of plutonium III at a temperature of about 700° C. With hydrogen fluoride the reaction product is PuF_4 , unless hydrogen is added to the gas stream, in which case the trifluoride is produced. With hydrogen iodide the reaction product is PuOI , and the other oxyhalides may be formed by the addition of appropriate quantities of water vapour to the hydrogen halide gas. Plutonium tri-iodide is produced by the reaction of the metal with hydrogen iodide at about 400° C.

TABLE IV.—Important Halides and Oxyhalides of Plutonium

Compound	Colour	Crystal Structure	Density (g./cc.)	M.P. (°C)	B.P. (°C)
PuF_3	violet	hexagonal, tysonite type	9.32	1,425	2,190*
PuF_4	light brown	monoclinic	7.0	1,037	—
PuF_5	deep brown gas, red or reddish-brown solid	orthorhombic	—	50.75	—
PuCl_3	emerald green	hexagonal, UCl_3 type	5.70	760	1,770*
PuBr_3	green	orthorhombic	6.69	681	1,510*
PuI_3	bright green	orthorhombic, PuBr_3 type	6.9	777	1,380*
PuOF	metallic	tetragonal	9.76	above 1,635	—
PuOCl	blue green	tetragonal, PbFCl type	8.81	—	—
PuOBr	deep green	tetragonal, PbFCl type	9.07	—	—
PuOI	green	tetragonal, PbFCl type	8.46	—	—

*Estimated value.

Although PuF_5 has not been prepared, compounds such as CsPuF_6 and RbPuF_7 have.

Plutonium hexafluoride, the volatile plutonium analogue of uranium hexafluoride, can be prepared by the reaction of pure gaseous fluorine with plutonium tetrafluoride at 700° C. It is unstable with respect to dissociation into fluorine and plutonium tetrafluoride and is a powerful fluorinating agent. The rate of decomposition when stored as a vapour is, however, only about 0.1% per day. When it is stored principally as a solid, the radiation decomposition induced by the intense alpha-particle activity destroys about 1.5% of the hexafluoride per day.

Plutonium oxyfluoride has been prepared by heating PuF_3 to

1,635° C in an atmosphere of argon and oxygen.

The trihalides are appreciably volatile at moderately elevated temperatures and all except the trifluoride may be purified by sublimation in quartz tubes in high vacuum at around 800° to 1,000° C.

Except for the trifluoride, the halides are so hygroscopic that they must be handled in an anhydrous atmosphere. The trifluoride shows so little tendency to hydration that the anhydrous salt is obtained directly upon precipitation from aqueous solution.

The crystal chemistry of the halides and oxyhalides of plutonium is closely similar to that of the analogous compounds of the rare earths—a consequence of the fact that these compounds are predominantly ionic and that the cations have nearly the same ionic radii. Sharp absorption bands and, under certain conditions, fluorescence similar to that in the analogous rare-earth compounds also are observed.

Carbides, Nitrides, Silicides and Sulfides.—Plutonium forms several binary compounds which are of interest because of their refractory character and stability at high temperatures. These compounds include carbides and at least one nitride, one silicide and one sulfide of the element. The monocarbide is formed by the reaction of the dioxide in intimate mixture with carbon at about 1,600° C; higher carbides such as Pu_2C_3 and PuC_2 can also be synthesized. The mononitride may be obtained by heating the trichloride in a stream of anhydrous ammonia at 900° C; it is prepared more easily, however, by the reaction of finely divided metal with ammonia at 650° C. Although the lower temperatures are favourable to the production of higher nitrides, none is readily obtained, in contrast with the uranium-nitrogen system in which compositions up to $\text{UN}_{1.75}$ are easily realized.

The disilicide is formed when a slight stoichiometric excess of calcium disilicide is heated with plutonium dioxide in vacuum at about 1,550° C. The disilicide is only moderately stable in air and burns slowly to the dioxide when heated to about 700° C.

Plutonium "sesquisulfide" may be prepared by prolonged treatment of the dioxide in a graphite crucible with anhydrous hydrogen sulfide at 1,340°–1,400° C, or by reaction of the trichloride with hydrogen sulfide at 900° C. A monosulfide is also known to exist.

Only the most important compounds of plutonium have been mentioned in this article; very many compounds are known.

PLUTUS, in Greek mythology, the god of abundance or wealth, a personification of *ploutos*, the Greek for "riches." According to Hesiod, he was born in Crete, the son of Demeter (*q.v.*) and Iasion. His birth was represented at the Eleusinian mysteries. A blind god, he receives his sight in the *Plutus*, the last of Aristophanes' comedies, with fantastic results. In art he appears chiefly as a child with a cornucopia. He was sometimes confused with Pluto.

PLYMOUTH, a city, county and parliamentary borough, naval base, and seaport of Devon, Eng., 42 mi. (68 km.) SW of Exeter by road. Pop. (1961) 204,409; (1963 est.) 209,900. It lies between the rivers Plym and Tamar which flow into Plymouth Sound, the city's southern boundary. The Sound, with an area of 4,500 ac. (1,821 ha.), is sheltered by a mile-long breakwater. In the Sound lies Drake's (formerly St. Nicholas) Island. The southern waterfront is called the Hoe. To the north lies Dartmoor. The Cattewater (the estuary of the Plym) covers 290 ac. (117 ha.), with 8,000 ft. (2,438 m.) of quayage; at its mouth is Sutton Harbour with 4,500 ft. (1,372 m.) of quayage. The Hamaoze (the estuary of the Tamar) is an extensive anchorage used principally by the Royal Navy. West of the Hoe lie Millbay Docks with

an outer basin of 35 ac. (14 ha.) and an inner basin of 13 ac. (5 ha.). The Cattewater, Sutton Pool (the ancient tidal harbour), and Millbay Docks accommodate merchant ships and yachts. Plymouth Hoe is dominated eastward by the Citadel, built by Charles II to replace the Tudor castle defending the approaches to the Cattewater and Sutton Harbour. Plymouth was created a county borough in 1888, became a city in 1928, and was granted the dignity of a lord mayor in 1935.

Plymouth suffered severe damage from air raids in World War II. More than 1,100 citizens were killed, and among thousands of buildings destroyed or damaged were every major civic building and half the city's schools and churches, including the 15th-century mother church of St. Andrew. A plan for reconstruction was approved during the war, and the first new road in the central area, Royal Parade, was opened by King George VI in 1947. The near completion of the central reconstruction was celebrated when Queen Elizabeth II opened the 14-story civic centre in 1962. The new Plymouth has some of the most modern commercial, shopping, and civic centres in Great Britain. The central area is built around a 1,000-yd. north-south axis (Armada Way) between the new central station and the Hoe. Shopping and business streets extend at right angles to this axis. New approach roads from the east and west link Plymouth with new bridges over the Plym and Tamar. Reconstruction included the building of several satellite communities where light industries were introduced. Among the more important buildings restored are the Church of St. Andrew, the 19th-century guildhall, and the central public library. The city is the headquarters of the Marine Biological Association. It has several museums and an art gallery; an extensive new College of Technology; the Royal Naval Engineering College; two television stations; and several parks, one of which, Central Park, contains a zoo and a sports centre. The oldest district, the Barbican, features a number of 16th- and 17th-century buildings.

Plymouth Airport lies 4 mi. NNE of the city centre; main line railways communicate with all parts of Britain, and the main road between the Midlands and Cornwall passes through the city. Plymouth is an important yachting centre.

The principal industry is that in the naval dockyard of Devonport; others include the manufacture of machine tools, shoes, clothing, precision instruments, office equipment, lubrication equipment, radio and television sets, fertilizers, chemicals, and engineering products. These goods constitute the principal exports; the main imports are timber, fruit, vegetables, grain, and coal.

Plymouth was named Sudtone in Domesday Book, and its original harbour is still called Sutton Harbour. A developing trade and the shipment of armies to France in the 14th century led to rapid growth. In 1439 Plymouth became the first English town to be incorporated by act of Parliament. In the 16th century the attempts of Sir Walter Raleigh (Raleigh) to colonize Virginia were made from Plymouth; it was the home port of Drake, Grenville, and the Hawkins family, and from there the British fleet sailed to attack the Spanish Armada. Storm damage caused the "Mayflower" to call at the Devonian port, and so well were the Pilgrim Fathers received that they wrote afterward how they had been "courteously used by divers friends there dwelling." In 1620 they sailed from Barbican quay (recorded by a stone slab, an arch, and an inscription) to found Plymouth, Mass. In the Civil War Plymouth was intermittently besieged by Royalist forces. In 1690 the royal dockyard was begun on the eastern bank of the Tamar, and the town of Plymouth Dock (in 1824 renamed Devonport) was founded adjacent to it. The third town of Stonehouse developed between Devonport and Plymouth, all amalgamating as Plymouth in 1914. The painters Sir Joshua Reynolds, James Northcote, and Benjamin Haydon were all natives of the area, and the explorer Robert Falcon Scott was born at Devonport. Plymouth has two parliamentary divisions, Devonport and Sutton. The American-born Nancy Viscountess Astor, elected for Sutton in 1919, became the first woman to sit in the House of Commons. (W. B. H.)

PLYMOUTH, the seat of Plymouth County, Mass., U.S., and site of the first permanent settlement by Europeans in New England, is 37 mi. SE of Boston on Plymouth Bay. Thousands of visitors are drawn annually by the historic interest of the town

and its attractions as a summer resort. The modern town has a large cordage works, supplied by its own ships. Other important industries are cranberry growing and processing, commercial fishing, and varied manufactures such as sheeting for photoengraving and curtains. Seafaring was the heart of the older business life of the community and active wharves and boatyards remain.

Plymouth was founded by Pilgrims (*see* PILGRIM FATHERS)—Separatists from the Church of England who, in their search for religious toleration, had emigrated first to the Netherlands and then to North America. Sailing in the "Mayflower" (*q.v.*), the settlers reached the coast of New England in November 1620, and an exploring party arrived in the Plymouth area on December 21, now celebrated as Forefathers' Day. The "Mayflower" anchored in the harbour five days later. (For a more detailed account of the colony's beginnings, and for its subsequent history, *see* MASSACHUSETTS: *History*.) The storied Plymouth Rock, first identified in 1741, became a symbol of freedom in 1774 when it was split by dragging it to Liberty Pole Square in prerevolutionary agitation. It rests today on its original waterfront site under a protecting portico of granite. Rising behind the rock is Cole's Hill, where during their first terrible winter the Pilgrims buried half their number, leveling the ground, and sowing it to grain in the spring "lest the Indians know how many were the graves." The first fort and watchtower were on Burial Hill, which contains the graves of William Bradford (*q.v.*) and others of the original Pilgrims, although the oldest stone is dated 1681. "Plimoth Plantation," a nonprofit educational foundation, in 1957 began reconstructing an accurate replica of First Street in 1627 and other buildings of the early village. "Mayflower II," a good-will ship sent as a gift from England in 1957, is on display. Several mid-17th-century houses still stand in the town. Pilgrim Hall, built in 1824, contains relics of the Pilgrims and early colonial times. Many surviving original records of the colony are in the Registry Building. The National Monument to the Forefathers was dedicated in 1889. For comparative population figures *see* table in MASSACHUSETTS: *Population*. *See* also references under "Plymouth, Mass.," in the Index. (C. M. C.)

PLYMOUTH BRETHREN, a community of Christians who received the name from Plymouth, Eng., where their first congregation in England was established in 1831, under the leadership of Benjamin Wills Newton, Samuel Prideaux Tregelles, and others. The movement had originated in Dublin some six years earlier, as a spontaneous endeavour by a few young men (chiefly Edward Cronin and Anthony Norris Groves) to enjoy Christian fellowship in disregard of denominational frontiers and thus to recapture the simplicity of the apostolic church. They were early caught up in the keen contemporary interest in biblical prophecy, particularly after they were joined by John Nelson Darby (1800–82). This former clergyman in the Church of Ireland quickly became the dominant personality in the movement, and he founded groups of like-minded people in many parts of the British Isles and on the continent of Europe, especially in French Switzerland, where he spent the greater part of 1838–45.

His return to England in 1845 was followed by a cleavage among the Brethren. The principal occasion was a conflict which developed between Darby and Newton, on grounds partly of doctrine and partly of ecclesiastical polity. Darby's followers formed a closely knit federation of churches and were known as Exclusive Brethren; the others, called Open Brethren, maintained a congregational polity and less rigorous standards of communion. The leading Open Brethren church was Bethesda Chapel, Bristol, where George Müller (famous for his philanthropic work for orphans) was joint pastor. Exclusive Brethren, by carrying through consistently their basic tenets on church fellowship (summed up in Darby's words, "separation from evil is God's principle of unity"), have suffered further worldwide divisions. The first of these took place in 1881, when Darby's ablest disciple, William Kelly, separated with his followers from the main Exclusive body. Today, while some Exclusive parties refuse practically all collaboration with Christians outside their own circle, others take an active part in interdenominational work of an evangelical character, as do the Open Brethren.

Brethren of all parties recognize no order of clergy or ministers as distinct from the laity, although a number of them who are suitably qualified give all their time to evangelistic or pastoral ministry. Their most distinctive meeting is the communion service, where members of the local church, together with Christian friends who care to join them, sit round the Lord's Table with no presiding minister, and their devotions (prayer, hymn singing, Bible reading, and exposition) proceed in no prearranged order. Practically all Open Brethren and some of the Exclusive parties practise believers' baptism; many Exclusives, however, following Darby, baptize the children of members ("household baptism").

All parties maintain the faith of the ecumenical creeds, except that one Exclusive group denies that Christ was the Son of God before his incarnation, while acknowledging his eternal preexistence in the Godhead. For the rest, their doctrines are generally evangelical (more Calvinist than Arminian) and their approach to the Bible conservative. They have inherited from their founders a live eschatological awareness, which frequently finds expression in their hymnology; but no single line of eschatological interpretation is imposed.

Brethren are found throughout the English-speaking world and in most European countries. In the United States, which they reached in the early 1860s, there are eight groups, distinguished for statistical purposes by roman numerals I through VIII, with an inclusive membership of around 33,000. The largest groups are I and II (the latter with about 15,000 members), which are in practice one group.

The Plymouth Brethren have been active in foreign missionary work ever since Groves led a missionary expedition to Baghdad in the early 1830s. Groves later established missionary work in India. Their missionaries are located principally in Central Africa, India and Latin America; they observe the comity of missions. The editors of the periodicals *Echoes of Service* (Bath, Eng.) and *The Fields* (New York) act as channels of communication for the Open Brethren's foreign mission field, commonly called "Christian Missions in Many Lands."

J. N. Darby's *Collected Works* were edited by W. Kelly, 32 vol., with supplementary vol. (1867-83). (F. F. B.)

PLYNLIMON (Pumlumon meaning five "risings" or "swellings"), a hilly superstructure or monadnock on the surface of the high plateau of central Wales, partly in Cardiganshire and partly in Montgomeryshire, is about 14 mi. inland from Aberystwyth and 10 mi. W of Llanidloes. The highest point, known as Pen Pumlumon Fawr, attains 2,468 ft. (752 m.). The monadnock consists of Lower Paleozoic rocks of a gritty nature which in turn are smeared with a coating of stiff boulder clay. This type of country was most likely forested in early times, certainly up to the 1,000-ft. (305 m.) contour, but it is now grass covered with wide stretches of bracken. These areas provide only a poor pasture for sheep and summer grazing for young beef cattle. Much of the surface is boggy. Heavy rainfall and deep winter snows feed the many streams which radiate from the upland—the Severn, Wye, and Clywedog flowing to the Bristol Channel in a southeastward direction, and the Rheidol and Llynant westward to Cardigan Bay. Mining for lead, zinc, and copper, and quarrying are no longer carried on. Anthropologists have noted the survival of a number of very early (Paleolithic) physical characteristics among the present-day inhabitants of this upland area. (E. G. Bow.)

PLYWOOD, a composite wood panel made of three or more layers glued together with the grain of adjoining plies at right angles to each other. For thin panels veneer is used exclusively, but for thicker panels sawed lumber often is used as the centre ply, or core, in which case it is known as lumber-core plywood.

The veneer may be rotary cut (*i.e.*, peeled from the log), sliced or, less commonly, sawed in thin sheets from a flitch or bolt. Rotary-cut veneer always presents a flat-grain or tangential surface, whereas sliced and sawed veneers may be cut in a radial or any other plane through the log. Veneer used for plywood usually varies in thickness from $\frac{1}{32}$ to $\frac{1}{8}$ in., but both thinner and thicker veneers often are used. Thin veneers have an advantage, espe-

cially for the outer or face plies, in that they set up less severe transverse stresses with changes in moisture content, thereby reducing warping and surface checking of panels. The use of thin veneer also makes valuable wood go further. In lumber-core panels the plies next to the faces, or the crossbands, usually are thicker than the face plies and largely control the stability of the panel. Plywood is almost always composed of an odd number of plies so that the grain of corresponding plies from the outside in runs in the same direction, thereby balancing and stabilizing the construction.

Plywood has a number of advantages over solid wood: it can be manufactured into large sheets with limited defects; it is stronger across the grain of the face plies than are boards of the same thickness; because the plies cross each other, shrinking and swelling are almost eliminated; splitting in handling and nailing is greatly reduced; and wood of the lower grades can be used for the interior plies. Since veneer can be dried in a few minutes, dry plywood can be produced from green logs in a day.

Two types of plywood are made: interior plywood, for use only in dry locations, and exterior plywood, for which water-resistant glues are used.

Since successively cut layers of thin veneers are similar in appearance, identical areas from adjacent sheets can be matched so as to make highly ornamental symmetrical patterns.

PLZEN (German PILSEN), the fifth largest city of Czechoslovakia, and the administrative and industrial centre of the West Bohemian *kraj* (region), lies about 68 mi. (110 km.) SW of Prague by rail. Pop. (1961) 141,583. Geographically it has a remarkable site, for the great fan of five tributary streams which forms the Berounka River gathers in the Plzen Basin, of which the city is the focal point. The convergence of valleys is emphasized now by the railway network, and the meeting there of seven main roads. There is a coalfield to the northwest but the once profitable seams have been worked out. The brown forest soils of the countryside, long cleared of woodland, are relatively fertile and on the whole well farmed in spite of the recurrent problem of summer drought. The farming specialties are sugar beets and hops, although the famous breweries depend largely on the hop farms round Zatec. The concentration of urban growth in one sizable city, unlike the clusters of secondary towns in the Ohre (Eger) Basin, and the markedly Czech nature of the greater part of the population,

distinguish Plzen from much of Bohemia.

Plzen was recorded as a settlement in the 10th century and is said to have received its charter as a town in 1292. Its medieval and Renaissance prosperity is evident from the fine church of St. Bartholomew and the 16th-century town hall. The church has the highest tower in Bohemia (325 ft. [99 m.]). Plzen was one of the strongholds of Roman Catholicism during the Hussite Wars in the 15th century (see HUSSITES).

Plzen's industrial importance developed mainly in the mid-19th century, notably with the establishment of the Mestansky pivovar (citizens' brewery) in 1842 and of the Skoda (now V. I. Lenin) armament works in 1859. The reputation of the "Pilsener" beer became international, and the Skoda factories, although better known for arms production, manufactured rolling stock, machinery for breweries and sugar refineries, and later parts for the motor industry. The factories, severely damaged in World War II, were quickly rebuilt and remain the basic group of Czechoslovak heavy industry. The nearby Sumava (Bohemian) Forest favoured the timber and paper industries, and the kaolin clays of Horni Briza in the Plzen Basin supplied the potteries. The school of medicine and the mechanical and electrical engineering colleges were established after World War II. (H. G. S.)

PNEUMATIC CONVEYING is a method of transporting dry bulk (nonpackaged) materials through pipeline systems by the use of negative or positive compressed air power. The negative pressure of air power creates a partial vacuum whereby materials are sucked into and through a pipeline system; hence the term "sucker" given to the earliest pneumatic conveyors. The positive pressure type blows material through a pipeline system by means of expanding compressed air.

The earliest pneumatic conveyor, using the term loosely, was a system used to transport shavings and sawdust from machines of a wood-planing mill to the refuse pile. This system used the planing mill fan, a flat-bladed type,* to suck the sawdust and shavings from the machines into a pipeline, pass the material through the fan, and blow it to the refuse pile. At the end of the 19th century the positive rotary blower, having demonstrated its ability to deliver higher vacuums and pressures, was brought into use for pneumatic conveying systems.

The use of pneumatic conveyors was greatly increased at the beginning of the 20th century, when the countries of Europe were importing large quantities of grain. The large, high-capacity grain unloader, or "sucker," removed grain from ships' holds faster than any previous equipment. Later, pneumatic conveyors were developed to transport not only grains but also dry, powdery materials, nonabrasive as well as abrasive. Modern industries using pneumatic conveyors for transporting dry bulk materials include chemical, plastic, cement, pulp and paper, rubber, and kaolin. Pneumatic conveyors offer certain advantages: they can easily transport material around corners and up an incline; they are clean, safe, and accessible; they have low handling loss or shrinkage; and they reduce labour costs. However, they are restricted in types and sizes of materials they can carry, limited to one-way flow, and require higher capital investment and higher power costs than for mechanical handling equipment.

Vacuum System.—The vacuum system is used today for unloading railroad cars, ships, and barges, and in situations with a multiplicity of pickup points and a single discharge point. Such an arrangement is also used in the process industries to transport material from two or more bins or sources of supply to a single terminal point such as a weigh hopper, mixer, or similar facility.

A typical unloading system is shown in fig. 1. The exhaustor unit (positive displacement blower) is used to create a partial vacuum in the conveying duct as well as a stream of flowing air to carry the material. The material flows into the portable twin-type nozzle located underneath the covered hopper car; it is then conveyed through a flexible hose and steel-pipe conveying duct to the receiving station where it is filtered from the air stream and retained in cloth bags, allowing the clean air to pass through the exhaustor unit to the atmosphere. The material on separation is discharged from the filter through the rotary air lock to the screw conveyor to the storage bins.

FIG. 1.—TYPICAL PNEUMATIC UNLOADING SYSTEM

Pressure System.—The vacuum type of system is excellent for transporting materials from numerous pickup points to a single discharge point, but many industries required materials to be transported from a single pickup point to a multiplicity of discharge points. This called for reversing the position of the power plant of the pneumatic conveyor from the point beyond the pipeline system to the point where conveying was to begin, and resulting in a pressure system. Starting with low pressures, 2 psi (pounds per square inch) to 12 psi, rotary feeders having star-type wheels enclosed in dust- and pressure-tight housings, with minimum clearances between the wheels and the housings, are used to meter and feed the materials into the conveying pipeline. For higher pressures, fluid-solids pumps and pressure tanks (blow tanks) are utilized to blow large tonnages over distances up to 7,600 ft.

Conveying systems using rotary feeders convey both granular and powdered, nonabrasive or mildly abrasive materials, including grains, soft feeds, flour, starch, and many chemicals. For granular abrasive materials, gate locks of the three-gate type are substituted for the rotary feeders. When finely divided abrasive materials such as portland cement or pulverized phosphate rock are to be conveyed, the fluid-solids pump is used.

The fluid-solids pump will handle only pulverized material, at least 60% of which can pass through a 200-mesh screen, 75% through a 100-mesh screen, and all through a 50-mesh screen. The maximum air pressure at which this pump will operate is 45 psi.

Air supply for the conveying system and the pump is usually furnished by a rotary type of air compressor. Through

FIG. 2.—AIRSLIDE® PUMP UNIT

The explanation usually is either extreme individual susceptibility, predisposing disease such as tuberculosis, accidental excessive exposures, hazardous technical innovations, or the potentiating effects of exposure to several different substances. The pneumoconioses have in a few instances affected nonworking persons. Police officers, housewives, and school children have contracted berylliosis from the inhalation of smokestack effluvia, dust from soiled working clothes, or fluorescent lamp phosphors. The lung injury caused by city smog results from the action of chemical agents adsorbed onto carbon particles emanating in industrial operations. The catastrophic deaths at Donora, Pa. (1946), the Meuse Valley in Belgium (1949), and in London (1952) illustrate the disastrous potential of industrial waste products immoderately disseminated into the air of cities.

Causes.—Theories of the causation of pneumoconiosis include tissue injury by mechanical trauma, protoplasmic poisoning, metabolic changes in cells through a disturbance of pH, protein denaturing through piezoelectric and surface molecular forces, immune and antibody reactions, polymerization, and the nonspecific action of submicron particles. No single explanation is universally acceptable. The pathogenic propensity of a number of specific agents has been proved by experimental reproduction of characteristic lesions in animals.

Symptoms.—Pneumoconioses range from innocuous through variably disabling to lethal syndromes. Symptoms are determined by the focus of major lung injury, combinations of lesions, severity and rate of exposure, and infective or other complications. Dominant states include bronchitis, bronchiolitis, bronchiectasis, emphysema, pulmonary fibrosis, and pulmonary hypertension. The main complications, which also determine the mode of lethal outcome in most instances, are cor pulmonale (pulmonary heart disease) with congestive cardiac failure, tuberculosis, pneumonia, pulmonary insufficiency, hemorrhage, lung gangrene, and erosion of a blood vessel, a bronchus, or the esophagus. Remote lesions may also occur; e.g., portal artery obstruction, metastatic tuberculosis, and liver, kidney, or suprarenal failure. Respiratory tract cancer is closely associated with exposures to monochromates, asbestos, beryllium, nickel, arsenic, and radioactive particles.

Diagnosis and Treatment.—Precise diagnosis depends largely on radiography, but so eclectic and diversified are the manifestations of the pneumoconioses that interpretation of the X-rays requires great skill and experience. Advanced physiological studies have contributed greatly to understanding of the associated disability. Final diagnosis, however, often must await histopathological and petrographic confirmation.

Once established, the majority of the severe pneumoconioses are irreversible. Some syndromes may become arrested on cessation of exposure but others, such as silicosis and asbestosis, progress inexorably. Therapy is directed at the alleviation of symptoms such as pain or bronchospasm, support of the failing heart, and treatment of complicating infection. Apart from dust suppression, adequate ventilation, and the use of exhaust equipment, the only effective prophylactic agent against silicosis is inhaled aluminum administered in the form of aerosols of aluminum oxide, hydroxide, or hydroxychloride. Good results have been achieved in cases of berylliosis by means of the chelating agent aurin tricarboxylic acid or by cortisone. No specific therapy is available for other pneumoconioses.

See also DANGEROUS OCCUPATIONS; DUST; INDUSTRIAL MEDICINE; RESPIRATORY SYSTEM, DISEASES OF; SILICOSIS.

(G. W. H. S.)

PNEUMONIA, an inflammation of the lung. Pneumonia was recognized as a disease by the ancients, but no progress was made in the knowledge of it until the time of Leopold Auenbrugger (1761) and René Laënnec (1819), when order was brought into its classification. From then until the bacteriologic era opened, classification depended on the anatomic or clinical features, and adjectives such as lobar, lobular, broncho-, interstitial, pleural, double, central, croupous and catarrhal were used. Other pneumonias were called aspiration, contusion, hypostatic or terminal pneumonias, depending upon the cause. Although after 1880 various bacteria and viruses were known to cause pneumonia, the modern

etiologic classification did not become popular until about 1930. Precise knowledge of the bacterial or other cause permits the use of specific therapeutic or preventive measures and other rational management in the control of the disease. More than 50 different infectious, physical or chemical causes of pneumonia were known by the second half of the 20th century, but of these, relatively few were of common occurrence. Pneumonias may be grouped as follows: (1) primary, i.e., those caused by pathogenic cocci, bacilli, viruses and fungi that attack the lung primarily; (2) pneumonias that occur in more or less specific forms as part of systemic infections such as tularemia, psittacosis, tuberculosis, rheumatic fever, rickettsial and protozoal diseases, lupus erythematosus and others; (3) pneumonias caused by mixed infection induced by physical or mechanical injury of the lung such as shock, debility, passive congestion, aspiration of foreign bodies of fluid, obstruction to airway, atelectasis, trauma and others; and (4) pneumonias caused by the aspiration of oil, chemicals or dusts, by exposure to roentgen rays, by allergic reaction and other causes.

Pneumococcal Pneumonia.—The modern era of this disease began with the discovery of the pneumococcus in 1880 by G. M. Sternberg and its association with pneumonia by A. Fraenkel and A. Weichselbaum in 1884. F. Neufeld first pointed out serologic differences among strains of pneumococci in 1910, and shortly afterward F. S. Lister and A. R. Dochez independently classified them into types. Much fundamental work on the bacteriology, etiology, pathogenesis, clinical aspects and treatment of pneumococcal pneumonia was done after 1911 at the Hospital of the Rockefeller Institute under the leadership of Rufus Cole and Oswald Avery. Extensive bacteriologic, clinical and epidemiologic contributions on the subject were also made, notably by Russell Cecil, O. H. Robertson and Maxwell Finland in the United States and by H. Loeschke and Max Gundel in Germany. Specific immune serum for treatment reached its greatest effectiveness and popularity as the refined, concentrated form, only to be displaced by the sulfonamide compounds after 1935 and by penicillin in 1942.

Etiology.—There are about 75 types and subtypes of pneumococci, of which only a few are of clinical importance. Types 1, 2, 3, 4, 5, 7, 8 and 14 account for about 80% of all pneumococcal lobar pneumonias. The rest are caused by pneumococci of other types that, in contrast with those mentioned, often are present in the throats of healthy persons.

Pneumococci rarely are primary invaders of the lung. In almost all instances there is evidence of some preceding condition that injures the lung and favours invasion, especially minor infections of the respiratory tract commonly called colds; chilling of the body, and debilitation. The pneumococci that become invasive are acquired by inhalation from outside sources or are already present in the pharynx; the first circumstance indicates that pneumonia may be a contagious disease contracted from other patients or carriers of pneumococci, and the second that it may arise as an autogenous infection. Under certain conditions when the general resistance is lowered by serious conditions, and in old age, the pneumonia is apt to be atypical or lobular (bronchopneumonia); in other words, it does not behave like the lobar form. The onset is gradual, pulmonic solidification may not occur and the course is irregular. The pneumococci causing this form are usually of the higher numbered types, indicating that they are part of the normal flora of the respiratory tract and have become invasive.

Pathology.—Pneumococci reach the lung by way of the air passages, settle in an area where they find circumstances suitable for growth and give rise to an area of inflammation conditioned by complex factors, among which partial immunity, allergy and nervous influences seem to play an important role. The inflammation spreads rapidly and soon involves part or most of a lobe, first as congestion and then with an outpouring of fibrin and polymorphonuclear leukocytes into the alveolar spaces. The exudate becomes rather solid and grayish over a period of several days, and finally, when recovery occurs, it softens and is resorbed. Pneumococci often enter the blood stream and may localize on the valves of the heart, the meninges or elsewhere. The pleura may be invaded, resulting in empyema.

Epidemiology.—Pneumococcal pneumonia is contagious at times, but susceptibility to infection is largely controlled by the resistance of the host. The prevalence of pneumonia usually parallels the incidence of minor respiratory tract infections. Both are most common in cold months but may occur at any season. Household and institutional epidemics have been recorded. Pneumonia varies in incidence from year to year and to some extent in its clinical manifestations, depending on the type of pneumococci predominant at the time. It is most prevalent in the temperate climates but may occur anywhere. All races are susceptible. Men are affected more often than women because of greater exposure. It is commonest in early adult life. Pneumococcal pneumonia declined in incidence after 1900. Yet in 1960 pneumonias were the sixth most important cause of death in the United States.

Clinical Features.—Lobar pneumonia is a strikingly clear-cut disease. It often develops in a person who has a cold and begins suddenly with a chill, pain in the chest, high fever, cough and thick rusty sputum. These are present in variable combinations and constitute the chief features. Other symptoms and signs are headache, vomiting, rapid respiration, cyanosis, dyspnea, tachycardia and herpes. The course in untreated patients may last a week or more, during which severe illness occurs. Characteristic signs in the chest in the early stage are those of congestion changing to those of consolidation of a lobe or lobes with dullness, bronchial breathing, bronchophony, egophony, pectoriloquy and occasionally friction sounds. Roentgenography is of great aid in observing the location and course of the pulmonary lesion. In patients who develop pleural effusion or empyema, signs of fluid appear. The leukocyte count and sedimentation rate of red cells usually are increased and the blood culture often becomes positive. In certain patients the onset is gradual and the course is not so characteristic, giving an atypical clinical response.

In those who recover, improvement often begins abruptly as a crisis with rapid fall of temperature and general improvement unless other involvement occurs. Death is caused by toxemia, overwhelming infection, circulatory collapse or extrapulmonary localization, the chief of which are empyema, meningitis, endocarditis and arthritis. In patients treated with penicillin or sulfadiazine the course usually is terminated within 24 to 48 hours.

The mortality rate is 30% in untreated patients and about 5% in those treated with antibiotics. Five per cent is probably a minimum rate, since there are instances in which therapy is unsuccessful or for various reasons may be delayed or is not available. The disease is more often fatal in infants, debilitated or senile patients or in those with other chronic disease such as diabetes, hypertension or nephritis, or when treatment is postponed. Overwhelming infection that does not respond to any treatment may occur.

One attack of pneumonia does not necessarily predispose a person to another. There are certain persons who, for unknown reasons, have repeated attacks of pneumonia caused by the same type or by different types of pneumococci, or by other bacteria. There is some evidence of a hereditary tendency to the disease.

Diagnosis should be established by clinical, roentgenologic and bacteriologic methods. Material for tests must be obtained before treatment is begun.

Treatment.—Penicillin should be given promptly by injection or by mouth daily until the temperature becomes normal and for several days afterward. Tetracycline, erythromycin, chloramphenicol or sulfadiazine may be used if penicillin is unavailable or if the patient is sensitive to it. Appropriate symptomatic treatment must be given.

Prevention.—The fundamental measures of prophylaxis are the prevention of minor respiratory tract infections and other conditions that predispose to pneumonia and the control of carriers of pneumococci. The maintenance of general health by adequate food, exercise and rest is important. Specific vaccines consisting of pneumococcal polysaccharides are of practical advantage only among well-controlled groups.

Hemolytic Streptococcal Pneumonia.—This form of pneumonia is less common than the pneumococcal forms and occurs often as a complication of influenza, as it did in the pandemic of 1918. It is caused by any of the 27 or more types of group A beta

hemolytic streptococci. It may occur in sporadic or in epidemic form, the latter depending on the prevalence of a predisposing viral infection. The bronchi and trachea are involved more often and more severely than in pneumococcal pneumonia. There is lymphangitis and involvement of interstitial tissues. The exudate is thin and hemorrhagic, and streptococci are numerous. The pleura is usually inflamed.

The symptoms are not characteristic. The disease begins as an aggravation of the mild primary disease. There are fever, cough, pain in the chest, chills or chilly sensations and prostration in widely varying degrees of severity. The sputum is thin, mucopurulent and bloody. Bacteremia is uncommon. The leukocytes may be normal or increased in number. Massive pleural effusion with serosanguineous fluid or empyema are common. The patient may be mildly sick or extremely so with ashy pallor, cyanosis and evidence of circulatory collapse. The pulmonary signs are chiefly those of atypical pneumonia with patchy areas of congestion and areas of undeveloped consolidation.

The mortality rate in untreated patients varies from 10% to 60%; not enough patients have been treated with penicillin or sulfadiazine to judge their beneficial effects.

The diagnosis is made chiefly by the epidemiologic characteristics of the disease and by the predominance of hemolytic streptococci of group A in the sputum, blood or exudate. Retrospective diagnosis may be made by the demonstration of specific precipitins, antistreptolysin and antifibrinolysin in the blood. Roentgenography is useful in determining the nature and extent of the pulmonary lesions. Penicillin is indicated and must be given in large dosage. Sulfadiazine is said to be of some value. The symptomatic treatment is the same as for other pneumonias. Pleural effusion should be aspirated repeatedly and, if empyema is present, penicillin may be injected into the cavity.

Staphylococcal Pneumonia.—The staphylococcus, like the hemolytic streptococcus, invades the lung particularly during minor viral infections of the respiratory tract. Staphylococcal pneumonia occurs sporadically or in epidemic form during epidemics of viral diseases of the respiratory tract. Many cases occurred in the influenza pandemics of 1918 and 1957. In recent years, it has increased in incidence due to the overuse of antibiotics. Corticosteroids and radiation therapy given for other diseases lower resistance and favour the invasion of staphylococci. The causative staphylococci usually are those present normally in the patient but they may be acquired from outside sources. Their invasion gives rise to patchy areas of inflammation in the lungs. In the course of several days, multiple small abscesses form and tend to coalesce.

The symptoms usually begin gradually. They vary greatly in intensity from mild to severe with high remittent fever, chills or chilliness, sweating, cough, cyanosis, prostration and purulent sputum. The leukocyte count is variable and bacteremia seldom occurs. When abscesses form and discharge through the bronchi, the sputum increases in amount and the signs change from those of patchy pneumonia to those of cavitation. The mortality rate is variable; in some cases studied, most patients recovered and in others 70% died.

Diagnosis is based on the epidemiologic aspects of the disease; the presence of great numbers of staphylococci in the sputum, exudates or the blood stream; and the signs and roentgenographic evidence of the development of multiple cavities.

Penicillin is the agent of choice, but it must be given in large amounts parenterally. Synthetic penicillins, novobiocin and vancomycin are specific for staphylococci.

Klebsiellar (Friedländer's Bacillus) Pneumonia.—This infection occurs chiefly in debilitated or senile persons. The onset often is like that of pneumococcal pneumonia. The disease is characterized by a severe course, irregular fever, occasional abscess formation but less evidence of firm consolidation of the lung than in pneumococcal pneumonia. The sputum is bloody, mucinous or mucopurulent and its bacteriologic content consists predominantly of capsulated gram-negative coccobacilli. A chronic form with cavitation resembling tuberculosis may ensue. Because the infection occurs chiefly in weakened persons, the mortality rate is high (about 50% to 70%). The treatment is not so effective as

for other forms of pneumonia. Antibiotics must be selected according to the sensitivity of the bacilli; they are used in large dosage singly or in combination.

The Viral Pneumonias.—While much attention had been given to the serious bacterial pneumonias, little was paid prior to about 1920 to those of viral origin, chiefly because they seldom caused death and the technique of identifying viruses was undeveloped. It had been known since 1861 that viral diseases such as measles are characterized by pulmonary involvement, but the nature of the pneumonia was obscured by the activity of secondarily invading bacteria. Because of this, the pneumonias that occur during severe colds also were regarded as complications caused by bacteria, although they rarely are. However, the experimental production of pneumonia in animals with the viruses of influenza and vaccinia, and the absence of bacteria in the pneumonic lungs of patients who died during the pandemic of influenza in 1918, left little doubt that viruses do cause pneumonia. Between 1920 and 1938 European and U.S. roentgenologists demonstrated unsuspected pneumonias in many patients with mild, acute respiratory tract infection.

In 1938 Hobart A. Reimann established viral pneumonias as entities and demonstrated their occurrence as the severest forms in 5% to 10% of epidemic viral minor respiratory tract infections. Specific nosography became possible later after the discovery of a number of causative viruses in addition to influenza viruses, namely, adenoviruses, Coxsackie, ECHO (enteric cytopathogenic human orphan), reo-, respiratory syncytial and myxoviruses. Each of these causes epidemics of mild disease with occasional pneumonias. Other agents that are not true viruses, such as the Bedsonias (psittacosis, ornithosis) and mycoplasma (Eaton agent), cause similar disease. Viral pneumonias, in general, outnumber those caused by bacteria. Their incidence varies from year to year depending upon the epidemic prevalence of the respective viral infections, of which they are the severe forms.

The symptoms are similar for each entity. As the mild infection worsens, headache, dry paroxysmal cough, slight sore throat, sweating, chilliness and irregular fever develop although there are few or no abnormal physical signs in the lungs. Roentgenography, however, may reveal extensive infiltration. Later, dullness to percussion, suppressed breath sounds and *râles* appear. The leukocytes may increase slightly in number. The pneumonia often is so mild as to be unsuspected but may be severe with dyspnea, cyanosis and prostration. It may last a week or more. Complications are rare. The mortality rate is less than 1%. Death usually is caused by circulatory failure, especially in patients debilitated by other conditions. Pathologically, parts of or all of the respiratory mucous membrane is inflamed with but little exudate. The interstitial tissues of the lungs are inflamed and invaded by monocytic cells. The lesions disappear slowly.

Diagnosis is made by the epidemiologic aspects, the clinical behaviour, the low leukocyte count and the absence of pathogenic bacteria in the sputum. Etiologic proof depends upon the isolation and identification of the causative viruses and serologic evidence of their activity. It is of importance to diagnose pneumonias caused by the Eaton agent (mycoplasma) and of psittacosis and ornithosis (Bedsonia) that respond to antibiotic therapy. The same is true for the pneumonias of tuberculosis, Q fever and others that resemble viral pneumonias.

Antibiotics now available have no therapeutic value for viral pneumonias. The treatment is symptomatic for the relief of headache, aching and cough.

Miscellaneous Primary Agents.—Rarer forms of pneumonia are caused by *Hemophilus influenzae*, *H. pertussis*, *Bacillus anthracis*, *Pasteurella pestis*, *P. tularensis*, *Gaffkya tetragena*, *Histoplasma capsulatum*, *Coccidioides immitis*, *Coxiella burnetii*, *Toxoplasma*, *Mycoplasma*, *Pneumocystis carinii*, *Bedsoniae* and others.

Pneumonias of Systemic Diseases.—Pneumonia may occur as an integral part of many systemic diseases. It may dominate the clinical picture, or it may be a minor factor or not occur at all in tuberculosis, tularemia, plague, undulant fever, glanders, syphilis, rheumatic fever, ascariasis, polyvasculitis, sarcoidosis and many

others. The pneumonia usually is not characteristic clinically and often is obscured by symptoms of the systemic disease. Pathologically it may assume features characteristic of the respective disease. The treatment is that of the primary disease.

Pneumonias of Mixed Infections.—The pneumonias brought about by injury to the lungs or interference with their self-cleaning process usually are caused by a mixture of various kinds of bacteria that reside habitually in the air passages and are enabled to become invasive by the presence of injured tissue. The injury or interference of the cleaning action may be caused by obstruction of the airways by foreign bodies or tumours, failing circulation, submersion in or aspiration of fluids, trauma, atelectasis after surgical operation, shock and many other causes. Pneumococci, influenza bacilli, hemolytic streptococci and staphylococci are most frequently implicated. The iatrogenic reduction of bodily resistance by corticosteroids, radiation and other agents has increased the incidence of pneumonias caused by gram-negative bacilli and fungi. The treatment is directed primarily to the control or removal of the underlying cause. Antibiotic agents are given according to the sensitivity of the invading bacteria or fungi to the respective drugs, and appropriate supportive measures are applied.

Pneumonias Caused by Noninfective Agents.—The aspiration of oil over long periods or in large amounts often causes a chronic reaction commonly called lipid pneumonia. Long exposure to roentgen rays may give rise to a pulmonary reaction called irradiation pneumonitis that leads to fibrosis. The inhalation of irritating chemicals (silo filler's disease), dusts (farmer's lung, byssinosis, bagassosis, berylliosis) and toxic gases used in warfare or industry, or fumes from certain molten metals may cause forms of pneumonia. Allergic pneumonitis or Löfller's syndrome represents the hyperergic inflammatory reaction of sensitized pulmonary tissue to repeated exposure to a specific antigen. The prevention and treatment of each of these conditions is the removal of the offending agent.

PNEUMOTHORAX, the presence of free air in the pleural space (i.e., between the chest walls and lungs), which normally contains no air. Air may be introduced into the pleural space as the result of trauma, by spontaneous rupture of the visceral pleura or by means of a needle inserted through the chest wall.

The chest is divided into two airtight compartments by the mediastinum. A thin membrane called the pleura covers each lung and is reflected at the root of the lung to form the lining of the inner surface of the chest wall. Normally the visceral pleura (covering the lung) is in contact with the parietal pleura (covering the inner surface of the thorax) and the potential space between them is spoken of as the pleural space. A pneumothorax exists if the two layers of pleura are separated by air and the lung collapses away from the chest wall. Usually, the pleural rent heals spontaneously and re-expansion of the lung follows as the air is absorbed. In some cases, the air must be removed by needle or rubber catheter to aid breathing or speed recovery. In special cases, surgery is necessary.

Traumatic Pneumothorax.—Since the lung is an elastic organ and tends to be pulled toward the lung root, the pressure in the pleural space is less than atmospheric, averaging minus five centimetres of water. This means that air under atmospheric pressure will be sucked into the pleural space if the visceral pleura is torn (e.g., by a fractured rib) or if an open wound in the chest wall penetrates the parietal pleura. If a "sucking wound" of the chest wall exists, more air may be pulled into the pleural cavity via the wound than is pulled into the lung via the larynx, with the result that the collapsed lung and mediastinum are pushed toward the healthy side on inspiration and away from it on expiration. This paradoxical motion of the lung and mediastinum causes progressive asphyxia unless the wound is closed.

Spontaneous Pneumothorax.—The sudden collapse of the lung without previous trauma, termed spontaneous pneumothorax.

is usually accompanied by severe chest pain and difficulty in breathing. Most cases occur in apparently healthy persons. Because spontaneous pneumothorax may occur as a complication of pulmonary tuberculosis, it was assumed for years that almost all cases were due to tuberculosis. This is not true.

In 1932 H. Kiaergaard suggested the emphysematous blebs in the pleural surface of the lung were the common cause of spontaneous pneumothorax, and this concept was later confirmed. Superficial blebs on the pleural surface are weakened areas of pleura; they may blow out as a result of suddenly raising the intrapleural pressure by lifting, coughing or laughing. When spontaneous pneumothorax tends to recur it can usually be successfully treated surgically.

Artificial Pneumothorax.—In 1882 Carlo Forlanini first reported the successful use of artificial pneumothorax in the treatment of pulmonary tuberculosis and until recently the procedure was used extensively in the treatment of that disease. However, after both the introduction of several highly effective antituberculous drugs in the 1940s and the perfection of thoracic surgery for the resection of the diseased portions of the lung, its therapeutic use was drastically reduced. It has no value in the treatment of other pulmonary diseases.

PO (the ancient **PADUS**), Italy's longest river, rises in the Monte Viso group of the Cottian Alps on Italy's western frontier, and in its uppermost course is a rapid and precipitous stream, descending about 5,500 ft. (1,675 m.) in its first 22 mi. (35 km.). Just west of Saluzzo the Po turns sharply northward, flows through Turin (Torino) and skirts the Monferrato upland, then turns east at Chivasso and continues in a generally easterly course to its delta on the Adriatic. Having received the waters of the Dora Riparia and the Dora Baltea below Turin, the Po has as its principal tributaries the Sesia, Ticino, Adda, Oglio, and Mincio from the north, these contributing most of the river's waters. Among the numerous streams that drain into the Po from the south, the Tanaro (from the Maritime Alps), and the Scrivia and Trebbia (from the Apennines) are important, but many of the others are torrential and carry little water through much of the year.

The length of the Po from its source to its delta, when all meanders are taken into account, is 405 mi. (652 km.). The basin of the river covers 27,062 sq.mi. (70,091 sq.km.). Throughout its middle and lower course, especially downstream from the Sesia confluence, the Po describes many meanders and has left numerous oxbows. The delta is the most complex of any European river, its geologic history showing at least five distinct phases of development. In the 1960s the delta had 14 mouths, usually arranged in five groups, these being (from north to south) the Po di Levante, Po di Maestra, Po della Pila, Po delle Tolle, and Po di Goro e di Gnocca. Of these mouths, the Po della Pila carries the greatest volume of water and is the only navigable one. The river is navigable from its mouth to Pavia. At Pontelagoscuro, 60 mi. from the sea, the average discharge of the Po is 58,800 cu.ft. per sec., with variations from 910 to 340,000 cu.ft. per sec., although in the great flood of 1951 the discharge in the lower river was estimated at 424,000 cu.ft. per sec. The most devastating floods of the Po during the Christian era have been those of 589, 1150, 1438, 1882, 1917, 1926, 1951, 1957, and 1966, all of them in the autumn.

The silt load carried by the river is considerable, and the extension of the delta is estimated at 200 ac. per year. Certain ancient ports south of the delta, such as Ravenna, now find themselves as much as 6 mi. from the sea, as a result of silt from the Po carried down by currents in the Adriatic. The floods of the river and the silt load carried by it have long challenged hydraulic engineers. The Venetian Republic built dikes to control floods and canals to divert silt, and in the area between Ferrara and the Adriatic numerous undertakings have reclaimed thousands of acres during the past three centuries. The most recent of these projects, undertaken in 1953 by the Italian Land Reform, was devoted to soil improvement, reclamation of marshy areas such as the *valli*

("marshes") of Comacchio, and the creation of small peasant farms in the delta area, or Polesine, an area that nevertheless suffered enormously in the great floods of 1951 and 1966.

The lower valley of the Po was at an early period occupied by people of the Paleolithic and Neolithic stages of civilization, who built houses on piles along the swampy borders of the streams. The river regulation works originated in pre-Roman times. The reclaiming and protecting of the riparian lands went on rapidly under the Romans, and in several places the rectangular divisions of the ground are still distinct. (See **ESTE**.) During the barbarian invasions much of the protective system decayed but the later Middle Ages saw the works resumed, so that the present arrangement existed in the main by the close of the 15th century.

The Ligurian name of the Po was Bodincus or Bodencus; i.e., the bottomless. The name Padus was taken from the Celts or the Veneti. Thus Bodincomagus is found as a town name on the upper course, and Padua as a name of one of the mouths of the river.

See A. Cappellini, *Il Polesine* (1925); J. Popescu et al., "The Po," in *Rivers of the World* (1962).

(G. KH.)

POACHING, the stealing of game or fish from land or stretches of water either privately owned or where the shooting, trapping, or fishing rights are specially reserved. Until the 20th century most poaching was subsistence poaching, the taking of game by impoverished peasants to augment a scanty diet. In medieval Europe feudal landowners, from the king downward, stringently enforced their rights and special laws protected the vast "forests" reserved as royal hunting grounds. Because England was a highly centralized and strongly governed kingdom, a vast amount is known of the working of its forest laws; and for this reason the account of forest and game laws given in the historical sections of this article is based on conditions in England. It may be assumed that landlords in other countries made similar attempts to protect their rights and that poachers equally sought to infringe them.

(X.)

Poaching in Medieval Times.—In England, under the Norman kings, large stretches of the countryside were subject to a special law of the forest, intended to preserve the beasts of the chase, the red, fallow, and roe deer, and the wild boar for the king's hunting. The greatest men in the land could hunt in a royal forest only with his permission. The justification for these laws was the need to provide the king with sport, his household with meat, and his government with timber for domestic and defensive building. The royal forests were at their greatest extent under the Norman kings and thenceforward there was continuous conflict between the king, who wished to maintain or extend the area under forest law, and his subjects, who wished to reduce it. The readiness with which the barons, knights, and freemen of a shire combined to secure disafforestation meant that the king could raise considerable sums by selling exemptions from forest law. The extensive forest concessions won by the barons from King John in Magna Carta (q.v.) were expanded into a Charter of the Forest in 1217.

Pressure of population gradually eroded the actual area of afforested land. Assarting (ploughing up for crops) reduced the area covered by trees and underwood. Hunting and poaching reduced the animal population. Wild boars were almost exterminated by 1250 and the roe deer ceased to be protected in Edward III's reign because it was said to drive away the other deer. Hares, rabbits, and cats, "beasts of warren," were never protected and the king readily gave landowners permission to hunt them because they disturbed the forest beasts and encroached on their food. Occasionally the king granted a forest to a favoured subject who then had within it all royal rights in regard to hunting and timber and the holding of forest courts. Magnates often enclosed areas of their estates as "parks" for their own hunting, but if these parks were near a royal forest, royal permission was necessary for their enclosure.

Up to 1238 forest law was administered under the ultimate authority of a chief justice of the forest, but in that year England was divided at the River Trent into two regions, each under an officer called a justice or a warden. Under them were wardens, and in each forest generally four verderers, who sat in the at-

tachment courts held every six weeks to deal with those accused of forest offenses. The swanimote court was held in each forest three times a year to regulate the use of the woods within the forest. In the Charter of the Forest (1217), the king promised that "in future no one shall lose life or limb for our venison" (cap. 10), but it remained a serious crime to kill a forest beast. An inquest was held, and the guilty, if found, was imprisoned to await trial. Outside the forest such beasts could be freely hunted provided the king had not granted hunting rights to a subject. But the area of wild country in which the common man could hunt was constantly diminishing. Nevertheless, the forest law was probably more hated by the landowner who could not freely hunt in his own woods than by the humble inhabitants of a forest who enjoyed special rights of collecting deadwood and pasturing their animals. Inherited cunning in the ways of birds, beasts, and fish often helped them to avoid detection in seeking illicit rewards from within the king's forests. (D. M. S.)

The 16th–20th Centuries.—Cumulative destruction of forests, enclosure of wastes, and taking of communal land into private use constituted a long process stretching over several centuries, but as it continued, particularly in the 18th and early 19th centuries, the scope and scale of poaching changed. Private owners of land resented what they thought of as a growing threat to the security of their property and introduced special legislation in the form of game laws. In England, by an act of Charles II (22 & 23 Car. II, cap. 25) it was illegal for anyone to buy and sell game, with the result that prices obtained by well-organized poachers could often stimulate illicit trade. It was also illegal for anyone who was not a squire or a squire's eldest son to kill game even if invited by the owner. During the 18th century the practice of protecting property by gamekeepers increased, although it was claimed that some at least of the gamekeepers were poachers themselves, "taking one brace for the master and two for themselves." Poachers were confronted on the spot by gamekeepers, and in the courts, as the game laws became more severe in the reign of George III, by justices of the peace who were often the owners of the land on which they had been poaching. Farmers were often said to be more sympathetic to poachers than landlords, but the poaching "game" as a whole became far more serious, with landlords and squires insisting on their game rights as a matter of social privilege and with poachers resenting them for this reason.

During the privation years of the late 18th and early 19th centuries, when population was rising sharply, food prices were high, and rural labourers were losing something of their independence, poachers frequently joined together in organized gangs. Fierce battles frequently ensued between gangs and gamekeepers, with shotguns being used at close range and with man-traps and spring guns being placed in brushwood to catch intruders. Transportation was the most severe penalty, one which sympathetic juries were loath to impose, and it is partly because of memories of the severity of this punishment that in Australia bushrangers and cattle thieves became popular heroes. In the United States, where game rights and social privileges were not associated, there was no such hero worship. Although the social exclusiveness of landowners' shooting rights disappeared in England with the Game Act of 1831, it remained in Scotland and Ireland, where poaching was a familiar offense throughout the whole of the 19th century. Nor did a provision in the act of 1831 allowing persons holding game certificates to sell game to persons licensed to deal remove economic incentives to poach for the market. In the long run changes in society and forms of behaviour made poaching offenses a less important element in national crime statistics. Throughout the 19th century attitudes toward poaching remained conditioned by social factors. Landlords emphasized the correlation between poaching and other kinds of social misbehaviour. Opponents of the landed interest identified game laws and corn laws and described both as attempts to protect an antisocial monopoly. Without openly supporting individual poachers, they bitterly attacked "braces of sporting justices." The views and practices of landlords and squires were compared with those of pre-Revolutionary France and the most backward parts of 19th-century feudal Eu-

rope. Humanitarians related the incidence of poaching to rural distress and sought to suppress cruel and excessive punishments. On the continent of Europe poaching history was directly related to the history of feudalism; with the abolition of feudalism in France and the diffusion of peasant ownership, poaching became a more specialized activity. (A. BRI.)

Poaching in the Mid-20th Century.—Subsistence poaching largely died out after World War II because living standards rose. Exceptions existed in some parts of eastern Europe where occasional hunger continued to cause peasants from time to time to defy their countries' game laws, and in Africa where illegal killing of horned game for meat remained a problem for conservationists. Elsewhere poaching continued for other reasons. In western Europe and North America the two most powerful remaining incentives to poaching were the commercial profits from large-scale raids by organized gangs and the daredevil aspect of small-scale operations motivated by defiance of the law as well as the desire for sport. Because of the larger concentrations of game there, particularly of winged game, commercial poaching was most highly developed in Britain. The usual method was for car-borne gangs of six or eight men to invade by night the game-holding coverts of properties not less than 100 mi. from their town bases. As many as 500 pheasants in a night were sometimes stolen, thanks to careful prior reconnaissance, generally by an informer maintained on the spot, perhaps in the guise of a visiting workman. The very high price of salmon early in the open season led to much highly organized river poaching. Generally this was carried out by stunning fish by underwater explosions or by poisoning a river with some asphyxiating agent that kills the fish without harming the flesh. So serious did this poaching become in Scotland that in 1951 the Labour government passed an act drastically increasing the maximum fine for offenses, providing for prison sentences, and authorizing the confiscation of equipment found in the offenders' possession. Pressure continued for the extension of this law to the rest of the United Kingdom. In North America, where the main anxiety was the salmon stock of some rivers near large cities, efficient patrolling by game wardens held market-killing in check. (W. S.)

POBEDONOSTSEV, KONSTANTIN PETROVICH (1827–1907), Russian jurist, civil servant, and political philosopher who exerted a profound reactionary influence on Russian domestic policy from 1880 to 1905, was born in Moscow on Dec. 12 (new style; Nov. 30, old style), 1827. After being educated at home by his father, a professor of Russian literature at Moscow University, Pobedonostsev received training in law in St. Petersburg. He returned to Moscow in 1846 to enter the bureaucracy. A number of articles on the history of Russian law which he published in the late 1850s won him a position as lecturer in Russian law at Moscow University in 1859, and he was soon thereafter named tutor in Russian law and history to the emperor Alexander II's children. His work as a historian of Russian law led him to become an advocate of judicial reform, and from 1861 he participated in preparing the judicial reforms issued in 1864. Gradually, however, he turned against all the reforms of Alexander II, particularly that of the courts. His service as one of the tutors and closest advisers of Alexander III helped make the latter a most reactionary ruler.

Pobedonostsev moved to St. Petersburg in 1865, was nominated to the senate in 1868 and to the council of state in 1872, and became *oberprokuror*, or lay head, of the Holy Governing Synod of the Russian Orthodox Church in 1880. This high position in the government and his great influence over Alexander III and Nicholas II gave Pobedonostsev immense power, which he used in domestic policy, particularly in matters affecting religion, education, and censorship. He was to a large extent responsible for the government's repressive policy toward religious and racial minorities and those who wanted to make Russia more like a Western European state. His influence declined gradually after 1895, but he was so unpopular that he was called the "Grand Inquisitor" and became the symbol of the old regime for all who wanted radical or revolutionary change. He was retired from office during the revolution of 1905.

Pobedonostsev's deep hatred and fear of constitutional and democratic government, freedom of the press, religious freedom, trial by jury, and free lay education was best expressed in a collection of essays, *Moskovski Sbornik* (1896), which has been translated into several Western languages, as also have many of his letters. His three-volume study of Russian civil law, *Kurs grazhdanskogo prava* (1868–80), went through several editions and was praised for its careful scholarship. He was a man of great learning, traveled frequently in Western Europe, and spoke many Western languages. He was a close friend of Dostoevski in the 1870s and was highly respected as a scholar and critic before his rise to high state positions. A man of powerful religious fervour, he was especially interested in primary religious education. Pobedonostsev died in St. Petersburg on March 23 (N.S.; 10, O.S.) 1907.

POCAHONTAS (c. 1595–1617), daughter of the North American Indian chief Powhatan and heroine of one of the best-known traditions of early American history. As a young girl she was very helpful to the settlers of the Jamestown colony. In April 1613 she was kidnapped by one of the settlers, Samuel Argall, who hoped to use her to negotiate permanent peace between her tribe and the Virginians. While living in Jamestown she was instructed in Christian doctrine and baptized Rebecca. She married John Rolfe, who introduced the cultivation of tobacco in Virginia. In 1616 the governor of the colony, Sir Thomas Dale, seeing in the adaptable Indian princess an advertisement for the London Company of Virginia, took her and her husband to England, where she was received at court and lionized by London society. On the return voyage she died and was buried at Gravesend. Her one son, Thomas Rolfe, later came to America and settled in Virginia.

Pocahontas' popular fame derives from a story told by Captain John Smith (*q.v.*), one-time leader of the Jamestown settlers. In a letter to the queen at the time of Pocahontas' arrival in London, Smith related that he had been captured by Powhatan's men and was to be put to death; but just as he laid his head on the sacrificial stone and was awaiting death, Pocahontas embraced him and begged her father to spare him. Although this story is consonant with Indian custom and has never been refuted, Smith's habit of self-dramatization and the fact that he failed to include the story in his first account of the Virginia colony (1608) have led some historians to doubt its authenticity. (M. E. Yo.)

POCATELLO, a city of southeastern Idaho, U.S., the seat of Bannock County, occupies a mountain valley (elevation 4,460 ft. [1,359 m.]) at the mouth of Portneuf Canyon about 15 mi. (24 km.) from the Snake River. Settled in 1882 during railway construction and named for an Indian leader friendly to the whites, Pocatello grew slowly at first because of its location on the Fort Hall Indian Reservation. But its strategic position as a major railway junction brought important Union Pacific shops there in 1887; with the opening of the Fort Hall Reservation to settlement in 1902, Pocatello grew rapidly and became the most prominent railway centre on the Union Pacific between Omaha and Portland. The Academy of Idaho was established in Pocatello in 1901 and began instruction at college level in 1927; the name was changed to Idaho State College in 1947 and to Idaho State University in 1963. Expansion of nearby irrigation helped the city to become a wholesale distributing centre with a variety of manufacturing and agricultural processing plants. An army air base reverted to a municipal airport after World War II, but the community expanded industrially with the acquisition of a large naval ordnance plant in 1942 and of important phosphate reduction works in 1946. The city has a council-manager form of government, in effect since 1951.

For comparative population figures see table in IDAHO: Population. (M. D. B.)

POCHARD, a diving duck (*Nyroca ferina*), the female of which is sometimes called the dunbird. In the male in full plumage the head is coppery-red, the breast black, and the back and flanks a dull white, closely barred with fine undulating black lines. The

tail coverts and quill feathers are black and the lower surface dull white. The female is duller. The pochard breeds throughout the northern hemisphere, migrating to the coast in winter and retreating southward. The American subspecies is larger. A second American species is the much bigger canvasback (*q.v.*) duck. Both species are excellent table birds when they frequent fresh water, the canvasback being preeminent.

PO CHÜ-I (A.D. 772–846), one of the outstanding poets of the T'ang period in China, was born at Hsin-cheng in 772. He came of a family of minor officials and rose to high posts in the civil service, entirely owing to his literary talents. In 800 he did well in several examinations at Ch'ang-an (Sian), the capital, and in 806 he obtained a minor post at a small place near Ch'ang-an. In the next year he was summoned to Ch'ang-an and became a member of the Han-lin academy. In 811 his mother died and he fulfilled his mourning at a village to the east of the capital. He returned to court in 812 and took an active part in politics. In 814 he was suddenly relegated to a minor post at Kiukiang (Chiu-chiang), on the Yangtze River. What led to this banishment is far from clear. Po himself regarded it as due to the jealousy of senior statesmen over whose heads he had been promoted. In 818 he became governor of Chung-chou, high up the Yangtze. When in 820 a new emperor came to the throne, Po was recalled to the capital, where he resumed his previous task of composing imperial letters and rescripts. In 822 he became governor of the important town of Hangchow and then of Soochow. He was summoned back to the capital in 827 and became head of the imperial library. In 829 he settled permanently at the eastern capital, Lo-yang, and in 831 became mayor of the city. In 833 he retired from this post owing to illness and lived uneventfully at Lo-yang till 839, when he had a paralytic stroke, from which he never fully recovered. He died there in the autumn of 846.

There were in Po's day no organized political parties, but there was a loose cleavage between those who rose owing to family influence and those who made their way to the top solely by literary eminence and success in examinations. Po Chü-i belonged to the latter class and was at loggerheads with some of the most bigoted members of the aristocratic clique. But no hard and fast line divided the two groups and some of his best friends were in the opposite camp. Two outstanding features of his life were his devotion to Buddhism and his friendship with Yüan Chen, one of the most famous friendships in Chinese history. See also CHINESE LITERATURE.

See A. Waley, *The Life and Times of Po Chü-i* (1949).

(A. D. Wa.)

POCKET MOUSE, the name of a number of small, mouse-like, western North American rodents belonging to the subfamily Perognathinae of the family Heteromyidae and including several genera, all with fur-lined external cheek pouches. The typical pocket mice (*Perognathus*) are small, with rather long tails and hind feet. They live in deserts and on the Great Plains, feeding on seeds. *Heteromys* and *Liomys*, the spiny pocket mice (subfamily Heteromyinae), have bristles mixed in the coat. They are dark gray or blackish in colour. Most species of these two genera are Central American, extending to northern South America. See also RODENT. (J. E. Hl.; X.)

POCOCKE, EDWARD (1604–1691), English orientalist and biblical scholar, who introduced the study of Arabic at Oxford and collected many valuable ancient manuscripts, was born, the son of a Berkshire clergyman, at Oxford and baptized Nov. 8, 1604. He was educated at Corpus Christi College, Oxford. He served as English chaplain at Aleppo (1630–35) and on his return to England was appointed first professor of Arabic at Oxford, succeeding to the chair of Hebrew in 1648. Pococke discovered in a manuscript at the Bodleian Library at Oxford the missing Syriac versions of the four New Testament epistles (II Peter, II and III John, and Jude) which were not in the old Syriac canon; his edition of these was published at Leiden in 1630. In 1649 he published *Specimen historiae arabum*, a short account of the origin and manners of the Arabs, followed in 1655 by *Porta Mosis*, extracts from the Arabic commentary of Maimonides on the Mishna, with translation and notes. His *magnum opus*—a complete edition

of the Arabic history of Bar-Hebraeus, with a Latin translation, was dedicated to the king in 1663. Pococke died on Sept. 10, 1691.

See L. Twells (ed.), *Theological Works of the Learned Dr. Pocock*, 2 vol. (1740), which contains a biography.

PODEBRADY, GEORGE OF (Czech JIRÍ z PODĚBRAD) (1420–1471), king of Bohemia from 1458, was born at Podebrady, ENE of Prague, on April 23, 1420, the son of Viktorin of Kunstat and Podebrady, a Czech nobleman who was a leader of "the Orphans," or moderate Taborites, in the Hussite wars (see **BOHEMIA**; **HUSSITES**). George early became prominent in the party organized, chiefly by the Utraquist Hussites, to promote the Bohemian national cause; and when Ptacek of Pirkstejn died (1444) he was recognized as its head. Meanwhile the prospective king of Bohemia, Ladislav (the Habsburg Ladislas Posthumus; see **LASZLO V of Hungary**), was still a minor; and in 1448 George, having raised a force of 9,000 men in northeastern Bohemia, where his ancestral castle stood and where his party was strongest, occupied Prague. He subsequently defeated the Romanist or pro-Habsburg (Austrian) party led by Oldrich of Rozmberk; and in 1451 Ladislav's guardian, the future Holy Roman emperor Frederick III, entrusted George with the administration of Bohemia. In the same year a diet at Prague appointed George regent of Bohemia for Ladislav.

When Ladislav began to rule in his own name (1453), George's position became difficult, since the king sympathized strongly with the Catholics in the continuing religious struggle, though he undertook to respect the ancient rights of Bohemia and the *Compactata* or "compacts" whereby the claims of the Utraquists had been acknowledged. Ladislav, however, died suddenly in 1457. Hostile opinion from an early date accused George of having poisoned him; but the charge is undoubtedly false.

On March 2, 1458, the Bohemian estates unanimously elected George as king, even the Romanists voting for him. His rule, however, was obstructed by the hostility of the new pope, Pius II. George refused the pope's demand that the compacts should be abolished, but tried to placate him by measures against the most extreme enemies of the papacy, including the newly founded community of the Bohemian Brethren. Even so, Pius was planning a crusade against Bohemia when he died (1464). Though Bohemia itself prospered under George, malcontent nobles of the Romanist party formed a confederacy against him at Zelena Hora (Nov. 28, 1465), which the new pope, Paul II, supported. On Dec. 23, 1466, Paul excommunicated George and pronounced him deposed from the kingship, forbidding all Catholics to continue their allegiance to him. The emperor Frederick III and George's former ally Matthias Corvinus of Hungary joined the insurgents, and Matthias, having conquered much of Moravia, was proclaimed king of Bohemia at Brno on May 3, 1469. War went on till George died, in Prague, on March 22, 1471.

PODESTA (Latin *potestas*, "power"), the highest magistrate of medieval Italian communes. The emperor Frederick I Barbarossa appointed imperial *podestàs* in most Italian cities under his control (see **ITALY: History**); but from the end of the 12th century onward, *podestàs* elected by the communes themselves gradually superseded the collegiate government of the consuls (see **COMMUNE [MEDIEVAL]**). Normally a nobleman from another city or, sometimes, from a neighbouring feudal family, the *podestà* was at first usually elected for one year, later often for six months. He summoned the councils, led the communal army, and administered civil and criminal jurisdiction. Though the office was subject to strict statutory limitations, it sometimes served as a starting point for the establishment of a despotic government or *signoria*. After the 13th century, it declined in importance; in 15th-century Florence, its principal functions were judicial.

Podestà was the title of mayors in the Austrian territories of Italy from 1815 to 1918; and of mayors appointed by the Italian government between 1926 and the end of the Fascist regime.

Hanauer, "Das Berufspodestato im dreizehnten Jahrhundert," *Mitteilungen des Instituts für österreichische Geschichtsforschung*, 33 (1902); F. Hertter, *Die Podestäliteratur Italiens im 12. und 13. Jahrhundert* (1910).

PODGORICA: see **TITOGRAĐ** (Yugos.).

PODIATRY (**CHIROPODY**) is the healing art concerned with the human foot. The Ebers medical papyrus (c. 1500 B.C.) records foot remedies from earlier centuries. Other references are found in the literature of all succeeding cultures. The word chiropody derives from a 1774 treatise, *Chiropodologia*, by D. Low, of London, where a Dr. Lyons in 1785 applied for a licence limited to practice on the feet. The term podiatry was coined in 1917 by M. J. Lewi of New York.

The first practice act was enacted in New York State in 1895, and by 1938 all the states of the United States, Canada, the United Kingdom, Australia, and New Zealand had licensure provisions. In the United States the National Association of Chiropodists was organized in 1912 and adopted the name American Podiatry Association in 1958. In Great Britain chiropodists function under the national health service. The first college of podiatry was organized in 1912.

Podiatrists diagnose and treat by medical, surgical, and other means diseases and deformities of the human foot; they utilize mechanical devices, special shoes, physiotherapy, pharmaceuticals, and surgery. (A. Ru.)

PODIUM, in architecture, a continuous pedestal, a low wall supporting columns, or the lowest portion of the wall of a building when given a separate architectural treatment. Sometimes the basement story of a classic building may be treated as a podium. The podium is usually designed with a molded base and plinth at the bottom, a central plane surface known as a die, or dado, and a projecting cornice or cap. The majority of Etruscan and Roman temples were raised on podiums, and the entrance steps ascended between wing walls, which were the continuations of the podium at the sides. By extension the term has been applied to other raised platforms, particularly those used by orchestra conductors.

PODOCARPACEAE, a family of conifers consisting of large trees and shrubs, found predominantly in the southern hemisphere. Many are cultivated for ornament and some are important as timber trees in Australia. The seven genera commonly admitted are *Ptherosphaera*, *Microcachrys*, *Saxegothaea*, *Dacrydium*, *Acropyle*, *Podocarpus* and *Phyllocladus*. All occur in the Australasian region except *Saxegothaea*, which is South American; *Podocarpus* and *Dacrydium* also extend their range to that continent. The Podocarpaceae are usually dioecious (having separate male and female plants) and have leaves variously awl-shaped, needlelike or broad, with many parallel veins. In the genus *Phyllocladus*, the foliar leaves are replaced by flattened branchlets (phylloclades) resembling leaves. The staminate, or pollen-bearing, cones are borne in a terminal or axillary position on leafy twigs, each scale bearing two pollen sacs. The ovulate, or seed-bearing, cones may have numerous scales but usually are reduced to one or a few scales with a single ovule and several sterile scales below. At maturity the latter become fleshy and sometimes brightly coloured and surmount the fleshy cone axis. There are two cotyledons (seed leaves) in the mature embryo. See also **CONIFERS**. (R. W. H.)

PODOLIA, an area of western Ukraine south of Volhynia. Extending between the Rivers Dniester and Southern Bug as far as the old Polish frontier of 1772, it is essentially a plateau cut by deep canyons or *yars* of many left-bank tributaries of the Dniester—all flowing from north to south. The name appeared in the 14th century when, after King Casimir III's incorporation of Galicia (1349), Poland began to colonize the steppe lying to the southeast, transforming it gradually into rich arable land. Under Polish rule Podolia was divided between the *województwa* of Kamieniec Podolski and Braclaw. In 1772 the part west of the Zbrucz (Zbruch) River became Austrian, the rest Russian. The Russian part formed the Podolian *gubernya*. After World War I the Zbrucz was the frontier between the restored Poland and the U.S.S.R., but after World War II all Podolia became part of the U.S.S.R. It was then divided between the *oblasti* of Ternopol (Tarnopol), Khmel'nitski, and Vinnitsa. Its population had always a Ukrainian majority. (K. Sm.)

PODOLSK, a town in Moscow *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies 40 km. (25 mi.) due

south of Moscow, on the right bank of the Pakhra River, a tributary of the Moskva. Pop. (1959) 123,816. The village of Podol, created a town in 1781, owed its development to its position on the main highway running south from Moscow. In the 1860s the main railway to the south was built through Podolsk and on to Tula, and industry developed. Sewing machines, steam boilers, ventilating equipment, and cables are manufactured. There are also nonferrous metallurgical and food-processing industries, and cement is made from local limestones. (R. A. F.)

PODOSTEMONACEAE, the river weed family of dicotyledonous plants, a remarkable group living only on rocks in rushing streams. The seeds are shed on the rocks during the dry season, and germinate when the rocks become submerged in the rainy season. The vegetative parts consist mainly of a flattened green thallus, usually derived from adventitious roots. There are more than 40 genera and about 140 species, nearly all tropical; a single representative, *Podostemon ceratophyllum* (river weed), occurs in North America, in shallow streams from Quebec southward to Georgia and Arkansas.

For a treatment of the genera, see A. Engler, "Podostemonaceae" in A. Engler and K. Prantl, *Natürlichen Pflanzenfamilien*, 2nd ed., 18a: 3-68, fig. 1-61 (1930).

POE, EDGAR ALLAN (1809-1849), U.S. poet, critic, and short-story writer, who cultivated the literature of mystery and the macabre, was born Jan. 19, 1809, in Boston, Mass. He was the son of the English-born actress Elizabeth Arnold Poe and David Poe, Jr., an actor from Baltimore. After his mother died in Richmond, Va., in 1811, the boy was taken into the home of the Richmond merchant John Allan, presumably his godfather, and his childless wife. He was taken to Scotland and England (1815-20), where he was given a classical education that was continued in Richmond. For 11 months in 1826 he attended the University of Virginia, where he studied Greek, Latin, French, Spanish, and Italian; but his gambling losses at the university so incensed his guardian that he refused to let him continue, and Poe returned to Richmond to find his sweetheart, Elmira Royster, engaged. Poe went to Boston where he published a pamphlet of youthful Byronic poems, *Tamerlane and Other Poems* (1827), some of which concern Elmira. Poverty forced him to join the army under the name of Edgar A. Perry, but on the death of his foster mother Allan purchased his release from the army, and helped in getting him an appointment to the U.S. Military Academy at West Point, N.Y. Before going, Poe published a new volume at Baltimore, *Al Aaraaf, Tamerlane and Minor Poems* (1829), showing the influence of the local poet E. C. Pinkney and an awakened interest in Milton and Thomas Moore. He successfully sought expulsion from the academy, where he was absent from all drills and classes for a week. He proceeded to New York City and brought out a volume of *Poems* (1831), containing several masterpieces, some showing the influence of Keats, Shelley, and Coleridge. He then returned to Baltimore, where he began to write stories. The rumour that he was again in the army under another name in 1832 seems credible. In 1833 his "Manuscript found in a Bottle" won \$50 from a Baltimore weekly, and by 1835 he was in Richmond as editor of the *Southern Literary Messenger*. There he made a name as a critical reviewer and married his young cousin Virginia Clemm, who was only 13. Poe seems to have been an affectionate husband and son-in-law and wrote the tribute "Sonnet to My Mother" to his aunt, Mrs. Clemm, in 1849.

BY COURTESY OF BROWN UNIVERSITY, PROVIDENCE

EDGAR ALLAN POE, DAGUERRETYPE BY S. W. HARTSHORN DATED 1848

Poe was dismissed from his job in Richmond, apparently for drinking, and went to New York. His drinking was the bane of his life. To talk well in a large company he needed a slight stimulant, but a glass of sherry might start him on a spree; and although he rarely succumbed, he was often seen in public when he did. Medical testimony is that Poe was not a drug addict, but had had a brain lesion. While in New York he published a long prose narrative, *The Narrative of Arthur Gordon Pym* (1838), combining (as so often in his tales) much factual material with the wildest fancies. It is considered one inspiration of Melville's *Moby Dick*. In 1839 he began editing *Burton's Gentleman's Magazine* in Philadelphia. There a contract for a monthly feature stimulated him to write "William Wilson" and "The Fall of the House of Usher"—stories of supernatural horror. The latter contains a study of a neurotic now known to have been an acquaintance of Poe, not Poe himself.

Later in 1839 his *Tales of the Grotesque and Arabesque* appeared (dated 1840). He resigned from *Burton's* about June 1840 but returned in 1841 to edit its successor, *Graham's Magazine*, in which he printed the first detective story, "The Murders in the Rue Morgue." In 1843 his "The Gold Bug" won a prize of \$100 from the *Philadelphia Dollar Newspaper*, which gave him great publicity. In 1844 he returned to New York, wrote the "Balloon Hoax" for the *Sun*, and became subeditor of the *Evening Mirror* under N. P. Willis, thereafter another lifelong friend. In the *Evening Mirror* of Jan. 29, 1845, appeared, from advance sheets of the *American Review*, his most famous poem, "The Raven," which gave him national fame at once. Poe then became editor of the *Broadway Journal*, a short-lived weekly in which he republished most of his short stories, in 1845. During this year the poet Frances Sargent Osgood pursued Poe. Virginia did not object, but "Fanny's" indiscreet writings about her literary love caused great scandal. His *The Raven and Other Poems* and a selection of his *Tales* came out in 1845, and in 1846 Poe moved to a cottage at Fordham (now part of New York City), where he wrote for *Godey's Lady's Book* (May-October 1846) on the "Literati of New York"—gossipy sketches on personalities of the day which led to a libel suit.

His wife, Virginia, died in January 1847. In 1848 Poe went to Providence, R.I., to woo the poet Helen Whitman. There was a brief engagement. Poe had close but platonic entanglements with Annie Richmond and with Sarah Anna Lewis, who helped him financially. He composed poetic tributes to all of them. In 1848 also he published the lecture *Eureka*, a transcendental "explanation" of the universe, which has been hailed as a masterpiece by some critics and as nonsense by others. In 1849 he went south, had a wild spree in Philadelphia but got safely to Richmond, where he again became engaged to Elmira Royster, by then the widowed Mrs. Shelton, and spent a happy summer with only one or two relapses. He enjoyed the companionship of childhood friends and an unromantic friendship with a young poet, Susan Archer Talley.

Poe had some forebodings of death when he left Richmond for Baltimore late in September. There he toasted a lady at her birthday party and began to drink heavily. The indulgence proved fatal, for Poe had a weak heart. He died on Oct. 7, 1849, and was buried in Westminster Presbyterian churchyard in Baltimore.

Appraisal.—Poe's work owes much to the drift of romanticism, of which he was a late heir, toward the occult and satanic. It owes much also to his own feverish dreams, to which he applied a rare faculty of shaping plausible fabrics out of impalpable materials. With an air of objectivity and spontaneity, his productions are closely dependent on his own idiosyncrasy and an elaborate technique. His keen and sound judgment as appraiser of contemporary literature, his idealism and musical gift as a poet, his weirdness and dramatic power as a storyteller, considerably appreciated in his lifetime, secured him a prominent place among universally known men of letters.

The outstanding fact in Poe's character is a strange duality. The wide divergence of contemporary judgments on the man seems to point to the coexistence in him of two persons. With those he loved he was gentle and devoted. Others, who were the butt of his sharp criticism, found him irritable and self-centred and went

so far as to accuse him of lack of principle. Was it, in the latter case, a double of the man rising from harrowing nightmares, or from the haggard inner vision of dark crimes, or from appalling graveyard fantasies that loomed in Poe's unstable being?

Much of Poe's best work is concerned with terror and sadness, but in ordinary circumstances the poet was a pleasant companion. He talked brilliantly, chiefly of literature, and read his own poetry and that of others in a voice of surpassing beauty. He admired Shakespeare and Alexander Pope. He had a sense of humour, apologizing to a visitor for not keeping a pet raven. If the mind of Poe is considered, the duality is still more striking. On one side, he was an idealist and a visionary. His yearning for the ideal was both of the heart and of the imagination. His sensitiveness to the beauty and sweetness of women inspired his most touching lyrics ("To Helen," "Annabel Lee," "Eulalie," "To One in Paradise") and the full-toned prose hymns to beauty and love in "Ligeia" and "Eleonora." In "Israfel" his imagination carried him away from the material world into a dreamland. This Pythian mood was especially characteristic of the later years of his life.

More generally, in such verses as "Valley of Unrest," "Lenore," "The Raven," "For Annie," and "Ulalume" and in his prose tales, his familiar mode of evasion from the universe of common experience was through eerie thoughts, impulses, or fears. From these materials he drew the startling effects of his tales of death ("The Fall of the House of Usher," "The Masque of the Red Death," "Valdemar," "Premature Burial," "Oval Portrait," "Shadow"), his tales of wickedness and crime ("Berenice," "Black Cat," "William Wilson," "Imp of the Perverse," "Cask of Amontillado," "Tell-Tale Heart"), his tales of survival after dissolution ("Ligeia," "Morella," "Metzengerstein"), and his tales of fatality ("Assignment," "Man of the Crowd"). Even when he does not hurl his characters into the clutch of mysterious forces or onto the untrodden paths of the beyond, he uses the anguish of imminent death as the means of causing the nerves to quiver ("The Pit and the Pendulum"), and his grotesque inventions deal with corpses and decay in an uncanny play with the aftermath of death.

On the other side, Poe is conspicuous for a close observation of minute details, as in the long narratives and in many of the descriptions that introduce the tales or constitute their settings. Closely connected with this is his power of ratiocination. He prided himself on his logic and carefully handled this real accomplishment so as to impress the public with his possessing still more of it than he had; hence the would-be feats of thought reading, problem unraveling, and cryptography which he attributed to his Legrand and Dupin. This suggested to him the analytical tales, which introduced into literature the detective story, and his tales of pseudoscience.

The same duality is evinced in his art. He was capable of writing angelic or weird poetry, with a supreme sense of rhythm and word appeal, or prose of sumptuous beauty and suggestiveness, with the apparent abandon of compelling inspiration; yet he would write down a problem of morbid psychology or the outlines of an unrelenting plot in a hard and dry style. In Poe's masterpieces the double contents of his temper, of his mind, and of his art are fused into a oneness of tone, structure, and movement, the more effective, perhaps, as it is compounded of various elements that give depth and intensity to the total sheen or dismal glow.

As a critic Poe laid great stress upon correctness of language, metre, and structure. He formulated rules for the short story, in which he sought for the unities of time, place, and action, and added that of mood or effect. He regarded didacticism as not necessary, and so was a leading advocate of art for art's sake. He was not extreme in these views, however. He praised longer works and sometimes thought allegories and morals admirable if not crudely presented. Poe admired originality, often in work very different from his own, and was sometimes an unexpectedly generous critic of decidedly minor writers.

Poe's genius was recognized abroad. No one did more to persuade the world and, in the long run, the United States, of Poe's greatness than Baudelaire and Mallarmé.

BIBLIOGRAPHY.—The best biographies of Poe are by G. E. Woodberry, *Life of Edgar Allan Poe*, 2 vol. (1909); A. H. Quinn, *Edgar Allan Poe* (1941); and V. Buranelli, *Edgar Allan Poe* (1961). The first biographer, R. W. Griswold (1850), blackened Poe's character; the most popular, Hervey Allen's *Israfel*, 2 vol. (1926), is partly fictionalized. Mary E. Phillips, *Edgar Allan Poe, the Man*, 2 vol. (1926), uncritically collects much information. Most noteworthy perhaps among the many other books on Poe are Arthur Ransome, *Edgar Allan Poe* (1910); and N. B. Fagin, *Histrionic Mr. Poe* (1949).

(C. C.; T. O. M.)

POERIO, ALESSANDRO (1802–1848) and **CARLO** (1803–1867), brothers distinguished for their services to liberalism in the Italian Risorgimento, were the sons of Baron Giuseppe Poerio, a Neapolitan lawyer well known for his own liberal sympathies.

ALESSANDRO was born in Naples on Aug. 27, 1802. Having been taken into exile by his father on the Bourbon restoration in 1815 (see NAPLES, KINGDOM OF), he returned to Naples in 1818 and was able in 1821 to enlist as a volunteer in the army; he fought against the Austrians at Rieti. After this defeat he again went with his family into exile and traveled in Germany, where he became the friend of Goethe. He began to write poetry, which was highly esteemed though its bulk was small because of his perfectionism. His writings had great inspirational importance during the Risorgimento. When the family was again allowed to come back to Naples (1833), Alessandro came with them. In 1848 he again volunteered to fight the Austrians (see ITALIAN INDEPENDENCE, WARS OF) and died in Venice on Nov. 3 of wounds received at Mestre.

CARLO was born in Naples on Oct. 13, 1803. He shared in the exiles of his family, and when he returned to Naples in 1833 he was an object of constant suspicion, though he was careful to play no part in politics. He was arrested in 1837, 1844, and 1847. In the revolution of 1848 he helped to formulate the demands of the constitutionalists and then became at first director of police and afterward minister of education in the Liberal government. After his resignation in May 1848 he led the constitutional opposition. He was again arrested in July 1849, but was not tried until February 1851, when he was sentenced with his fellow Liberals to 24 years in irons. The illegality of the trials, the atrocious sentences, and the sufferings of the prisoners horrified the visiting English politician W. E. Gladstone (q.v.), who denounced the conditions of the Neapolitan prisons in his two *Letters to Lord Aberdeen* (July 1851) and so made Poerio's case notorious throughout Europe. Poerio was not released until January 1859 and then made his way to London. After the outbreak of war between Sardinia-Piedmont and Austria he went to Turin (Torino). A deputy in the Parliament of the new Kingdom of Italy (1861), he later refused a governmental portfolio. He died in Florence on April 28, 1867, of a complaint contracted during his imprisonment.

POETIC IMAGERY. The term "poetic imagery" may be considered as including all possible methods of making the kind of statement by which one thing is perceived as resembling, or in terms of, another. These may be compressed into three broad classifications: simile, metaphor, and symbol (see also FIGURES OF SPEECH). The simile, introduced by "like" or "as," indicates a specific and unequivocal correspondence; its variant, the so-called Homeric or epic simile, is merely a passage of greater or less length introduced by "as" or "like" and bound into the main narrative by "so" or some equivalent. Metaphor also involves such a correspondence, but here the statement is direct, without the introductory "like" or "as"; the reader is invited to infer the poet's intention by an effort of his own imagination and to set up, as it were, a fusion between the object and the image. The symbol carries the method a stage further, calling for a more intense and subtle imagination and often employing a system of correspondences of great complexity.

From classical times the making of images has been recognized as a central poetic activity. Aristotle pointed out that the capacity for making metaphors was the mark of the superior poet, Shelley

that the language of poetry was "vitally metaphorical." Longinus devoted 17 chapters of his treatise *On the Sublime* to a consideration of the "figures" of speech. The methods of using them were elaborated and analyzed by the classical rhetoricians (see RHETORIC), and passed into English criticism with the Renaissance. Such analysis belongs to a method of poetic composition that is only of academic interest to modern critics and writers; and its terms have only a limited critical application. Here an attempt must be made to return to first principles.

The object or experience that the poet is contemplating is perceived by him in a relationship to some second object or event, person or thing, to which he directs attention. By this act he may be thought to transfer from this image certain qualities which are then perceived as attributes of the original object; the poet's intention being to decorate, illuminate, emphasize, or renew by such transferences the original character of that which he contemplates. The making or finding of the image is an activity by which the poet is inviting the reader to establish certain relationships, which in turn involve judgments of value. Image and symbol are, in one sense, the outcome of the poet's impulse to perceive unity in diversity, or to draw together a number of apparently unrelated experiences, or to communicate through their submerged or penumbral statements meanings that are beyond the resources of direct language. Images also differ in the depth or profundity or complexity of the meanings implied, as well as in their purpose and origin; and they may derive additional force and vitality from their contextual relation to other images in the poem, from the tradition in which the poet is working, and from the meanings which he may have established in his other work. All may be modified by the usual methods of poetic technique; they may become charged with special significance or interact one upon another.

In making these comparisons the "gap" between the object and the image will vary; if this gap is small, so that the least possible imaginative effort is needed to bridge it, the image may soon become "dead" or ineffectual, as with much "household" or proverbial imagery; for instance, "black as pitch," "sharp as a needle," "dumb as an ox." If the gap is too wide, the imagination may refuse to bridge it, and the comparison fails in its purpose. Good metaphysical imagery, at its best, involves a gap that is wide enough to startle the reader into attention, yet not so wide as to frustrate the imaginative effort. Bad metaphysical imagery, on the other hand, may become ineffective because the comparison is too remote, fantastic, or unduly cerebral in its origins; hence Dr. Johnson's famous stricture on Abraham Cowley: "The most heterogeneous ideas are yoked by violence together." Both good and bad categories are included in the term "conceit," meaning any far-fetched comparison; that it is not necessarily used with pejorative intention can be seen from Dr. Johnson's comment on the metaphysical poets: "If their conceits were far-fetched, they were often worth the carriage."

Examples of unsuccessful metaphysical imagery are to be found in Joseph Addison's "Essay on True and False Wit" (*Spectator*, No. 62):

The passion of love in its nature has been thought to resemble fire; for which reason the words fire and flame are made use of to signify love. The witty poets therefore have taken an advantage from the doubtful meaning of the word fire, to make an infinite number of witticisms. Cowley, observing the cold regard of his mistress's eyes, and at the same time their power of producing love in him, considers them as burning-glasses made of ice; and finding himself able to live in the greatest extremes of love, concludes the Torrid Zone to be habitable. When his mistress has read his letter written in juice of lemon by holding it by the fire, he desires her to read it over a second time by love's flames. . . . Sometimes he is drowned in tears, and burnt in love, like a ship set on fire in the middle of the sea.

The foregoing aspects of poetic imagery may be illustrated by quotations of varying degrees of complexity. The simplest type of simile occurs in the lines:

Set me as a seal upon your heart, as a seal upon your arm;
for love is strong as death, jealousy is cruel as the grave.

(Song of Solomon, 8:6)

In the following simile from Bishop Henry King's *Exequy* on the

death of his young wife, we are aware of a greater depth:

But hark! My pulse, like a soft drum,
Beats my approach, tells *Thee* I come . . .

(Bishop Henry King, *The Exequy*, c. 1624)

since the "soft drum," in conjunction with the "approach," suggests both the advance party of the army nearing the billets for the night and the slow, inexorable, and welcome progress to death and reunion. When John Donne uses the metaphor of "spider love" in "Twickenham Garden":

But O selfe-traytor, I do bring
The *spider love*, which transubstantiates all,
And can convert Manna to gall . . .

we can distinguish several differing overtones of meaning: the web or net (and perhaps a hair-image behind that), the destruction of male by female, voraciousness, subtlety, patience, the Elizabethan lore of the poisonous spider, the peculiar force of the theological "transubstantiates" in conjunction with "manna" and "gall," which themselves have a double biblical reference. But there is a wholly different usage or invention of the metaphor in the following passage from "Solomon and the Witch" by W. B. Yeats, in which some of the connotations of "spider" mentioned above are joined by the new idea of the spider's "eye" with its host of magnifying lenses:

For though love has a spider's eye
To find out some appropriate pain—
Aye, though all passion's in the glance—
For every nerve, and tests the lover
With cruelties of Choice and Chance . . .

(Reprinted with permission of the publisher from
The Collected Poems of W. B. Yeats. Copyright

by Bertha Georgie Yeats.)

Many metaphors are used for the human body, such as "the vessel of clay," "the soul's dark cottage," the dungeon in which the soul is imprisoned. It may also be regarded as something "woven" or "knotted"; thus Donne's

As our blood labours to beget
Spirits, as like souls as it can,
Because such fingers need to knot
This *subtle knot*, which makes us man . . .
(*The Ecstasy*)

or Cleopatra's

Come, thou mortal wretch
With thy sharp teeth this *knot intricate*
Of life at once untie.
(*Antony and Cleopatra*, Act V, scene 2, ll. 306-308)

Sometimes we have a system of technical references which (depending on the degree to which we are prepared to consider and accept such technicalities) may succeed as an image or fail as a conceit; as in Shakespeare's *King John*:

The tackle of my heart is crack'd and burn'd
And all the shrouds wherewith my life should sail
Are turned to one thread, one little hair . . .
(Act V, scene 7, ll. 52-54)

where the normal image of the voyage of life is "compounded" with the details of seamanship, Elizabethan physiology (the "heartstrings"), and perhaps the familiar image of the "thin-spun thread" of life.

The metaphor shades into the symbol; and if the same image is used consistently throughout a poem it may be appropriate to call it a symbol. It may be thought of also in terms of correspondences; a person, event, object, or myth is perceived by the poet to embody a number of significances, to which he directs the reader's attention. Religious symbols offer the most familiar examples: e.g., cross, cup, lamb, rose, candle. Birds, beasts and reptiles, the heavenly bodies, sea and desert, forest and river, music and dance, artifacts of many kinds are symbols often used in poetry. If we contrast these symbols with metaphor, we may recognize correspondences involving a far more complicated series of meanings. The poet will justify himself by asserting that these meanings can be communicated in this manner and in no other; they are not susceptible to analysis. In this lies a danger; for in the interpretation of many symbols, and of some metaphors, there

is an element which is in part subjective. This gives rise to the accusation of impreciseness often leveled against certain types of symbolism, as well as to variations in exegetical findings among critics (see TEXTUAL CRITICISM).

The field of symbolism is one of immense complexity, and here again illustrations must be arbitrary. The tower appears traditionally in many forms; as man's aspiration toward heaven, as a defense or refuge, as an expression of his pride or defiance. We may think of Milton's poet-scholar in the "high lonely tower" of "Il Penseroso" or of Shelley's *Prince Athanasia*. The tower may have many ancillary aspects: an upper room lit by night (for the dissemination of wisdom and learning); its battlements may be defensible or in decay; the poet may emphasize aspects of its winding stair. To quote Yeats:

I declare this tower is my symbol; I declare
This winding, gyring, spiring treadmill of a stair is my
ancestral stair;
That Goldsmith and the Dean, Berkeley and Burke have
travelled there.

("Blood and the Moon," II. Reprinted with permission of the publisher from *The Collected Poems of W. B. Yeats*. Copyright 1933 by The Macmillan Company. Renewed 1961 by Bertha Georgie Yeats.)

Blake offers symbols of profound significance in apparent simplicity; as in "The Sick Rose," to which his own illustration provides subsidiary but complementary symbols in the caterpillar and the thorns on which humanity is as it were crucified:

O Rose thou art sick.
The invisible worm,
That flies in the night
In the howling storm:
Has found out thy bed
Of crimson joy:
And his dark secret love
Does thy life destroy.

It is possible to isolate some of these symbols, in their traditional aspects, and so to indicate some points of departure toward the apprehension of their meaning. The rose is traditionally the symbol of womanhood, the worm (or serpent or dragon) the male principle; the storm suggests any conflict, physical or mental. But (as always with the symbol) its peculiar qualities and significance rest in the totality of the statement of which the symbol is a component part.

For a last example of a different kind of complexity, in which the symbol is fused with mythology, we may consider the swan. All birds are likely (for obvious reasons) to become associated with the human soul or spirit. The swan has many associated qualities: whiteness, purity, strength, fidelity in love, its mysterious music of wingbeat or of cry, its song at death; therefore the human associations become more intense. These qualities are stabilized in myth and folklore; they pass through many imaginations and emerge, for instance, in Yeats' poem "Leda and the Swan" in which the symbol has become enriched not only by tradition but also by contextual images and associations in the rest of the poet's work.

It should be stressed again that the correspondences that appear in the symbol do not make use of the arbitrary or precise equivalents such as are found in allegorical or emblematic writing (see ALLEGORY; EMELEM BOOKS). The symbol is independent in usage and meaning in each work in which it exists (however much it may be rooted in tradition); it appears to renew itself and to radiate fresh significance, when it is handled afresh by genius, in each new context in which it manifests itself.

Certain metaphors and symbols, because they are constant throughout world literature, are often called archetypal. Their continued vitality suggests that they correspond to profound and perennial aspects of the human situation. Among them are many myths, such as the descent into the underworld, the slaying of the dragon, the rescue from the enchanted castle; flowers of all kinds, often symbolizing womanhood or its virtues; tower, tree, cave; the sea voyage; fountain or well; and birds, beasts, and reptiles of many kinds. The investigation of them has brought both anthropology and psychology to the service of literary criticism.

POET LAUREATE. In England, since the 17th century, the title "poet laureate" has referred to a salaried member of the royal household, and with the early civic and university degrees of baccalaureate it has little to do, except as an extension of the tradition. Its uniqueness lies in its continuity, for in no other time or country has the death of a pensioned poet called for the immediate appointment of a successor, with the same rights, duties, and emolument. The office began with a pension granted to Ben Jonson by James I in 1616, and confirmed and increased by Charles I in 1630 (when the famous annual "butt of canary wine" was added, to be discontinued at the request of Henry James Pye—made laureate in 1790—who preferred the equivalent in money). Jonson's pension specifically recognized his services to the crown as a poet, and envisaged their continuance; but it was 16 months after Jonson's death in 1637 before a similar pension for similar services was granted to Sir William Davenant. It was with Dryden's appointment in 1668 within a week of Davenant's death that the laureateship was recognized as an established royal office to be filled automatically when vacant. At the revolution of 1688 Dryden was dismissed for refusing the oath of allegiance and this gave the appointment a political flavour which it retained for more than 200 years, for so late as 1896 Alfred Austin was appointed less for his poetry than for his conservatism. Dryden's successor, Thomas Shadwell, inaugurated the custom of the new year and birthday odes which hardened into a tradition between 1690 and about 1820, becoming the principal mark of the office. The odes were set to music and performed in the sovereign's presence, providing a long series of the worst poems ever written. On his appointment in 1813 Robert Southey sought unsuccessfully to end this custom, but although it was allowed tacitly to lapse about 1820 it was only finally abolished by Queen Victoria. Victoria's appointment of Wordsworth in 1843 recognized that the laureateship had become the reward for eminence in poetry rather than the vehicle for providing fulsome verses, and the office since then has carried no specified duties; the laureates from Tennyson onward have written poems for royal and national occasions as the spirit has moved them.

The list of poets who enjoyed the official title of poet laureate is (with the date of their appointment) as follows: Dryden (1668); Shadwell (1688); Nabum Tate (1692); Nicholas Rowe (1715); Laurence Eusden (1718); Colley Cibber (1730); William Whitehead (1757); Thomas Warton (1785); Henry James Pye (1790); Southey (1813); Wordsworth (1843); Tennyson (1850); Alfred Austin (1896); Robert Bridges (1913); John Masefield (1930).

See E. K. Broadus, *The Laureateship* (1921); Kenneth Hopkins, *The Poets Laureate* (1954). (K. Ho.)

POETRY. It seems probable that poetry originated in the magical spells, the ritualistic incantations, and the highly rhythmic and formalized storytelling of early tribal society. It made use of sympathetic magic in its listing of desired events in order to cause them to occur. It appears to have developed a sophisticated use of symbols and of various "levels" of diction quite early in its history, if evidence from the current oral literature of primitive tribal societies in different parts of the world is to be relied on. While being, in some forms, a "sacred" art or "mystery" associated with the practice of fertility and purification rituals, and with ideas of spiritual possession, it seems also always to have had recreational

aspects. Even in its periods of greatest religious and magical significance, it seems to have been regarded as a game to be played with words, an entertainment, pastime, and mode of personal emotional release, as well as a religio-political ceremonial.

As poetry became detached from its religio-political functions, it became free to develop as entertainment, while continuing to include narrative, ritualistic, incantatory, and pseudoreligious elements. The figure of the poet, who had been revered as either priest or divine lunatic, lost its stature; though a poet might still be regarded with awe and given considerable status as a consequence of his work, his importance was seen to lie more in the value of his products than in his possession of spiritual powers. Moreover, poetry became a matter for public discussion and evaluation rather than a "mystery" of which only the elect might speak.

Several kinds of poetry have developed as a consequence of the poet's attempts to regain his lost status. Thus, satirical poetry can be regarded as a product of the poet's attempt to regain his position as an authoritative (because possessed or inspired) regulator of manners, morals, and forms; it is not merely the consequence of particular social conditions at a particular time. The epic, which, as an oral form, came into being to satisfy the human desire to recall past glories and establish genealogies at the same time as being entertained, owes its existence in written literature to the poet's attempt to set himself up as historian, genealogist, and mythmaker to a whole culture. It can even be argued that the poet's ventures into drama, particularly religious drama, are connected to this drive for lost authority, and many other kinds and attributes of poetry may also be related to the attempt of the poet in a literate and sophisticated society to regain the position and power he had in an illiterate and primitive one.

Poetry is not, however, simply residual. Although its relationship to society has altered it has not become insignificant. Up to the end of the 18th century, for example, poetry was still capable of having considerable effect upon public events; since then little poetry has had much social influence, though W. B. Yeats once wondered whether his words had aroused a destructive amount of national zeal in his fellow-Irishmen. In the 20th century poetry has become of importance to the solitary reader rather than to the political establishment, though in totalitarian states the poet's work is viewed with more respect and less tenderness. This "private" aspect of poetry is reflected in the numerous attempts at a definition made since the 17th century. Only a few treat poetry as a social phenomenon; the majority describe it either in terms of its relationship to the emotional perceptions of its makers or, more pretentiously, in terms of its profound insights into eternal truths. George Eliot neatly combined these attitudes in her statement (in her novel *Middlemarch*, 1872) that "To be a poet is to have a soul . . . in which knowledge passes instantaneously into feeling, and feeling flashes back as a new organ of knowledge." This, with its leaning toward the idea of a "fourth way of knowing" as described by the English Platonists, is a typically 19th-century view. Moreover, it elevates the poet to the status of a seer, and thus echoes the attitudes to poetry of both Wordsworth and Coleridge (*qq.v.*). Another 19th-century view is that of Herbert Spencer, who defined poetry (in his essay "On the Origin and Function of Music") as "a form of speech for the better expression of emotional ideas." Louis MacNeice, in the 20th century, has described it as "a precision instrument for recording a man's reactions to life." This statement implies recognition of the psychological accuracy of poetry's modes of procedure, and suggests that the various devices of poetry correspond to certain deep-seated needs and instinctive behaviour patterns possessed by all men. The word "precision" is, indeed, a pointer to the modern emphasis, in poetic theory, on the examination of linguistic procedures and their relationship to the structure of society and the psychology of the individual.

This approach to poetry, which is, obviously, yet another attempt to give it a publicly acceptable "image," may well have its origin in Matthew Arnold's view that "Poetry is at bottom a criticism of life," to which T. S. Eliot retorts "Arnold might just as well have said that Christian worship is at bottom a criticism of the Trinity." In the confrontation between Arnold and Eliot can be seen clearly the main division among those critics who have at-

tempted to define poetry in terms of its purpose. The one view sees poetry as a mode of discovering or expressing universal truth, and the other regards it as a mode of exploring and expressing the individual's reactions to experience in such a way that, while so-called general truths may emerge, they are not inextricably an element of poetry itself. This second view is trenchantly expressed by Christopher Fry, in his statement that "Poetry is the language in which man explores his own amazement." This is still, however, a definition based upon a notion of purpose, and can easily be countered by listing other purposes which appear to have animated poetry from time to time.

Another kind of definition attempts an analysis of the effect of poetry upon the reader; by describing the sensations which invariably accompany a reader's recognition of "poetry" the critic hopes to provide a formula to describe the stimulus which arouses those sensations. One of the most satisfactory formulations is that of Clive Sansom, who includes in his definition a reference to the physical properties of poetry. He states that "Poetry is a rhythmical form of words which expresses an imaginative-emotional-intellectual experience of the writer's, and expresses it in such a way that it creates a similar experience in the mind of his reader or listener." This, if the word rhythmical is not taken as referring only to metrical writing, probably comes fairly close to the target. It does, however, suggest that the reader's experience must necessarily be similar to that of the writer. This seems unlikely. The writer may have created his poem without conscious thought, or almost by accident, or he may have created it by taking enormous pains and as a consequence of largely technical concern. Those definitions of poetry which presume any close similarity between the attitude of the maker while making and that of the reader while reading are based upon an altogether too naïve view of the nature of the creative process. Nevertheless, it is likely that no reader will regard a piece of writing as a poem unless he derives from it an "imaginative-emotional-intellectual" experience which includes a recognition of the verbal dexterity of the writer and a satisfying conviction of the completeness of the experience. The poem must satisfy the reader's need to arrange emotional experience in patterns for the purpose of better understanding and better manipulation, as well as provide him with a more than usual intensity of perception.

This intensity of perception experienced by the reader has often been related to that experienced by the poet while writing. Although many poems are made with an almost complete awareness of the techniques that are being used, it is also true that almost no poem is completed without the poet's being aware of subconscious promptings. A part of every poem, indeed, and all of some, is made by the poet in a condition of "trance," or, as Brewster Ghiselin has expressed it, "with a consciousness partially unfocused." This has been emphasized by many critics: Goethe referred to "That undisturbed, direct manner of working, almost like a sleepwalker," and C. Day-Lewis, concentrating upon another aspect, insisted that "it cannot be said too often that a poet does not fully know what is the poem he is writing until he has written it." This, and other aspects of the creative process are being investigated by psychologists, but no consensus has yet been reached. It seems probable, however, that the "trance" is a manoeuvre, intuitively organized, on the part of the poet, to arrange that his associative powers be given freedom to work at full strength without overmuch restraint by the fully conscious intelligence, and to arrange also that certain complex movements be made intuitively because they cannot be achieved consciously. Just as a juggler, once trained, can perform, without thought, feats which he could not possibly manage were he to calculate every trajectory, so the poet, engaged in manipulating rhythm, cadence, syntax, diction, connotative richnesses, and symbolic profundities, is obliged to operate without taking too much thought. It is, however, interesting to note that the "deepest" poetic trances are usually experienced in a poet's youth or by comparatively unpractised poets; the "professional" poet finds, as time goes on, that he can rely more and more upon his conscious powers.

When this is taken into account, it becomes clear that those definitions of poetry which are dependent upon a near-mystical

view of the nature of "inspiration" are as ill-based as those which refer to the poet's "intention," or to the reader's sharing the poet's experience. It is easier, indeed, to approach the definition of poetry by analyzing its appearance than either its purpose or its origins. This approach leads to varying conclusions, for at different times and in different societies poetry has been shaped differently and differently regarded. In the history of English and American poetry, for instance, there have been many fashions, each one of which has given rise to different ideas of the poetic task, and established, implicitly or explicitly, different criteria for the judging of poetic success. Thus the early 18th-century emphasis upon "correctness" produced a view of poetry, and a kind of poetry, very different from that influenced by the Coleridgean emphasis upon "organic form" in the 19th century. In the 20th century each of a number of "movements" has suggested different approaches, and has emphasized one aspect of poetry at the expense of others. Thus, Imagism, Symbolism, and Surrealism have all given rise to different definitions of, and practices in, poetry.

Nevertheless, though it is difficult to define poetry, it is comparatively easy to describe its various manners and modes, though one must be careful not to allow pedantry to become a straitjacket, and even more careful to point out that the classification of phenomena is not the establishment of laws.

Poetry can be said to make use of various media, the most usual being verse, though some poems have been deliberately composed in prose, and some "prose" can be described as poetry. Verse may be defined as an obviously rhythmical use of language, manipulating accent, stress, and cadence in such a way as to create recurrent patterns of emphasis. Free verse (*q.v.*), or *vers libre*, though it often makes use of the repetition of syntactical forms and of words and phrases, is not governed by any other rule. Metrical verse, on the other hand, has many very restrictive manifestations, although in the 20th century it has become usual to mingle metres and to treat so-called "laws" with easy familiarity, if not with downright contempt. The main English metres are the iambic, trochaic, anapaestic, and dactylic, the last-named usually appearing in a catalectic form. (See also VERSE; METRE, and for the metres of classical poetry, PROSODY, CLASSICAL.)

Poetry has its modes as well as its media. Some of these have their origin in the work of particular groups of people working at a particular period; thus, for instance, the terms Petrarchan, Cavalier, Metaphysical, Augustan, Romantic, Symbolist, Imagist, and Surrealist, used to describe particular poetic modes, are connected with particular episodes or periods in the history of poetry. Nevertheless, these terms do describe modes of operation, basic attitudes, and varied views of the poet's role, and, on this account, are of value in describing the poetry of periods other than that in which they originated.

Poetry has its genres also, both major and minor. The major genres are satire (*q.v.*), epic (see EPIC POETRY), lyric, and drama (*q.v.*). Satire includes didactic or critical poetry of a humorous or invective kind. The epic genre includes any long poem, or fragment of a presumed long poem, which deals with heroic themes of historical importance in high-sounding language. The English view of the epic derives largely from Homer and Virgil, although it does not differ in essentials from the view held in other countries with different traditions. The lyric genre includes any poetry intended to be sung, or clearly derived from a song tradition; thus both the ode and the epigram (*q.v.*) belong to the lyric genre, and a short satiric poem may belong both to the lyric and satiric genres. Drama as a poetic genre includes masque (*q.v.*) and litany as well as poetic drama, and such forms as the pastoral eclogue (see PASTORAL) and the dramatic monologue (*q.v.*) should properly be considered as drama.

The minor poetic genres are numerous. The most important are parody, elegy, hymn, and ballad (*q.v.*). These are to be regarded as genres rather than as forms because in each much variety of structure is possible. All but the parody are subspecies of the lyric. Parody is, of course, satiric, and may be also lyric, epic, or dramatic.

Within these general categories poetry also includes various "established" forms. Among the forms in use in English and Amer-

ican literature are some imitated from forms first established in other linguistic cultures: e.g., the sonnet, villanelle, ballade, rondeau, chant royal, canzone, sestina, and triolet (*q.v.*) which are all of European origin; and, from non-European literatures the Malayan pantoun (pantun, *q.v.*), and the Japanese *haiku* and *tanka* (see JAPANESE LITERATURE). Forms used usually for jocular purposes are the limerick and the clerihew (*q.v.*).

In attempting to define poetry it is not necessary to explore the minutiae of verse, and only necessary to mention that certain stanza forms have become as established as those forms mentioned above. The most important of these are the Spenserian and neo-Spenserian stanza, and the Burns stanza. In addition to these there are forms which, having no set rules, do follow certain principles established by their previous usage in other languages. Notable among such imitated forms are the Horatian and the Pindaric ode (see ODE; PINDARICS).

Verse is, however, only one of the media of poetry, and much verse is not poetry at all. This has been recognized, but the recognition has never led to a satisfactory distinction between poetic and nonpoetic verse, or between poetic and nonpoetic prose. It seems finally that once those criteria provided by past poetic fashions, and habitual beliefs about what is "usual" in poetry, are found useless, we are thrown back upon simple assertion concerning the nature of the reader's experience. If any one reader says of a piece of writing "this is poetry" we are obliged to admit that it may be so for him, though it need not be so for us. Thus the concept "poetry" is, ultimately, many-faceted, manipulatable, and definable only in terms of established practices which it is the chief endeavour of every poet to oppose, alter, and transform. Moreover, it is also clear that, from another point of view, and in the last resort, poetry is a quality, not of the thing written, but of the reader.

POGGIO (GIAN FRANCESCO POGGIO BRACCIOLINI) (1380-1459), Italian humanist, foremost among scholars of the early Renaissance as a rediscoverer of classical Latin manuscripts, was born at Terranuova in Valdarno on Feb. 11, 1380. From 1399 to 1400 he studied in Florence to be a notary, and was befriended by Coluccio Salutati, who also used him as a copyist of manuscripts. Poggio's invention of the humanist script, based on the Caroline minuscule, is attributed to these years. (See PALEOGRAPHY.) In 1403 he moved to Rome, where he became a secretary to Boniface IX. The rediscovery of the treasures of the ancient world, with which his name will always be associated, began soon after his attendance on the schismatic pope John XXIII at the Council of Constance in 1414. During a visit to Cluny in the spring of 1415 he brought to light two unknown orations of Cicero. At Saint-Gall in June-July 1416, in the company of his friends and fellow scholars, Cencio de' Rustici and Bartolomeo da Montepulciano, he found the first complete text of Quintilian's *Institutio oratoria*, the first three books and part of book four of Valerius Flaccus' *Argonautica*, and the commentaries of Asconius Pedianus on some of Cicero's orations. Various expeditions in 1417, alone or with Bartolomeo da Montepulciano, to Fulda, Saint-Gall, and other monasteries, produced P. Festus, *De significatione verborum*; Lucretius, *De rerum natura*; Manilius, *Astronomicum*; Silius Itali-

cus, *De bello punico*; Ammianus Marcellinus, *Res Gestae*; Apicius on cooking; and other lesser works. He also found at Langres in 1417 Cicero's oration *pro Caecina*, and perhaps at Cologne seven other orations of Cicero. It is not known where and when he discovered the *Silvae* of Statius. Poggio made copies of the newfound works, in his elegant script, several of which still survive.

On the election of Martin V in 1417, Poggio failed to regain his post at the Curia, and decided to accept the invitation of Henry Beaufort, bishop of Winchester, to enter his service. He spent four not very happy years (1418-23) in England, where his hopes of continuing his discoveries were disappointed by English libraries; and this lack of facilities combined with the scholasticism prevalent in England led him to direct his studies to the early Fathers. At this time he also took minor orders, which enabled him to enjoy certain benefices, though he was never ordained priest.

He returned to Rome early in 1423 and was reappointed curial secretary soon after. Taking up his researches with renewed vigour, seeking in person, inquiring by letter, interrogating foreign visitors to Rome, he made further discoveries, including Frontinus' *De aquaeductibus* and Firmicus Maternus' *Matheseos libri*, the latter found at Monte Cassino in 1429. He also sought Greek manuscripts from abroad and translated into Latin Xenophon's *Cyropaedia*, the histories of Diodorus Siculus, and Lucian's *Ass*. His classical interests extended to the study of ancient buildings and the collections of inscriptions (of which two autograph copies survive) and of works of sculpture, with which he adorned the garden of his villa near Florence. The attraction of his native Tuscany, and the invitation from Florence to succeed Carlo Aretino as chancellor, finally drew him from his long career in Rome (1453). His last years were spent in exercising this office and in writing his history of Florence, which he completed not long before his death on Oct. 30, 1459.

Besides his talent for rediscovery of ancient manuscripts, Poggio was gifted with a lively eloquence and a capacity for artistic representation of character and conversation that distinguish his moral dialogues from the numerous contemporary works of a similar kind. The most important of these are *De avaritia* (1428-29), *De varietate fortunae* (1431-48), *De nobilitate* (1440), and *Historia tripartita disceptativa convivialis* (1450). A vein of sadness and pessimism runs through some of these works (especially that concerning Fortune), and appears strongly in his *De miseria humanae conditionis* (1455). Though professedly an ardent Ciceronian, Poggio was hardly inhibited in practice by preoccupations of style, and commanded a wide, racy, and sometimes obscene Latin, frequently used with mordant wit against critics and enemies. His *Facetiae* (1438-52), a collection of humorous, often indecent, tales, contain vigorous satire on monks and clerics and on rival scholars such as Francesco Filelfo, with whom, as also with Lorenzo Valla (*q.v.*), Poggio engaged in the most notorious and vituperative polemics of a polemical age. This same spirit of violent invective and satire informs his dialogue *Contra hypocritas* (1447-48), directed against ecclesiastics of all kinds and against certain individuals in particular. Poggio's ability to handle Latin as a live idiom is best shown in his copious correspondence, which for its form as much as for its content stands out among the *epistolari* of the humanists. His *Historia florentina* in eight books is largely a narrative of the wars of Florence from 1350 to 1445. Lack of comment on internal affairs and of critical awareness of cause and effect make it a work of limited historical value.

BIBLIOGRAPHY.—Some of the dialogues and the *Facetiae* were printed in the 15th century; there were collected editions in 1511 and 1513, and in 1538; and editions of *Historia florentina*, in *Rerum Italicarum Scriptores*, vol. XX (1731), and of *Epistolario*, by T. Tonelli, 3 vol. (1832-61). There are modern editions of *Contra hypocritas*, by G. Vallesse, with Italian trans. (1946); and of *De avaritia* in E. Garin, *Prosatori latini del '400* (1952).

(C. G.)

POGONOPHORA, a remarkable phylum of wormlike, sedentary marine animals that lack a digestive tract, possess a body cavity (coelom), and bear one to many fringed tentacles at the anterior end. Commonly called beard worms because of their tentacles, pogonophores are long and slender, ranging in length from 4 to 12 in., with a diameter up to $\frac{1}{16}$ in. in larger species. Pogonophores are widely distributed in seas off continents and large islands.

Representatives of this group, assigned to the genus *Siboglinum* and described by M. Caullery in 1914, were dredged by the Dutch ship "Siboga" off Malaya at the turn of the century. The phylum was established in 1955 by the Soviet zoologist A. V. Ivanov, who intensively studied and described many of the known species.

Natural History.—Pogonophores dwell in long, cylindrical, secreted tubes composed of chitin and protein. They occur from depths of 750 to 32,000 ft.

The method of obtaining and digesting food among the pogonophores, which lack mouth, anus, and gut, is of great interest. In *Lamellisabella* and *Spirobranchia* the extended tentacles are fused in the form of a cylinder throughout most of their length; in *Siboglinum* the single tentacle is coiled to form a tube. The pinnules, extending into the lumen of the cylinder, intermesh to form a filter. Alongside each pinnule base is a ciliary tract. These tracts produce in each intertentacular region a current of water that carries in microorganisms and detritus that are filtered out by the pinnule mesh. Water leaves by an opening at the base of the ventral tentacles. Digestive enzymes are secreted by gland cells located at the pinnule bases. Digestion is thus external, according to Ivanov, and nutritive material is presumably absorbed by the pinnules. It has also been suggested that at least some pogonophores may absorb dissolved substances resulting from bacterial decomposition of animals and detritus.

Structure and Function.—The body is divided into three regions, each provided with separate coelomic sacs. A short anterior section, including the protosome and mesosome, is separated from a long trunk section, or metasome, by an external constriction and an internal muscular diaphragm. The protosome is drawn out dorsally into a medial cephalic lobe that contains the central nerve ganglion. One to many hollow tentacles, whose cavities are continuous with the protocoel, arise from the ventral side of the protosome, at the base of the cephalic lobe; the tentacles are

FROM A. V. IVANOV, IN "ZOOLOGISCHE JAHRBUCHER ABT. I SYSTEMATIK," 68 (1957)

FIG. 1.—FEMALE SPECIMEN OF SPIROBRANCHIA BEKLEMISCHEVI, VENTRAL VIEW WITH POSTERIOR ONE-SIXTH OF TRUNK NOT SHOWN

provided with lateral projections, or pinnules. The mesosome, with a pair of coelomic sacs, is usually separated from the protosome by a constriction and is marked externally by the bridle, a pair of cuticular ridges on the dorsal side, extending obliquely backward to meet or fuse in the midventral line; the bridle supports the protruding worm on the edge of its tube.

The metasome, also with paired coelomic sacs, is divided into two sections by a pair of oblique, parallel ridges called belts, which are beset with rows of small platelets armed with minute teeth. The first part of the metasome, lying anterior to the belts (the preannular region of Ivanov), bears a ventral groove bordered by low folds, each bearing a row of papillae. In *Siboglinum* these papillae contain multicellular glands or are topped with chitinlike platelets, and probably help the animal to cling to the inner surface of the tube. Behind the midventral groove the papillae decrease in number and are arranged irregularly. A ciliated band, possibly sensitive to chemical changes, runs on the dorsal side of the preannular region. Behind the belts the papillae, with their platelets, are borne in transverse rows ventrally. In primitive genera these structures are scattered irregularly or are absent entirely.

A previously unknown posterior extremity of the body of *Siboglinum*, named the anchor, was described in 1964 by M. Webb who believes it is the true metasome. It is set off from the rest of the body by a narrow waist, and terminates with a sucker. It breaks off readily and tends to remain in the tube.

The body wall comprises an outer cuticle and an epidermis overlying a thin circular, and a thicker longitudinal, muscle layer. A plexus of nerves lies in the epidermis, with a fibrous stratum developed between the basal ends of the epidermal cells. The brain, located in the cephalic lobe, gives off nerves to the tentacles and a middorsal nerve to the hind end of the body. Giant nerve fibres are found in the dorsal cord of some genera.

The closed circulatory system includes a middorsal and a midventral blood vessel. In addition, two pairs of lateral trunk vessels occur in *Siboglinum*. Ivanov reported that the ventral vessel is provided with a muscular heart in the protosome and that its contractions propel blood forward into the tentacular vessels. In the order *Athecanephria* a pericardial sac lies apposed to the dorsal side of the heart. The efferent tentacular vessels carry the blood to the dorsal vessel, in which the flow is posterior. The course of the blood is thus the reverse of that in the Hemichordata, if Ivanov has correctly interpreted the cephalic lobe as a landmark of the dorsal surface of Pogonophora.

Reproduction and Development.—The sexes are separate, differing externally only in the position of the gonoducts. In males, an elongate testis occupies the posterior half of each metacoel. Long sperm ducts run anteriorly and open out behind the septum between mesosome and metasome. The sperm are enclosed in spermatophores bearing long, thin filaments. In females, the ovaries occupy the anterior half of the metasome and have short oviducts that open out in the middle of the trunk. The eggs are relatively large and rich in yolk.

Developmental stages are best known in *Siboglinum*. Development of eggs takes place in the mother's tube. Cleavage leads to the formation of a bilaterally symmetrical embryo with large cells at the posterior end and on the convex side. Gastrulation presumably occurs by delamination without the formation of a blastopore. At a later stage an inner mass of endodermal cells gives rise anteriorly to a median pouch, the protocoeal rudiment, from which paired outgrowths extend posteriorly as the rudiments of the mesocoels and metacoels. Mouth and anus fail to develop,

and the endoderm disappears as its yolk is used up. Later, furrows develop to separate metasome from mesosome, and the latter from the protosome.

Relationships and Classification.—Although several authors had pointed out the affinities of the Pogonophora with the echinoderm-hemichordate-chordate assemblage of animals, it was the work of Ivanov that placed this relationship on a sound basis. The manner of development of the coelomic sacs, the division of the body into three regions, and the structure of the nervous system all point to an especially close relationship with the hemichordates. But details of the arrangement of the coelomic sacs and the openings of ducts to the exterior, the origin of the tentacles from the protosome, the absence of a midventral nerve cord, and the absence of a gut support establishing the Pogonophora as an independent phylum.

Ivanov's proposal, in 1955, to name the new phylum Brachiata which would include the class Pogonophora has not been generally received. The more familiar name of Pogonophora is widely used for the phylum. Ivanov recognizes two orders:

Athecanephria.—The protosome and mesosome are delineated externally by a constriction. Nephridiopores open out laterally. One or a number of separate tentacles are present. A pericardial sac is present. There are no transverse ventral rows of adhesive papillae posterior to the belts.

Thecanephria.—The protosome and mesosome may or may not be marked off by an external constriction. Nephridiopores open out medially. Tentacles are few to numerous, separate or fused basally. There is no pericardial sac. Transverse ventral rows of adhesive papillae are present on the metasome posterior to the belts.

(W. D. H.)

POGROM, a Russian word meaning "devastation" or "riot," came into international use as a result of the wide notoriety given to a number of outbursts against the Jews in Russia between 1881 and 1917. The character of these events was such that the word came to have a particular meaning: a mob attack, either approved or condoned by authorities, against the persons and property of a religious, racial, or national minority.

The first extensive pogroms followed the assassination of Tsar Alexander II in 1881. Although the assassin was not a Jew, and only one Jew was associated with him, false rumours aroused Russian mobs in more than 200 cities and towns to attack Jews and destroy their property. In the two decades following, pogroms gradually became less prevalent; but in 1903 they again began to spread and for a three-year period were common throughout the country. Thereafter, from 1906 to the end of the Russian monarchy, mob action against the Jews was intermittent and less widespread.

The pogrom in Kishinev, in April 1903, although more severe than most, was typical in many respects. For two days mobs, inspired by local leaders acting with official support, killed, looted, and destroyed without hindrance from police or soldiers. When troops were finally called out and the mob dispersed, 45 Jews had been killed, nearly 600 had been wounded, and 1,500 Jewish homes had been pillaged. Those responsible for inciting the outrages were not punished.

The Russian central government did not organize pogroms, as was widely believed; but the anti-Semitic policy that it carried out from 1881 to 1917 made them possible. Official persecution and harassment of Jews led the numerous anti-Semites to believe that their violence was legitimate, and their belief was strengthened by the active participation of a few high and many minor officials in fomenting attacks and by the reluctance of the government either to stop pogroms or to punish those responsible for them.

Pogroms have also occurred in other countries, notably in Poland and in Germany during the Hitler regime. See *ANTI-SEMITISM*; *JEWS: Modern Period*.

POHJOIS-KARJALA (Swedish NORRA KARELEN, North Karelia), a *lääni* (county) of east-central Finland bordering the Karelian Autonomous Soviet Socialist Republic of the U.S.S.R. Pop. (1960) 203,934. It centres on the northeast reaches of Lake Saimaa, there represented by the lake Pielinen. Highest altitudes are reached in the scenically magnificent Koli heights (about 1,000 ft.). Softwood forests are the principal source of income, with small-scale, mixed farming as subsidiary. Joensuu (commune pop. 28,335) is the administrative centre and northern terminal of summer steamboat routes, and contains a fine regional hospital and local museum. Smaller market centres are Lieksa (4,361) and Nurmee (2,165). (W. R. ME.)

POINCARÉ, (JULES) HENRI (1854-1912), French mathematician and philosopher of science, who at the turn of the century was generally acknowledged to be the outstanding mathematician of his age, was born at Nancy on April 29, 1854. He was a first cousin of Raymond Poincaré, president of the French republic during World War I. After attending the École Polytechnique, Henri Poincaré entered the École des Mines. In 1879 he was appointed to a mathematical post at Caen university. In 1881 he moved to Paris university, where he lectured in turn on almost all branches of pure and applied mathematics. He was a prolific writer, producing more than 30 books and 500 original memoirs.

Poincaré's first great achievement was in pure mathematics. He generalized the idea of functional periodicity in his theory of automorphic functions which are invariant under a denumerably infinite group of linear fractional transformations. He showed how these functions can be used to integrate linear differential equations with rational algebraic coefficients and also to uniformize algebraic curves; i.e., to express the co-ordinates of any point of an algebraic curve as uniform functions of a single parameter. The class of automorphic functions which he called Fuchsian, after the German mathematician I. L. Fuchs (1833-1902), he found to be associated with transformations arising in non-Euclidean geometry.

In celestial mechanics he made important contributions to the theory of orbits, particularly in connection with the classical three-body problem. In the course of this work he developed powerful new mathematical techniques, including the theories of asymptotic expansions and integral invariants, and he made fundamental discoveries on the behaviour of the integral curves of differential equations near singularities. His researches on new mathematical methods in astronomy were summed up in his great three-volume treatise *Les Méthodes nouvelles de la Mécanique céleste* (1892, 1893 and 1899). In his theory of periodic orbits he founded the subject of topological dynamics. His memoirs on *analysis situs*, as it was then called, mark the beginning of modern topology.

Poincaré made important contributions to the theory of the figures of equilibrium of rotating fluid masses, and in particular discovered the pear-shaped figures which played so prominent a part in the researches of G. H. Darwin, J. H. Jeans and A. M. Liapunov. But his greatest contribution to mathematical physics was his famous paper on the dynamics of the electron published in 1906. In this paper he obtained, independently of Einstein, many of the results of the special theory of relativity. The principal difference was that Einstein developed the theory from elementary considerations concerning light signaling, whereas Poincaré's treatment was based on the full theory of electromagnetism and so was essentially restricted to phenomena associated with the latter.

Poincaré's writings on the philosophy of science, gathered together in his books *La Science et l'Hypothèse* (1903; Eng. trans., 1905), *La Valeur de la Science* (1904) and *Science et Méthode* (1908; Eng. trans., 1914), were no less important than his contributions to mathematics. He was a forerunner of the modern intuitionist school founded by L. E. J. Brouwer and believed that some mathematical ideas precede logic. In one of the most famous of his essays he made an original analysis of the psychology of mathematical discovery and invention. But the greatest of his

contributions to philosophy was his emphasis on the role played by convention in scientific method.

In his writings on philosophical topics Poincaré revealed himself as a master of French prose and was read by thousands in all walks of life. He was elected to the Académie Française in 1908 to fill the vacancy caused by the death of the poet R. F. A. P. Sully Prudhomme. Poincaré died in Paris on July 17, 1912.

See J. S. Hadamard, *The Early Scientific Work of Henri Poincaré* (1922), *The Later Scientific Work of Henri Poincaré* (1933); T. Dantzig, *Henri Poincaré, Critic of Crisis* (1954). (G. J. Ww.)

POINCARÉ, RAYMOND (1860-1934), French statesman, ninth president of the Third Republic and five times premier, was born at Bar-le-Duc, the son of an engineer. He early showed intellectual powers and won many academic distinctions; and after

a year's military service with the *Chasseurs à pied* he was admitted to practice as a barrister in Paris in 1882. He soon began also to write for newspapers. Elected to the Chamber of Deputies by the Meuse département in 1887, he sat on the left centre and first made his name as an expert on law and finance. He served as minister of education (April-November 1893) and as minister of finance (May 1894-January 1895) under Charles Dupuy and as minister of education again (January-October 1895) under Alexandre Ribot. His bill of 1893 reorganized the university system.

On leaving office, Poincaré was elected vice-president of the Chamber. For several years subsequently he played an important

ROGER VIOLETTE

RAYMOND POINCARÉ. PHOTOGRAPHED IN 1913, THE YEAR HE WAS ELECTED PRESIDENT OF FRANCE

role on the Finance Committee, at the same time enhancing his reputation as a lawyer. Though he was opposed to the Radicals, he was never a reactionary, and at the climax of the Dreyfus Affair he declared himself convinced of the alleged traitor's innocence (see DREYFUS, ALFRED). In 1903 he left the Chamber of Deputies and entered the Senate. His marriage to the widowed Mme Bazire took place in 1904. He accepted the finance portfolio in Ferdinand Sarrien's cabinet in March 1906, but retired when Georges Clemenceau (*q.v.*), whose dictatorial manner he disliked, succeeded Sarrien as premier in October.

Prominent in Parliament, famous as a barrister, and also, from 1909, a member of the French Academy, Poincaré thought that henceforth he could not accept anything less than the premiership, and so declined several other cabinet posts. His time came in January 1912. Joseph Caillaux (*q.v.*), the Radical premier, had conducted a difficult negotiation with Germany without taking much account of the views of his foreign minister, Justin de Selves; and this caused some disquiet in political circles. Poincaré, a member of the Senate's committee of inquiry into the matter, played a part in the scene which led to Caillaux's resignation and was then entrusted by the president of the Republic, Armand Fallières, with the formation of a new government (Jan. 12, 1912).

Stimulated by pinpricks from Germany, patriotism was running high in France; and the new premier, whose patriotism had always been unquestionable, was one whom public opinion could greet with widespread satisfaction. Taking charge of foreign affairs at the same time, Poincaré forthwith undertook to give a new and stronger style to French diplomacy. While he looked askance at Germany and Italy, he devoted himself to strengthening France's links with Russia and Great Britain. On a visit to St. Petersburg in August 1912 he assured the Russian government that his country would stand by the Franco-Russian alliance; and in November he and the British foreign secretary, Sir Edward Grey, concluded an agreement whereby their respective governments should consult one another at moments of international crisis and take

account of plans jointly established by their naval and military authorities. Throughout the Balkan Wars (1912-13), Paris and London cooperated constantly to prevent hostilities from spreading.

As Fallières was approaching the end of his term of office, Poincaré was urged by his friends to stand for the presidency of the Republic. Though he was opposed by the left under Clemenceau's leadership, he was elected president on Jan. 17, 1913, by 483 votes to 376.

Poincaré's supreme ambition was now attained. But he resented being merely a decorative figure at the head of the state and sometimes spoke of the Élysée Palace as "a prison." However, he gave effective support to the governments of Aristide Briand and of Jean Louis Barthou (*q.v.*) in order to secure the voting of the bill that raised the length of compulsory military service from two to three years. The high command judged this move indispensable if France was to compensate Germany's overwhelming superiority in population. When the general election of May 1914 gave the left a majority in the Chamber, Poincaré feared that this Three Years Act might be repealed: for a time he thought of resigning, but finally he decided that his duty was to remain in office, to help France to weather the impending storm.

In July 1914, returning via Scandinavia from an official visit to Russia, Poincaré learned by radio of Austria-Hungary's ultimatum to Serbia and promptly cut short his homeward journey. It was clear that the mechanism of the existing European alliances made war inevitable, and he was welcomed back in Paris with enthusiasm and cheering. Though later he was wrongly represented as having been a warmonger, he in fact sincerely desired peace; but since Germany intended war he saw no other course than to fight it out, with the further hope that the issue might restore to France the territory lost in 1871 (Alsace-Lorraine). In a letter to George V of Great Britain he pleaded for a clear declaration that the Anglo-French entente would, if necessary, prove its strength on the battlefield. Germany declared war on France on Aug. 3, 1914; and on Aug. 4 Poincaré sent a message to both houses appealing for the *union sacrée* of all Frenchmen against the invader. (See WORLD WAR I.)

Throughout the war Poincaré performed his duty energetically but with discretion, never transgressing the narrow limits of his constitutional powers. He gave fresh proof of his patriotic loyalty in November 1917 by entrusting the premiership to Clemenceau, who had recently made bitter attacks on him. Differences of opinion again estranged him from Clemenceau during the peace negotiations, in which his advice was disregarded; and on Feb. 18, 1920, after the completion of his presidential term of office, he was glad to leave the Élysée.

Reelected to the Senate, Poincaré was for a time chairman of the commission on the reparations (*q.v.*) due from Germany. He wrote articles for the press on the necessity of compelling Germany to fulfill the obligations imposed by the Treaty of Versailles. Briand meanwhile was inclined to agree with the British on the subject of reparations; but when he resigned office Poincaré on Jan. 12, 1922, succeeded him as premier and foreign minister. Poincaré failed to reach any understanding with the British; and at a conference held in Paris early in January 1923 he rejected the compromise suggested by Andrew Bonar Law. With the British dissenting, the Reparations Commission eventually declared that the Germans had failed to meet their obligations; and Poincaré, in agreement with Belgium and Italy, then decided that France should occupy the Ruhr (*q.v.*). The "passive resistance" in the area, ordered by the German government, came to an end on Sept. 26, 1923, after the French had retaliated by taking full control of railways and mines there. Though the Ruhr magnates were thenceforward ready for close industrial cooperation with France, Poincaré would not listen to their proposals. He finally accepted the British-U.S. suggestion that a group of experts should deal with the problem of reparations; this resulted in the adoption of the Dawes Plan.

For the first three months of 1924 Poincaré had to face a financial crisis. By inducing Parliament to vote new taxes, he saved the situation, but there was strenuous opposition by the Radicals and the Socialists, united in a *cartel des gauches* or left bloc. His fi-

nance minister, Charles de Lasteyrie, resigned on March 26, and Poincaré reconstituted his cabinet two days later. The general election of May 1924 gave the cartel a majority, and on June 1 Poincaré resigned.

Further deterioration of the French finances, which successive cabinets had been unable to remedy, brought Poincaré to power once more. On July 21, 1926, the exchange rate of the franc fell to 48 to the U.S. dollar (as against 5 in 1914). Next day Poincaré was appointed premier and formed a coalition government, taking the portfolio of finance for himself and giving that of foreign affairs to Briand. Public opinion was immediately appeased, and with the help of a few technical measures Poincaré restored confidence in the franc, which by the end of the year stood at 24 to the dollar. The next difficulty was to prevent this rise of the franc from continuing to a point at which French exports would be adversely affected; but Poincaré succeeded in maintaining a stabilization *de facto* for a year and a half. The general election of April 1928 returned a majority in favour of Poincaré's policy, and in June he obtained the passing of a bill establishing his stabilization *de jure* and basing the French franc on gold again. It was altogether one of the most successful operations of its kind in history.

The withdrawal of the Radical ministers from his cabinet caused Poincaré's resignation on Nov. 7, 1928, but he formed a new government immediately. France was now prosperous, and the premier's prestige was unbounded. In spring 1929 he tried to induce Parliament to ratify the agreements negotiated in Washington and London on Inter-Allied debts, but his efforts had strained him too far, and he fell dangerously ill. He resigned office on July 26, 1929. Never fully recovering health, he occupied himself with the continuation of his memoirs, *Au service de la France*, ten volumes of which appeared between 1926 and 1933. He died in Paris on Oct. 15, 1934.

Supremely clever, deeply learned, fastidiously scrupulous, Poincaré sometimes revealed a sort of narrow-mindedness. But on the whole he was a great man of honour, a very able statesman, and a great Frenchman.

See S. Huddleston, *Poincaré* (1924); J. Chastenet, *Raymond Poincaré* (1948).

POINCIANA, a genus of tropical and subtropical shrubs or small trees (usually not more than ten feet high) of the pea family (Leguminosae), grown for their showy orange or yellow and red flowers. The best-known species are the Barbados pride, or dwarf poinciana (*P. pulcherrima*), and the bird-of-paradise bush (*P. gilliesii*), both of which are widely grown in warm regions. *Poinciana* is sometimes included in the genus *Caesalpinia*.

The royal poinciana is a different but closely related ornamental tree (see FLAMBOYANT TREE).

POINSETT, JOEL ROBERTS (1779-1851), U.S. statesman noted primarily for his diplomacy in Latin America, was born on March 2, 1779, in Charleston, S.C. He was educated in England and the United States. In 1810 he became a special agent for the United States in Buenos Aires and Chile, initiating diplomatic relations with those states. Poinsett was elected to the South Carolina legislature in 1816 and two years later won election to the U.S. House of Representatives. He went on a special governmental mission to Mexico in 1822 and 1823, and in 1824 published *Notes on Mexico*, a book describing his experiences. In March 1825 he gave up his seat in Congress to become the first minister to Mexico, a post he held until December 1829.

In 1830 Poinsett became a leader of the Unionist Party in South Carolina, a group that opposed those who sought to carry John C. Calhoun's doctrine of nullification into effect. As a reward for his services in that controversy, Pres. Martin Van Buren appointed him secretary of war, a post he held with distinction for four years. In 1841 he retired to his plantation in South Carolina where he opposed the growing secessionist movement in his state. He died near Statesburg, S.C., on Dec. 12, 1851.

Poinsett's varied intellectual interests included the fine arts, agriculture, and botany. He was honoured by having the flower he brought from Mexico, the poinsettia, named after him. His main contribution to learning was his work in helping to found the Na-

tional Institute for the Promotion of Science and the Useful Arts in 1840, a precursor of the Smithsonian Institution. Poinsett was one of the most versatile and cosmopolitan Americans of his time.

(A. DEC.)

POINSETTIA, a showy tropical shrub of the spurge family (Euphorbiaceae; *q.v.*), native to Mexico and Central America. It is a traditional flower of the Christmas season, known scientifically as *Euphorbia pulcherrima*, the latter term meaning most beautiful. The poinsettia was named after Joel R. Poinsett of Charleston, S.C., who introduced the plant to the United States in 1828 when he was minister to Mexico. The true flowers of the poinsettia are inconspicuous, forming a yellow cluster in the centre of the red, white or pink bracts. In the rarer double poinsettia most of the flowers have been transformed into bracts giving a more showy effect. The poinsettia is abundantly used as a yuletide gift plant in the north, while in Florida and other tropical lands it is a popular flowering shrub.

COMMON POINSETTIA (EUPHORBIA PULCHERRIMA)

When used as a gift plant it should be placed in a room with constant temperature as it cannot tolerate drafts or fluctuating temperatures. It needs plenty of water while blooming. Although it is possible to carry a plant over from one year to the next, it is not advisable unless greenhouse facilities are available. Poinsettias are propagated by cuttings in March.

POINTE-A-PITRE, the principal town of Guadeloupe (*q.v.*) in the French Antilles, is situated on the southwest coast of Grande-Terre, the low-lying island which forms the eastern half of Guadeloupe. The town lies on the east shore of the estuary of the Rivière Salée, a channel that connects two large bays to north and south and separates Grande-Terre from Basse-Terre, the mountainous western half of Guadeloupe. Several islets in the southern bay guard the approach to the harbour of Pointe-à-Pitre, and in the vicinity of the town there are extensive mangrove swamps. The total population (1962) was 27,737.

Pointe-à-Pitre was founded in the mid-17th century, soon after the French settlement of Guadeloupe, but it was eclipsed in importance by Basse-Terre, which still remains the administrative capital. In 1906 a road bridge across the Rivière Salée replaced the existing ferry and, favoured by its central position and harbour facilities, Pointe-à-Pitre became the chief commercial town. Near the centre of the town there are many old houses with stone lower and wooden upper stories; in the mid-20th century there was extensive suburban development, particularly north toward Raizet Airport and the nearby town of Les Abymes.

(D. R. H.)

POINTE-NOIRE, the principal port of the Congo Republic, west-central Africa, lies 316 mi. W of Brazzaville, at the terminus of the Congo-Ocean Railway line which was built to avoid the rapids of the lower Congo River. Pop. (1958) 54,573, including about 3,000 Europeans. It was the country's capital from 1950 to 1958. The so-called European town developed in three distinct areas. To the west is the plain, across a marshy dip partly filled up; the plateau, a slight well-drained rise, is the residential quarter; to the south along the road to the airport is an industrial district with timber and engineering works. The inhabitants of the European town are chiefly French, with some Portuguese traders. Alongside old houses in Norman style with gardens are buildings of concrete. The plateau also contains the shopping centre, hospital, mission houses, cathedral, oceanography centre, and schools. Northeast of the plateau, in the swampy valley of the Tchinouka, the African village was created. The Africans come from all parts and include about 140 ethnic groups. The huts are often in the traditional style, of wood, dried mud, or brick with palm-leaf roofs. The need for settled workers led to the building of a new town,

Tie-Tie, where many houses are of more durable materials.

The port, on the Atlantic Ocean, stands on a calm bay, protected by breakwaters and approached through a well-cleared fairway. Begun in 1934, it was opened in 1939. Because of World War II the installations, including an oil store, workshops, and repair yards, were only completed in 1946. There is a factory producing phosphorous cellulose, and plans were made for an industrial combine, using hydroelectric power from the Kouilou, to treat iron from Mekambo and manganese from Franceville.

(J. D.)

POINT SET, in mathematics, is a collection of points selected from a given space. Generally speaking, the properties of a point set may be classified as topological or metric. For a description of the former see TOPOLOGY, GENERAL. A brief introduction to the metric properties of point sets follows.

The Problem of Measure.—Consider the simple example in which the given space is an ordinary straight line L . If P and Q are distinct points of L , then the point set consisting of P and Q together with all points between them is called an interval, denoted $[P, Q]$. A common foot rule can be applied to L , and the interval $[P, Q]$ can be measured as a certain number of feet. The length of a single point, in accordance with ordinary geometry, is zero. If two intervals have no point in common, it is not customary to speak of the length of the set of points they represent, the word length being usually applied only to connected pieces. In this case the word measure is used; the measure of this point set is the sum of the lengths of the two intervals.

However, to speak of a point set on L does not necessarily imply an interval, a single point, or a set of intervals; it sometimes means a set of points that contains no connected portion; *i.e.*, no interval. Since a point has length zero, the measure of such a set might be expected to be the sum of the lengths of its individual points; *i.e.*, the sum of a set of zeros, and hence zero. However, if we determine upon a measure for two point sets A and B which have no points in common, the sum of their measures should be the measure of the point set comprising A and B taken together. Thus, above, it is stated that the measure of a set of two intervals with no common point is the sum of the lengths of those intervals. Any interval $[P, Q]$ can be shown to be the sum of two sets A and B each of which fails to contain any interval, and if the measure of both A and B is arbitrarily called zero, the sum of their measures would be zero, which is not the length of $[P, Q]$, no matter how small. In other words, a measure of a set of points is wanted that will correspond to the ordinary idea of length.

This has introduced what is known in the theory of sets of points as the problem of measure. Among several methods devised for finding a measure of an arbitrary set of points, the theory of Lebesgue measure is the foundation of the theory of integration (see INTEGRATION AND MEASURE: *The Extension Period*).

Lebesgue Measure.—Any set A is said to be covered by a collection G of intervals, when every point of A is in some interval of G . If the set of intervals G is denumerable, then it is said to be a covering of A . (The set is called denumerable if its elements can be tagged with positive integers in such a way that no two elements of the set are tagged with the same integer.) If the sum of the lengths of the intervals of G exists, let this be called the sum-length of the covering. Of all possible coverings of A consider the corresponding sum-lengths, and let N be the largest number that is not greater than any of these sum-lengths. Then N is called the exterior (outer) measure of A and is denoted $m_e A$. Suppose, now, that $[P, Q]$ is some interval of length d , such that all points of A are within $[P, Q]$. Let B be the set of all points of $[P, Q]$ that do not belong to A , and let $m_e B$ denote the exterior measure of B , found just as $m_e A$ was found. If it happens that $m_e A + m_e B = d$, then $m_e A$ is accepted as the measure of A and is what is known as the Lebesgue measure of A . At the same time $m_e B$ is the Lebesgue measure of B , and in accordance with ideas of length it is required that the sum of the two measures give the length of $[P, Q]$. To be sure, the Lebesgue measure of a set of points may not exist, but it does exist for all ordinary point sets. Indeed it is not easy to give an example of a set of points with no Lebesgue measure; all examples that have been given use methods unacceptable to many mathematicians.

For the measure of a set of points in a plane, areas are employed. Thus, the measure of the set of all points in a square is the area of the square. And to get the measure of a general plane point set M , a covering of M is made by means of squares. In three dimensions cubes are employed, and concern is with sum-volumes.

The introduction of the notion of measure led to an enrichment of general analysis that hardly could have been realized otherwise. The effect has been felt not only in mathematics itself, but in the closely allied fields of mechanics and dynamics. See also SET THEORY (THEORY OF AGGREGATES); FOURIER SERIES.

POISON is a substance that, when taken into the mouth or stomach, or when absorbed into the blood, is capable of affecting health seriously or of destroying life by its action on the tissues with which it comes into contact immediately or after absorption. Toxicology is the science that embodies the knowledge of the sources, characters and properties of poisons, the symptoms they produce, the nature of their fatal effects and the remedial measures that should be employed to combat their actions or effects.

Sale of Poison.—In the United States, the Caustic Poison act, 1927, safeguards the distribution and sale of certain dangerous caustic or corrosive acids, alkalies or other substances in interstate and foreign commerce. This act names 12 materials which are classified as dangerous, caustic or corrosive substances: hydrochloric acid, sulfuric acid, nitric acid, carbolic acid, oxalic acid, salt of oxalic acid, acetic acid, hypochlorous acid, sodium hydroxide, potassium hydroxide, ammonium hydroxide and silver nitrate. The Federal Food, Drug and Cosmetic act, 1938, successor of the Food and Drugs act, 1906, prohibits the movement in interstate commerce of adulterated and misbranded food, drugs, devices and cosmetics. Both the Caustic Poison act and the Federal Food, Drug and Cosmetic act are enforced by the Food and Drug administration. The U.S. public health service administers the Virus, Serum and Toxin act, 1902, which provides for the maintenance of potency and purity of biological products. The Harrison Narcotic act, 1914, and the Marihuana Tax act, 1937, are administered by the bureau of narcotics of the U.S. treasury department. These acts regulate the importation, sale or giving away of preparations of opium or coca leaves and of marijuana, respectively.

The following are the statutes governing the sale of poisons in Great Britain: Pharmacy and Poisons act, 1933; Poisons rules, 1935; Poisons (Colouring) rules, 1936; statutory rules and orders made in connection with the Pharmacy and Poisons act, 1933; Dangerous Drugs act, 1951; and statutory regulations and orders made in connection with them; Therapeutic Substances act, 1925; and Therapeutic Substances regulations, 1931-44.

The objects of these acts, put broadly, are to control the sale of poisons to the public and to reduce the danger to human life from indiscriminate sale by unqualified persons. The Dangerous Drugs acts regulate the use of drugs of addiction such as opium, morphine and cocaine. With certain exceptions, only duly qualified and registered pharmacists and registered medical practitioners are permitted to sell poisons.

Poisoning.—Poisoning may be accidental, suicidal or homicidal. By far the commonest type is poisoning from accidental causes. In spite of the precautions taken by the state in the sale of poisons, far too little care is taken by the public in the safeguarding of poisons in their possession. As a result, these are frequently taken by mistake instead of other substances of a harmless nature, or often an overdose is taken from pure carelessness. Thus, oxalic acid crystals when purchased in a paper packet may be transferred to an unlabeled bottle or jar and then taken by mistake for Epsom salts, which they closely resemble. Similarly, tablets of corrosive sublimate (mercuric chloride) have been taken by mistake. It is the duty of every person possessing a substance of poisonous nature to take the utmost care that this is correctly labeled and kept safely guarded under lock and key.

Two poisons very commonly responsible for poisoning are Lysol and carbon monoxide. Both are usually present in the average

home. Carbon monoxide is responsible for many deaths yearly as a result of accident or suicide. It is a constituent of illuminant gas; for example, town gas, when prepared in the vertical retort, may contain as much as 22% of carbon monoxide. Defective gas heaters, especially in bathrooms, and fractured gas pipes and mains may provide a source of poisoning. Exhaust gases from internal-combustion engines also cause poisoning. It has been estimated that such gases contain from 1% to 7% depending on the richness of the mixture. Self-administration of barbiturates is a dangerous practice, since the patient having already become confused by an initial dose of a barbituric compound may continue, on the same occasion, to take further and possibly fatal quantities of the drug without realizing the danger. This is the possible explanation of some of the acute and even fatal cases of barbiturate poisoning which might otherwise appear inexplicable.

ACTION OF POISONS

Poisons may have a local action or a general systemic action after absorption into the circulatory system, or they may act in both ways. Almost all poisons have a general systemic action. Some poisons such as corrosives destroy the mucous membrane or tissues with which they come in contact and cause serious or dangerous injury thereby. Irritant poisons set up a local inflammatory reaction in the mucous membrane of the alimentary tract.

Apart from these local effects, the common result of absorption of a poison is the harmful effect produced on the important organs of the body; for example, the liver, kidneys, heart and nervous system are almost certain to be adversely affected. A poison after absorption attacks all the organs of the body in varying degrees, and it is a mistake to regard poisons as being exclusively selective in their action though some poisons appear to direct the brunt of their attack on a particular system.

Among the conditions affecting the action of a poison may be mentioned the following:

Amount Taken.—From the point of view of dosage, potent drugs can be divided, in an arbitrary manner, into two groups: those in which the lethal dose lies far in excess of the active dose, and those in which it lies close to the active dose. There is a definite distinction between the terms "toxic dose" and "fatal dose," since the former merely causes symptoms of poisoning while the latter induces poisoning to such a degree that death results. The term "fatal dose" when applied to a poison means the smallest dose which is known to have caused death in an adult. Usually the quantity of a poison taken bears a relation to the effects produced. Exceptions to this rule are substances in the case of which, as a result of the quantity taken, vomiting occurs so that most of the poison is expelled; oxalic acid and tartar emetic are examples. Frequently larger doses may be taken without death resulting, but much depends on other factors than quantity, and also on whether adequate treatment has been instituted.

Habit.—A tolerance to some poisons occurs after their repeated use, and in some cases doses far greater than a normal fatal dose may be tolerated without serious symptoms developing. Examples of such drugs are arsenic, morphine, opium, cocaine and alcohol. In the case of some of these poisons their repeated use leads to addiction, with all its pernicious symptoms and effects.

Idiosyncrasy.—Some persons are exceedingly intolerant of certain drugs which in moderate doses may thus cause in them dangerous or even fatal symptoms. Examples are morphine, cocaine, quinine, iodine, bromine, salicylates and acetylsalicylic acid (aspirin), which in some persons have a severe cardiac depressant action.

Age.—Usually children are much more susceptible to the effects of a poison than adults. The dosage of drugs in the case of children has been fixed by a pharmacological rule, but exceptions to this are morphine, opium and its preparations which are much more toxic than the rule would indicate; on the other hand, children tolerate belladonna preparations better than adults. Aged persons withstand poisons badly.

State of Health.—A relatively small dose, from which a stronger person would probably recover, may kill a weakly person. In disease, drugs are usually much more toxic, and this is especially so when the excretory organs are affected. For example, in nephritis, medicinal doses of such drugs as morphine, salvarsan, hyoscine, etc., often cause dangerous symptoms; likewise in cirrhosis of the liver there is a greatly increased susceptibility to such drugs. In conditions of gastritis or enteritis, drugs like arsenic are especially toxic. On the other hand, in some conditions associated with delirium or pain, large doses of sedative drugs produce little effect provided the excretory organs are healthy.

Condition and Mode of Administration.—If a poison is taken in solution by the mouth, it acts much more powerfully than if taken in an insoluble form. For example, an insoluble preparation of arsenic may produce little poisonous effect even in large doses; similarly strychnine given in hard pills has a much-delayed action.

The presence of food in the stomach has a marked influence on the effect of a poison. If the stomach is empty the effect will be rapid, particularly so when the poison is in a soluble form; on the other hand, if the stomach is full, considerable delay may occur in the action of the poison as is well shown in acute arsenical poisoning.

A poison acts most rapidly when inhaled in a gaseous or vaporous form or when injected intravenously; next in order of rapidity, when injected subcutaneously; and least rapidly when ingested. Poisons may be absorbed by the skin or mucous membrane of the vagina or rectum, with fatal result.

Chemical Combination.—Some substances when in certain combinations are very poisonous, but when in others are comparatively innocuous. While the component parts of a mixture may have a poisonous action when administered singly, the compound may be comparatively inert.

Cumulative Action.—Certain poisons tend to accumulate within the body as the result of slow excretion (for example, strychnine, lead, mercury, digitalis and carbon monoxide) and therefore the continued administration of relatively small doses may occasion symptoms of poisoning.

DIAGNOSIS AND TREATMENT OF POISONING

Evidence of Poisoning.—It must be remembered that the symptoms of poisoning may be closely simulated by the symptoms of natural disease, and the greatest care must be taken before a diagnosis of poisoning is arrived at. Thus, the symptoms of acute arsenical poisoning closely resemble those of cholera or of acute bacterial food poisoning. The only certain differentiation is the finding of arsenic in the vomit, feces or urine, or of the bacteriological evidence of a cholera or food poisoning infection.

Various factors may provide evidence of poisoning: (1) The symptoms are usually sudden in their onset and they occur after the taking of food or drink, or after exposure to poisonous gases or vapours. (2) If several persons are similarly exposed all are affected more or less with similar symptoms. An exception may occur in the case of bacterial food poisoning, where certain persons may be relatively immune and some may be specially susceptible. (3) The analysis which should always be carried out in suspected cases may reveal the presence of the poison in the vomit, urine and feces, and possibly also in some articles of food or medicine.

Post-mortem Evidence.—If death occurs, a post-mortem examination should be made only following instructions from the appropriate official. The post-mortem signs found should be consistent with those occurring from poisoning by the suspected poison. The analysis of the viscera should yield results consistent with that of poisoning by the suspected poison, taking into account the circumstances of administration and death.

Treatment.—The mode of treatment to be adopted varies according to the nature of the poison. The poison should be removed from the stomach without delay, antidotes should be administered, the poison should be eliminated from the body by natural channels, symptomatic treatment should be undertaken and stimulation of the respiratory and circulatory systems should be resorted to as soon as indications present themselves. Emetics

are a poor substitute for the emptying and washing out of the stomach by means of the funnel and stomach tube, but they may be employed if the more effective treatment is impossible. Safe emetics are mustard and water, salt and water, ammonium carbonate or apomorphine. The emptying and washing out of the stomach by means of the stomach tube and funnel is, however, contraindicated when poisoning occurs from the corrosive mineral acids or alkalies. In such cases there is a danger of perforation. After the stomach has been emptied and washed out, suitable antidotes should be given, such as chalk and lime water to neutralize oxalic acid and the mineral acids, lime water for carbolic acid. Atropine may be given hypodermically in the case of morphine poisoning. Where morphia and cocaine are taken, the stomach should be washed out with diluted permanganate of potash solution.

Elimination by the bowel is facilitated by colon washes with warm normal saline solution and by free bowel evacuations. The symptoms of poisoning are subdued by the administration of appropriate remedies; thus, pain may be relieved by hypodermic injection of morphine, and the convulsions from strychnine by chloroform inhalation.

CHARACTERISTICS OF DIFFERENT POISONS

Poisons may be classified in many different ways; *e.g.*, according to their chemical composition, to their action on the body, to their physical characters, etc.

The following is a convenient and simple classification.

1. Corrosive poisons are those which destroy by direct action the tissues with which they come in contact. To this category belong the mineral acids, such as sulfuric, hydrochloric, nitric, etc.; the caustic alkalies, such as caustic soda, caustic potash, ammonia, carbolic acid; metallic poisons, such as corrosive sublimate, zinc chloride, silver nitrate. The last mentioned will also be considered under irritant poisons. It should be remembered that corrosive poisons in diluted condition lose their corrosive effect and become irritants.

2. Irritant poisons, by their direct action on the mucous membrane, set up inflammation. Examples are: oxalic acid and its soluble salts; arsenic compounds and antimony compounds; most of the metallic poisons in solution; phosphorus; bromine; iodine; boracic acid, etc.

3. Systemic poisons which act on the nervous system or other important organs such as the heart, liver, lungs or kidneys without having any special irritant or corrosive effect. This group includes the majority of poisonous substances such as the vegetable poisons or their alkaloids, hydrocyanic acid and its salts, chloral, chloroform, alcohol, ether, hypnotic drugs such as Veronal, sulfonal, etc. Certain poisons affect the liver and produce toxic jaundice (for example, tetrachlorethane, trinitrotoluene, picric acid, etc.), while others, such as cantharides and turpentine, involve the kidneys.

4. Gaseous poisons such as chlorine, carbon monoxide and coal gas, carbon dioxide, etc.

5. Poisonous foods such as mushrooms, shellfish and food contaminated with dangerous pathogenic bacteria.

CORROSIVE POISONS

Symptoms.—Corrosive poisons produce severe symptoms as soon as they are taken—a burning pain in the mouth, throat and esophagus and pain referred from the stomach and intestines. Vomiting occurs quickly and the vomit, which contains blood, may be altered in colour by the action of the poison; often also shreds of destroyed mucosa are present. Collapse occurs early; and perforation is common when, should the patient survive, signs of general peritonitis develop.

An examination of the patient will show signs of the corrosive action of the poison on the mouth and throat, and marked tenderness will be present on palpation over the stomach and intestine. Corrosive poisons if swallowed in poisonous quantity are usually fatal within 24 hours unless immediate treatment with a suitable antidote is adopted.

Should the patient survive the immediate effects of the poison, serious aftereffects result from damage to the alimentary tract, and in the case of volatile corrosives serious pulmonary compli-

cations often ensue. Post-mortem examination shows evidence of the destructive action of the poison on the mucous membrane of the mouth, throat, esophagus and stomach, there being often extensive hemorrhage in the underlying tissues.

Several examples of corrosive poisons will now be discussed.

Corrosive Mineral Acids.—These include *sulfuric acid*, sometimes known as oil of vitriol; this is used in various industries and in all chemical laboratories. It is a most powerful corrosive in the concentrated form, whether taken internally or applied externally as in cases of "vitriol throwing." One dram has caused death in an adult, and half that quantity in a child.

Hydrochloric acid is known also as muriatic acid or spirits of salts. It is used largely for industrial and chemical purposes and is a common article of domestic use. It is readily obtainable and is very commonly used for suicidal purposes. It is a most dangerous corrosive and one dram has caused death in an adult.

Nitric acid, known as aqua fortis and red spirit of nitre, is used for industrial and chemical purposes. It is a most dangerous corrosive and produces characteristic yellow staining of the tissues with which the strong acid comes in contact. The vapour of the acid, if inhaled into the lungs, often produces an acute fatal form of pneumonia, which is a common cause of death in nitric acid poisoning.

Other mineral acids such as *hydrofluoric*, *phosphoric* and *sulfuric* acids in concentrated form produce similar effects.

The treatment of poisoning by corrosive mineral acids consists in giving as soon as possible harmless alkaline remedies such as magnesia powder, milk of magnesia, lime water or chalk. These should be administered freely, and plenty of egg albumen (white of egg) should also be given, since this tends to neutralize the acid by forming a protein combination, and also it has a soothing effect on the damaged mucosa.

The stomach should not be washed out for fear of perforation. Pain is relieved by the free use of morphine hypodermically, and after the swallowed acid has been neutralized food by mouth should be withheld and normal saline should be given rectally as freely as can be retained. In urgent cases of circulatory shock, caused by fluid loss and blood concentration, continuous intravenous infusion of normal saline, or saline with glucose, should be carried out.

Caustic Alkalies.—Among these may be named the following: *caustic potash*, or potassium hydroxide or potash lye, is a powerful corrosive, and *potassium carbonate*, known as salt of tartar, has a similar but less powerful effect. Both are used industrially. Forty grains of caustic potash have caused death.

Caustic soda, or sodium hydroxide or soda lye, is a powerful corrosive and quite as dangerous as caustic potash. It is commonly used industrially.

Ammonia, liquid ammonia or spirits of hartshorn is used largely for domestic and industrial purposes. It is also used in the form of smelling salts when mixed with carbonate of ammonia. It is a powerful corrosive poison and in addition the vapour has a very injurious effect on the lungs, giving rise to bronchopneumonia which may assume a septic type.

As regards treatment following ingestion, harmless acid drinks such as diluted vinegar, lemon juice, citric or tartaric acid should be given freely. Olive oil or egg albumen may be usefully employed. Pain should be relieved by the free use of morphine hypodermically and nourishment should not be given by the mouth, but rectal feeding should be adopted.

Corrosive Organic Acids.—*Carbolic acid*, or phenol, is commonly used as a disinfectant for domestic and surgical purposes. Allied preparations such as creosote or cresol have a similar poisonous effect. Lysol is a combination of cresol with soap and is similar in action to phenol.

Carbolic acid and the allied substances have a powerful corrosive action causing necrosis of the tissues with which they come in contact, the superficial part of which becomes of whitish appearance, the deeper parts becoming dark red as a result of hemorrhage into them. Carbolic acid is one of the poisons most frequently used by suicides, and because of its common use for domestic purposes it is often a cause of accidental poisoning.

The symptoms caused by carbolic acid are those of corrosive poisoning, but because of its local anesthetic action vomiting may be absent and pain may be less marked. If death does not result from shock, the profound effect of the poison on the nervous system causes paralysis of the respiratory and cardiac centres, with rapid feeble pulse and stertorous breathing; coma develops in severe cases and is usually followed by death. Death has also resulted from absorption by the skin, and from rectal injections in solution. Usually death occurs within three to four hours following ingestion of a large dose.

The aim of treatment is to limit the absorption of the poison, to sustain the patient and to aid the elimination of the poison from the system. The stomach should be washed out by means of a soft stomach tube with diluted saccharated lime water or fresh lime water; by this means the phenol is converted into calcium phenate, which is not poisonous. Alternatively, thorough gastric lavage, using a 10% solution of glycerin, or plain water, should be carried out without delay until the washings no longer emit an odour, and a quantity of medicinal paraffin should be left in the stomach. Egg albumen, since it precipitates phenol, will delay absorption. When necessary, rectal feeding should be adopted for several days.

IRRITANT POISONS

The more important irritant poisons will be considered under this heading (*see list, above*), but it must be remembered that many of the general poisons (*e.g.*, *savin*, *cantharides*, etc.) have an irritant action on the stomach and intestines in addition to their special action on important organs and nerve centres.

Oxalic acid occurs in colourless crystals resembling Epsom salts; it is very soluble in water. *Salts of sorrel* or *salts of lemon* is the quadroxalate of potash; it is a white powder very soluble in water. Both of these substances are commonly used for domestic purposes; *e.g.*, for cleaning straw hats, removing ink stains, cleaning brasses, etc. They are frequently the cause of accidental and of suicidal poisoning. When these agents are swallowed in solution the typical symptoms of irritant poisoning are set up, but in addition the poison when absorbed into the system has a profound depressant action on the heart and nervous system. Thus an acid burning taste is experienced and pain occurs which is referred from the throat, esophagus and stomach and later possibly from the intestines. Vomiting is common, the vomit being very acid, and giving positive results to the tests for oxalic acid. It often contains blood. Unless immediate treatment is adopted collapse speedily occurs, the patient becoming cold, pale and faint with a rapid feeble pulse; at this stage death from syncope may occur. In some cases nervous symptoms such as tinglings and numbness, muscular spasms, convulsions, delirium and coma occur, but these symptoms are uncommon. Because of the rapid absorption of the poison, death is likely to occur rapidly (*e.g.*, within an hour), but it may be delayed.

For treatment, fresh lime water or, preferably, saccharated lime water, which is 15 times stronger, should be given in large quantities and it should be mixed with calcium carbonate in the form of chalk or whiting. Since oxalic acid has only slight corrosive action the stomach should be washed out immediately if no antidote is at hand. It is best to give the antidote freely if immediately available and after a few minutes to wash out the stomach thoroughly with a soft stomach tube and funnel, and then finally introduce a pint of lime water made into a thin cream with an ounce of chalk, leaving this mixture in the stomach. Intravenous injections of calcium chloride or gluconate (calcium Sandoz) are recommended.

Arsenic is the most important of the irritant poisons and because of the tasteless property of many of its compounds and preparations it is the commonest poison used for homicidal purposes.

The most notable and commonest compound is arsenious acid, arsenious oxide or white arsenic. It exists in the form of a white powder or in lumps of a white porcelainlike appearance. The powdered form resembles powdered sugar or flour and when mixed with food is almost tasteless. It is sparingly soluble in cold water, which will dissolve only 0.03 to 0.06 g. in 30 ml. About 4 g. in

30 ml., however, will be held in boiling water. When mixed with alkaline substances, white arsenic becomes freely soluble.

Commercial preparations containing white arsenic mixed with alkalies such as sodium hydrate or carbonate are weed killers, sheep-dip and wood preservatives, which may contain from 20% to 40% of white arsenic. Copper arsenite (Scheele's green), lead arsenate and other arsenical preparations are used as insecticides for the spraying of fruit trees. Rat poisons may contain arsenic as the active ingredient. Wallpapers which formerly often contained green pigment (Scheele's green) or the yellow sulfides of arsenic are now coloured with arsenic-free pigments, arsenic being prohibited from use. White arsenic, if sold for other than medicinal purposes, must be mixed with a dye of distinctive colour which is water soluble.

Accidental contamination of food with arsenic has occurred in the past. For example, in 1900 a beer poisoning epidemic occurred as the result of brewing beer with commercial glucose that contained arsenic. Prosecutions have been brought for the presence on apples of prohibitive amounts of arsenic alleged to have been caused by spraying of trees.

When arsenic is taken by the mouth in poisonous quantities, symptoms of acute gastrointestinal irritation such as vomiting, diarrhea and abdominal pain usually occur within a few hours. Death may ensue within a period varying from several hours to several days. A dose of 0.12 g. of arsenic has caused death, though larger quantities have been taken without fatal result. In acute arsenical poisoning the heart, kidneys and other organs are seriously affected so that the poison has a systemic action in addition to its irritant effects on the stomach and intestines.

Chronic arsenical poisoning occurs when small quantities of arsenic are absorbed over long periods. The gastrointestinal symptoms may be slight, but other symptoms, such as gradual loss of weight, alopecia, skin rashes and pigmentation and conjunctivitis, become manifest.

In suspected acute arsenical poisoning the diagnosis can be made certain by analysis of the vomit, urine and feces. In chronic cases additional information may be obtained by analysis of the hair and nails.

Antimony is an irritant poison like arsenic. Tartar emetic or potassium antimony tartrate is one of the most commonly used compounds. It has on several occasions been used for homicidal purposes because of the possibility of its being administered without detection by taste or smell.

Metallic poisons if taken by the mouth give rise to irritant poisoning. Examples are:

In large doses, the common salts of *lead* will cause gastrointestinal irritation. Acute poisoning by lead is rare. Chronic lead poisoning is caused by continued absorption of small quantities of lead and is a dangerous condition as it causes disease of the kidneys, blood vessels, heart and nervous system. Lead tetraethyl is a very poisonous organic compound of lead. It is used commercially as an additive to gasoline, to counteract "knocking" or "pinging" in automobile engines. On inhalation in sufficient quantity it is extremely toxic. The sulfate of *copper* (blue vitriol) and other copper compounds are irritant poisons. The use of copper salts as a colouring matter of foodstuffs such as preserved green vegetables is reprehensible, and has often led to legal action. The Public Health (Preservatives, etc. in Food) regulations of England, 1925-40, prohibited all save scheduled colours and limited the preservatives to benzoic and sulfurous acids and sodium or potassium nitrate, and these only in specified amounts in certain foods.

Zinc salts are irritant poisons. The sulfate of zinc (white vitriol) occurs in crystals that resemble Epsom salts, for which it has been taken in mistake. Zinc chloride has a corrosive as well as an irritant action.

Barium salts, except for the quite insoluble sulfate, are irritant poisons and may also act on the cardiovascular or nervous system.

Chromates, especially potassium bichromate, are powerful irritant poisons.

The yellow variety of *phosphorus* is intensely poisonous and formerly was widely used in the manufacture of matches. Yellow

phosphorus is used as a constituent of some vermin exterminators. The substance, in addition to being a gastrointestinal irritant, is a deadly poison to the liver and kidneys.

Acute *mercurial* poisoning usually arises from the taking of mercuric chloride (corrosive sublimate) or from the biniodide of mercury, both of which are extensively used as disinfectants for medical purposes. The immediate symptoms are those of acute gastrointestinal irritation (vomiting, abdominal pain and diarrhea) but they are generally followed by suppression of urine and symptoms of acute ulcerative colitis, which commonly results in death. Chronic mercurial poisoning is characterized by inflammation of the mouth and gums.

SYSTEMIC POISONS

The systemic poisons include the following:

Prussic or Hydrocyanic Acid.—Hydrocyanic acid is one of the best known poisons and a very deadly one. In the pure state it is said to kill with lightninglike rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopoeial acid, containing 2% of anhydrous prussic acid, and Scheele's acid, containing 4% to 5%. About four millilitres of the 2% acid may cause death.

Hydrocyanic acid and the cyanides must be regarded as true protoplasmic poisons since they arrest the activity of all forms of living matter by inhibiting tissue oxidation and suspending vital functions. Such poisons not only inhibit the enzymic activities, but also act upon the central nervous system.

Given in fatal doses, prussic acid produces symptoms of poisoning with great rapidity; and, in consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before loss of consciousness. There is first a very brief stage of difficult breathing and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely dilated pupils of the eye, the patient is then seized with violent irregular convulsive movements. The rhythm of the respiratory movements is disturbed, and the countenance assumes a bluish colour. The patient collapses with complete loss of muscular power; and the third or asphyxial stage is reached, in which there are slow gasping respirations, loss of pulse and paralysis of motion. Death is frequently preceded by spasms. The lightninglike character of the illness and the speedy death of the patient, coupled with the peculiar odour of the acid in the breath and atmosphere around the body, seldom leave any doubt as to the nature of the case.

Other soluble cyanides, more especially cyanide of potassium, a salt largely used in photography and in the arts, are highly poisonous but are slightly less rapid in action than hydrocyanic acid.

When the poison has been swallowed, the stomach should be washed out immediately and free lavage established. A suitable medium for the purpose is water at body temperature containing a 5% to 10% solution of sodium thiosulfate, or a mixture of the sulfates (ferrous and ferric) of iron followed by a solution of potassium carbonate to form prussian blue, which is inert. Sodium thiosulfate (10 to 50 ml. of 20% solution) or methylene blue (50 ml. of 1% solution) may be administered intravenously, provided there is time for either of these preparations to act. Ammonia inhalations, artificial respiration and oxygen, with or without carbon dioxide (7%), should be used to stimulate respiration. In desperate cases, a slow venous injection of five millilitres of a 25% solution of nikethamide has been recommended. Stimulation of the cardiac and respiratory centres may be effected by injections of lobeline and pentylenetetrazol (metrazol, cardiazol).

Strychnine and Strychnine-Yielding Plants.—The alkaloids strychnine and brucine, as well as the plants in which they are found, all act in the same manner, being highly poisonous and causing death after spasms of a severe character. Many vermin killers contain strychnine as their active ingredient.

Strychnine and all substances containing that alkaloid usually

produce their effects within 10 or 15 minutes. The patient complains of stiffness about the neck, and his aspect exhibits terror. There is an impression of impending calamity or death. Very speedily the head is jerked back, the limbs extended, the back arched (opisthotonos) so that the body may rest on the head and heels only. In a few moments these symptoms pass off, and there is complete relaxation of the spasm. The spasmodic condition speedily returns, and is brought about by the slightest touch or movement of the patient. Accessions and remissions of the tetanic state ensue rapidly till the patient succumbs, usually within half an hour of the administration of the poison.

The best treatment is to put the patient under the influence of chloroform and wash out the stomach with a solution of potassium permanganate in water, four grams in two gallons. To follow, medicinal charcoal in water is recommended, and this should be freely given and removed from time to time. Sodium amytal or phenobarbital sodium should be given intravenously. Only a quantity sufficient to put the patient to sleep or to stop convulsions, if present, should be given.

Nicotine.—The alkaloid nicotine is obtained from the plant *Nicotiana tabacum*, the common tobacco of commerce, and has a pungent, acrid taste. Its content in tobacco leaves varies from 0.6% to 6%. Poisoning may be caused by absorption through the skin, by inhalation or by ingestion. Industrial poisoning caused by commercial preparations, such as fertilizers and fumigants, has occurred.

Cases of acute poisoning are comparatively rare, but subacute and chronic symptoms may result from the immoderate use of tobacco. When nicotine is absorbed in poisonous dose, the outstanding symptoms are those of successive central and peripheral stimulation, nausea, sickness, tachycardia, cardiac oppression and irregularity and severe prostration and cardiovascular collapse may become manifest. Treatment consists of gastric lavage when the poison has been ingested. Strong coffee or a hypodermic injection of nikethamide should be given.

Opium.—In consequence of the extent to which opium, its preparations and its active alkaloid morphia are used for the relief of pain, poisoning by opium is of frequent occurrence. It is largely used by suicides, and children, being very susceptible to its influence, frequently die from misadventure after administration of an overdose of the drug. The ordinary preparations are the drug itself, which is the dried juice of the capsules of the poppy (*Papaver somniferum*), known in commerce as Turkish, Persian, Indian or European opium, and the tincture, commonly known as laudanum. The *British Pharmacopoeia* requires opium in its moist state, as imported, to contain not less than 9.5% of anhydrous morphine.

The treatment of opium poisoning is governed by the condition of each case in relation to the time of intake. It consists of free gastric lavage with warm water and then with two grams of potassium permanganate in two gallons of warm water. The use of medicinal charcoal is beneficial. In coma, the airway should be kept clear, the patient catheterized and artificial respiration and inhalations of oxygen, or of oxygen with 7% carbon dioxide, should be employed if thought necessary.

Heroin.—Heroin is an artificial derivative of morphine (diacetyl morphine hydrochloride) and is more toxic than morphine. It is no longer used medicinally in the U.S. and Great Britain. (See HEROIN.)

Belladonna.—The belladonna, or deadly nightshade, *Atropa belladonna*, contains an alkaloid, atropine, which is largely used by oculists to procure dilatation of the pupils of the eye. The brown or black berries of the plant have been eaten by children, who are attracted by their appearance. Besides dilatation of the pupils, belladonna produces rapid pulse, hot, dry, flushed skin with an eruption not unlike that of scarlatina, soreness of the throat with difficulty in swallowing, and intense thirst and delirium.

The treatment consists of gastric lavage with a solution of 1 in 5,000 of potassium permanganate. Excitement should be controlled by sedatives or mild hypnotics. Lumbar puncture may prove beneficial in certain cases.

Stramonium, hyoscyamus (henbane), hyoscyamine, hyoscine

and scopolamine all produce symptoms similar to atropine poisoning, the narcotic effects being more marked.

Aconite.—The ordinary aconite, wolfsbane or monkshood (*Aconitum napellus*), and an alkaloid extracted from it, aconitine, are perhaps the most deadly of known poisons. A dose of 0.004 g. of aconitine has proved fatal to man. The root of aconite has been eaten in mistake for that of horse-radish. All the preparations of aconite produce a peculiar burning, tingling and numbness of the parts to which they are applied. When given in large doses they produce violent vomiting, as a rule, more or less paralysis of motion and sensation and great depression of the heart, usually ending in death from syncope. Intelligence remains unaffected till almost the last.

The treatment consists of free gastric lavage with a solution composed of 12 g. of tannic acid in two gallons of warm water. Tannic acid (1.2 g. in 180 ml. of tepid water) should be given and followed by animal charcoal suspended in water. Cardiac and respiratory stimulants should be administered in accordance with clinical indications. Artificial respiration and oxygen inhalations may prove necessary.

Cocaine.—Cocaine is the active alkaloid of coca leaves—*Erythroxylum coca*—and is chemically methyl benzoylecgonine. The hydrochloric salt is the commonly used preparation. It is a powerful deliriant narcotic poison. If taken by the mouth, given hypodermically or otherwise absorbed, it may cause delirium and coma. Sometimes convulsions and sudden death occur. It acts on the heart and may cause fatal syncope. Cocaine is a dangerous drug of addiction.

Organic Compounds Used as Hypnotics.—These if taken in excessive doses act as poisons, and the symptom which attracts attention is the deep coma produced. Examples are: chloral, barbital and its derivatives, etc. Any hypnotic drug taken in excessive quantity will act as a coma-producing poison. See BARBITURATES.

GASEOUS POISONS AND WAR GASES

Carbon Monoxide.—Poisoning by carbon monoxide may occur from coal gas, water gas or from exposure to the suffocating fumes of fires, smoky grates and stoves; also from the fumes of gas heaters and internal-combustion engines.

The diagnosis may be made at once from the clinical symptoms of drowsiness, collapse and coma, and the cherry-red colour of the face, body and mucous membranes. Examination of the blood will make the diagnosis certain, since the presence of carboxyhemoglobin may be readily detected by the spectroscope.

The treatment consists in giving oxygen with 7% carbon dioxide freely, and employing artificial respiration if necessary. The use of carbon dioxide is important since it stimulates breathing and breaks down the carbon monoxide-hemoglobin molecule. The body warmth must be maintained. This is important since carbon monoxide disturbs the heat-regulating centre with reduction in the processes of oxidation. Stimulants administered hypodermically will also prove beneficial.

Carbon Dioxide, or Carbonic Acid.—This occurs in coal mines from chokedamp or afterdamp. Cellars of houses, wells, brewers' vats, lime kilns, etc., frequently contain large quantities of carbonic acid gas. The treatment consists in fresh air, rest, oxygen, artificial respiration if necessary, and employment of warmth and stimulants.

Hydrogen Sulfide, or Sulfureted Hydrogen.—This occurs from contamination of the air with sewer gas, and from the gases evolved when iron slag becomes moistened with water. The gas is frequently produced in various chemical processes. The treatment consists in giving the patient plenty of fresh air. Oxygen and stimulant treatment must be used.

War Gases.—Despite the fact that a mixture of gases may be employed, it is customary to classify war gases into four groups: (1) gases producing irritation of the lungs (choking gases); (2) gases producing irritation of the nose (nasal irritants); (3) gases producing irritation of the eyes (lachrymators); and (4) gases producing irritation of the skin (vesicants).

Group 1 includes phosgene, diphosgene, chlorine and chloro-

picrin. All these gases when inhaled produce rapid bronchial and pulmonary irritation which may lead to death within a day or two from cardiac failure brought about by inflammatory edema. A later fatal complication results from bronchopneumonia.

Group 2 includes smokes which are liberated from the highly toxic arsenical compounds diphenylamine chlorarsine or DM, diphenyl chlorarsine or DA, and diphenyl cyanoarsine or DC. These are capable of causing profound sensory disturbance which in warfare diminishes physical capacity and undermines morale.

Group 3 includes ethyl iodacetate or KSK, bromobenzyl cyanide or BBC, and chloroacetophenone or CAP. The vapours of these substances produce transient irritating effects on the eyes, which water copiously. If the liquids from which these vapours arise are brought into contact with the eyes severe and permanent damage may result.

Group 4 includes bis β -chloroethylsulfide or mustard gas, and β -chlorovinylchlorarsine or lewisite. These liquids give off toxic vapours which affect the lung, eye and skin on account of their irritant action. In their liquid form such fluids cause severe burning with destruction of the tissue with which they are brought into contact. Their power of penetration of the skin is very considerable since they are capable of producing lipid solubility. Mustard gas has a delayed action and on this account serious delay in treatment may occur. Lewisite acts much more rapidly. The arsenic content of lewisite when absorbed by the skin may produce tissue damage in the secretory and urinary systems. See CHEMICAL WARFARE.

(W. H. Wl.; Jo. Gr.)

POISONOUS FOODS

The term food poisoning is generally applied to a group of illnesses occurring after the ingestion of food containing a variety of agents such as chemical, plant and animal poisons as well as certain microbes or their poisons. Ptomaine poisoning is a misnomer since it does not represent a defined chemical entity capable of causing food poisoning.

Toxic chemicals may find their way into food by malicious intent. Chemicals such as insecticides, rodenticides and herbicides may cause poisoning if allowed to remain in toxic doses on food when eaten. Chemicals that are added to foods to improve quality may be toxic under certain circumstances and not recognized immediately. For example, flour bleached with gaseous nitrogen trichloride (agene) caused convulsions when fed to dogs. As a result, use of agene as a bleaching agent for flour was prohibited.

Plants such as poisonous mushrooms, snakeroot, water hemlock, rhubarb leaves, rye infected with the ergot fungus, seeds of the unripe ackee and tung nuts are poisonous when eaten.

Shellfish, eaten raw or cooked, may be poisonous after ingesting certain toxic plankton. Several tropical fish have been shown to be toxic. Organs such as the liver and ovaries of globe fish and certain sharks may be toxic. The flesh of the Moray eel is also poisonous when eaten.

Microbial food poisoning is of two types: (1) that in which the poison (or toxin) is produced in a food by the growth of microorganisms, and the poison (not the microorganism) gives rise to illness, and (2) that in which living organisms are present in a food in numbers large enough to cause illness. The mechanism of illness caused by living organisms is not understood.

Botulism, caused by a toxin produced by *Clostridium botulinum*, is the most serious type of food poisoning, fatal in approximately 65% of the cases in the United States. It leads to muscle paralysis, and death is due to respiratory failure. The microorganism causing botulism grows in the soil and produces heat-resistant spores that grow in the absence of air in low-acid, underprocessed home-canned foods. Boiling destroys botulinum toxin.

The poison produced by the growth of staphylococci in foods causes severe gastrointestinal disturbances usually within 2½ to 3 hours after ingestion of the food. These bacteria are commonly found in the throat and on the skin of man, where they may cause pimples and abscesses. Staphylococci grow in many foods with a high salt and sugar content, and control of staphylococcal food poisoning depends on adequate refrigeration of perishable foods. The food poisoning toxin of staphylococci is resistant to boiling.

Living microorganisms that cause food poisoning include *Salmonella*, which produce infection with gastrointestinal disturbances usually from seven hours to one day or more following the ingestion of a meal containing them. *Salmonella* grow in the intestines of man and animals and are sometimes found in raw meat and poultry products and food subject to fecal contamination. These microorganisms are readily destroyed at pasteurization temperatures.

Other living microorganisms causing illness are certain types of cocci and bacilli, which produce mild illness characterized principally by vomiting and diarrhea 6 to 15 hours after ingestion of food containing large numbers of them (alpha-type streptococcus, *Clostridium perfringens* and *Bacillus cereus*).

POISON HEMLOCK, a poisonous Eurasian plant (*Conium maculatum*) of the carrot family (Umbelliferae). It is a branching biennial herb from 3 to 10 ft. tall, with parsleylike, malodorous leaves, small white flowers in compound umbels, and conspicuously purple-blotched stems and leaf stalks. It has become widely naturalized in moist areas in North and South America and is not uncommon in gardens, where it has even been grown as an herbaceous hedge under the name of California fern. In the Pacific coast states poison hemlock may form dense thickets in wet roadside ditches, the plants reaching 10 ft. or more in height. The leaves are reported to cause dermatitis. All parts of the plant contain the toxic principles coniine, conhydrine, methylconiine and coniceine and are poisonous to eat. The leaves, sometimes mistaken for parsley, are most toxic when the plant is in flower; the roots are least toxic in the spring. Chickens have been killed from eating the seeds. Death occurs in man and animals from respiratory paralysis and differs from water hemlock (*g.v.*) poisoning in that no convulsions occur and the mind reportedly remains clear until the end. Poison hemlock is one of the historically famous plant poisons, presumably the one administered by the Greeks to Socrates and other state prisoners. From Plato's description of the effect of the poison drink on Socrates (*Phaedo*) there is little question of its identity. See also ALKALOIDS; POISONOUS PLANTS.

(Md. E. M.)

POISON IVY, the name commonly applied to several, mostly white-fruited, trifoliate species of woody vines or shrubs of the genus *Toxicodendron* of the cashew or sumac family (Anacardiaceae), native to North America. The forms with bushy habit and lobed leaflets are often called poison oak, especially in the western United States. The common poison ivy (*Toxicodendron radicans*), the most widespread species, abundant in eastern North America and less common westward, is a variable species with a bushy or climbing habit and leaves with three leaflets which may be smooth and glossy or hairy, entire, toothed or lobed. Many of these not too constant variations have been designated as separate species or varieties. The commoner of these forms with their ranges are: *T. quercifolium*, with deeply lobed leaflets, Maryland to Texas; *T. radicans rydbergi*, with thicker leaves, Great Plains

to Rocky mountains; and *T. diversilobum*, with leaflets mostly scalloped on the margin, Pacific coast. The poison sumac (*T. vernix*), native in swamps from Quebec to Minnesota and south to Texas and Florida, is a tall bush or small tree with pinnately compound leaves with 7 to 13 entire leaflets and drooping, axillary clusters of persisting white fruits. (The common nonpoisonous sumacs of the genus *Rhus* [see SUMAC] have distinctive reddish fruit.)

All species of *Toxicodendron* are poisonous to touch, producing in many persons a severe inflammation of the skin, or dermatitis (see below). The toxic principle, urushiol, is produced in the resinous juice of the resin ducts of the leaves, flowers, fruits and bark of stems and roots but not in the pollen grains. Being almost nonvolatile, the urushiol may be carried from the plant on clothing, shoes, tools, soil, by animals, by smoke from burning plants, to persons who never go near the poison ivy plants. Poisoning may occur if clothing is worn a year after contact with poison ivy. (W. C. M.)

Poison Ivy Dermatitis.—The juice of all portions of the poisonous plants discussed above is not irritating or poisonous on first exposure; but after one or more contacts, most persons become sensitized or allergic and will react to the juice with a rash. The sap must get on the skin for the dermatitis to develop. The hands and clothing may transfer sap to other portions of the body not directly exposed. The rash may develop as early as 6 to 12 hours or as late as a week or more after exposure; most commonly it appears within 24 to 48 hours. No one is born with sensitivity; it is generally acquired during childhood and tends to be highest at this time, but over the years it declines despite exposure to the plants. Once sensitivity is lost, a solid immunity remains and the person cannot easily be made sensitive again. The plants are so common and the juices such highly potent sensitizers that over three-fourths of the American population acquires poison ivy dermatitis at some time.

The severity of the rash varies directly with the quantity of sap deposited on the skin and with the person's inherent degree of sensitivity. Sensitivity may be so great that the sap diluted 50,000,000 times will still induce a rash. Even a mildly sensitive person can develop an intense eruption following a high degree of exposure, but the rash heals in a week or less as contrasted with two or three weeks for the highly sensitized.

A moderate degree of immunity can be established, plant extracts given orally (very small doses at first, increased daily over the next few months) being effective. Although complete desensitization is impossible, and skin rash may occur as a side effect, this prophylactic treatment is justified for the highly sensitive because it lessens the intensity and duration of the rash.

Anointing the skin before exposure with "barrier" or detoxifying creams is generally useless, and washing the skin with solvents, soaps or detoxicants is ineffective unless performed within a few minutes after contact. ACTH and cortisone-like drugs, by mouth or injection, promptly control the rash; this is the only known treatment that has a clear-cut beneficial effect. The great majority of popular and folk remedies for local application are without benefit and many are harmful. Bland compresses and soothing lotions do not restrain the rash, but provide comfort and maintain hygiene until the skin recovers spontaneously. See also POISONOUS PLANTS. (A. M. K.)

POISONOUS PLANTS are plants that produce adverse physical effects, and sometimes death, when eaten or touched by man or animals. Most plant species are harmless; a few are poisonous under ordinary conditions, others are poisonous under special conditions. Toxic materials are often very strictly localized in the plant. Opium and its related drugs come from the milky latex of the opium poppy (*Papaver somniferum*) but are absent from the seeds, which may be eaten for food. In the water hemlock (*Cicuta maculata*) the root and fruit are poisonous, whereas in corn cockle (*Agrostemma*) the poisonous glycoside is confined to the seeds. The leaf blades of rhubarb (*Rheum raphanistrum*) are highly poisonous but the leaf stalks are nonpoisonous. Some plants are harmless when eaten green and fresh but poisonous when wilted or dried. Others are poisonous when raw

but nonpoisonous when cooked. While it is not possible to classify poisonous plants by the toxic ingredient, knowledge of the type of toxic substance is helpful in diagnosing symptoms and treatment.

Types of Toxic Substance.—In general the poisonous character of a plant is due to the presence of one of four groups of organic compounds: an alkaloid, a glycoside, a resin or an organic acid.

Alkaloids.—An alkaloid is a nitrogen-containing organic base; it is colourless, odourless, nearly insoluble in water and very bitter. Except for the fungus ergot (*Claviceps purpurea*), a parasite on rye, and poisonous mushrooms, the sources of all alkaloids are flowering plants. Notable among alkaloids are the opiates and codeines of the opium poppy, the atropine-nicotine groups in the Solanaceae (the nightshade family) and the curines (curare poisons) in tropical members of several families. (See ALKALOIDS.)

Glycosides.—A glycoside (glucoside, in part) is a complex carbohydrate which on hydrolysis and in the presence of amino acids or enzymes produces one or more simple sugars and a nonsugar end product called aglycon. These carbohydrates are water-soluble, bitter, often odour producing and may be coloured or colourless. Three primary groups of plant glycosides yielding toxic products on hydrolysis are: (1) cyanogenetic glycosides, in which the poisonous by-product is hydrocyanic acid or prussic acid and found in species of *Sorghum*, *Prunus* (wild cherries, almonds) and *Linum* (flax); (2) saponin glycosides, produced in species of *Agrostemma* (cockle), *Digitalis* (foxglove), *Actinea* (rubberweed); and (3) solanine glycosides, produced in members of the nightshade family, especially berries of *Solanum*. (See also GLYCOSIDES. NATURAL.)

Resins.—The toxic resins or resinoids occur in poisonous members of the heath family (Ericaceae), water hemlock (*Cicuta*) of the carrot family, and in the milkweeds (Asclepiadaceae). For the most part they are an insoluble gummy material of complex organic structure, localized in resin- or latex-containing ducts.

Organic Acids.—Only a few of the organic acids commonly found in plants are toxic in the amount or in the form in which they occur naturally. The family of nettles (Urticaceae) owes its reputation to the irritant properties of formic acid, which is borne in the hairs of the leaves and stems of most of the species. The toxic properties of *Prunus* species (leaves, bark, and seeds), as mentioned earlier, depend on the generation of hydrocyanic acid. Oxalic acid, occurring usually as oxalates, is present in considerable amounts in the leaves of rhubarb, in *Oxalis* and *Rumex* species, and in rhizomes of Jack-in-the-pulpit.

Types of Physiological Action.—Poisonous plants may be grouped according to the physiological actions they produce. These groups and some plant examples include: (1) blood poisons: species of *Prunus*, seeds of castor bean (*Ricinus*) and rosary pea (*Abrus*); (2) nerve poisons: poisonous mushrooms, Jimson weed (*Datura*) and henbane (*Hyoscyamus*); (3) neuromuscular poisons: ergot, foxglove and arrow poisons (curare); (4) muscular poisons: false hellebore (*Veratrum*); and (5) skin irritants or dermatitis-producing plants: poison ivy (*Toxicodendron radicans*), parsnip (*Pastinaca*), mustard (*Brassica*), poisonwood (*Metopium*) and snow-on-the-mountain (*Euphorbia marginata*).

Plants Poisonous on Contact.—Skin poisoning, or dermatitis, is the typical plant contact poisoning. This type of reaction varies from a minor or temporary irritation to an itching rash or a painful inflammation with watery blisters that may last for days or weeks. In most plants that produce this reaction the toxic ingredient is concentrated in a resinous or milky juice. The severity of the symptoms varies with the susceptibility of the individual and with the amount of contact with the toxic agent. Some persons may be immune to poisoning by one species but susceptible to that by another; immunity may be complete or only partial; it may be lost or acquired over the years.

Plants noted for dermatitis-producing qualities include:

Cashew Family (Anacardiaceae).—Poison ivy and poison oak (*Toxicodendron* species), poison sumac and poison dogwood (*Toxicodendron vernix*) and Japanese lacquer tree (*Toxicodendron verniciflua*) are native to temperate regions and may be distinguished from nonpoisonous sumacs by the white (not red) fruits.

POISONOUS PLANTS

PLATE I

Ohio buckeye (*Aesculus glabra*), which some authorities name *A. sylvatica*. The seeds and leaves that are poisonous to livestock.

May apple (*Podophyllum peltatum*), showing the flower and the unripe berry. The berry is moderately poisonous at this stage but edible when fully ripe; the roots are poisonous.

Allamanda (*Allamanda cathartica*), of the dogbane family, many members of which are poisonous.

Bittersweet, or false bittersweet (*Celastrus scandens*), a decorative vine. The scarlet pulp of the fruit is moderately toxic.

Mistletoe (*Phoradendron flavescens*), whose whitish berries are poisonous.

Common sneezeweed (*Helenium autumnale*), a powerful respiratory and contact irritant.

POISONOUS PLANTS

Croton (*Codiaeum*), one of the Euphorbiaceae, many members of which have a poisonous milky juice

Poison ivy (*Toxicodendron radicans*), a skin irritant. The whitish berries and three-part leaves are distinctive features

Jack-in-the-pulpit (*Arisaema triphyllum*) Inflames the membranes of the mouth and throat if eaten raw

Jimson weed (*Datura stramonium*). The seed pods and seeds are a dangerous nerve poison

Cardinal flower (*Lobelia cardinalis*), suspected of being poisonous to livestock

Pokeweed (*Phytolacca americana*). The seeds and roots are poisonous

In poison ivy and its relatives the leaves are of three leaflets (never five), are usually coarsely toothed, and are glossy on the upper surface when young. Poison sumac leaves have 7 to 15 leaflets, whose margins are never toothed, and the hairless leaf stalk is usually reddish. The poisonwood of southeastern United States and the West Indies (*Metopium toxiferum*) resembles the more northern poison sumac.

Spurge Family (Euphorbiaceae).—The milky sap of the following plants produces varying degrees of dermatitis in susceptible individuals: many species of spurge (*Euphorbia*), including the cultivated ornamental snow-on-the-mountain (*E. marginata*), an annual whose leaves are margined white; and the manchineel tree (*Hippomane mancinella*) of the American tropics.

Nettles.—Some plants produce a nonpoisonous but very irritating stinging rash of short duration, termed an urtication. These plants bear sharp, brittle, glandular hairs that are hollow and filled with an irritating watery material which enters the skin when punctured by the hair. Included among these are the common nettle (*Urtica gracilis*, *U. urens*), the stinging nettle (*U. dioica*) and the wood nettle (*Laportea canadensis*).

Others.—Miscellaneous kinds of dermatitis-producing plants include the wild parsnip (*Pastinaca sativa*), which has coarse, celery-like foliage and bright yellow flowers; certain primroses (especially *Primula obconica*, *P. malacoides* and *P. sinensis*); several kinds of lady'slipper orchids (*Cypripedium acaule*, *C. calceolus*, *C. reginae* and *C. parviflorum*); several species of milkweed (*Asclepias*) and osage orange (*Maclura pomifera*). Foods made of buckwheat flower (*Fagopyrum esculentum*) produce dermatitis in some individuals.

Plants Poisonous on Ingestion.—Most plants that are poisonous when eaten are not tasty or likely to be eaten, except by children. Unfortunately, the quantity of poison fatal for a child is only a fraction of that fatal for an adult. These plants may be conveniently grouped according to the plant part that carries the toxic substance.

Roots.—Roots of the following may cause serious or fatal poisoning when eaten: (1) Jack-in-the-pulpit (*Arisaema*); the tuberous rhizome is rich in calcium oxalate crystals and produces inflammation of the membranes of the mouth and the throat when eaten raw; boiling in water dissolves the crystals and renders the tubers edible. (2) Death camass (*Zigadenus*); the bulbs are rich in the highly toxic alkaloid zygadenine, and sometimes are eaten by children. (3) Star-of-Bethlehem (*Ornithogalum*); all parts of the plant are poisonous, and the bulbs especially should not be kept where children have access to them. (4) Amaryllis and relatives (*Hippeastrum*, *Zephyranthes*, *Crinum* and *Hymenocallis*) produce bulbs containing poisonous alkaloids; they also should not be kept where children may obtain them. (5) Water hemlock (*Cicuta*) and poison hemlock (*Conium maculatum*) contain a highly toxic yellowish resin in the roots; fatal poisoning may result from eating them. These plants belong to the carrot family, produce flat-topped clusters of white flowers and grow in wet lowlands or along streams. (6) Potato (*Solanum tuberosum*) is poisonous when the tuber grows at the surface of the soil and becomes green through exposure to the sun; "greened" potato tubers should never be eaten.

Shoots and Foliage.—Shoots and foliage of the following may cause poisoning: (1) Pokeweed (*Phytolacca americana*); young shoots cooked as a potherb are edible, but the water should be poured off and replaced with fresh to remove the water-soluble toxic material. (2) Poison hemlock (*Conium maculatum*); children have been fatally poisoned by eating small quantities of foliage or stalk. (3) Fool's-parsley (*Aethusa cynapium*), an annual with parsleylike leaves, is sometimes eaten in error for garden parsley, with fatal results; the leaves are never mosslike or curly. (4) Tansy (*Tanacetum vulgare*); a tea made from the foliage is poisonous, and overdoses have been fatal.

Flowers.—Flowers of poisonous plants are rarely eaten deliberately. However, children eating flowers or buds of tiger lily (*Lilium tigrinum*) have been poisoned with near-fatal results. The anthers contain an alkaloid not known in other lily species.

Fruits and Seeds.—Fruits and seeds of poisonous plants are

occasionally eaten with fatal or near-fatal results, especially by children. The following, while by no means complete, is a listing of common poisonous fruits to be avoided: (1) Baneberry (*Actaea*, a woodland perennial herb bearing bright red or white berries about half an inch long; the berries are not tasty and are moderately toxic. (2) Belladonna (*Atropa belladonna*), a perennial producing bell-shaped dull-purplish flowers and black berries with violet juice; the toxic alkaloid hyoscyamine is present in all parts of the plant. (3) Bittersweet (*Celastrus*), a woody vine producing orange-red berrylike fruits in autumn, prized for decorative uses; the outer scarlet pulp contains a moderately toxic, sweetish but disagreeable-tasting alkaloid, celastrol. (4) Black nightshade, or garden huckleberry (*Solanum nigrum*), an annual herb with drooping clusters of black, globose berries about three-quarters of an inch in diameter; the unripe berries are poisonous, but the ripe fruit is edible, and cooking or boiling destroys remnants of the poisonous material. (5) Blue cohosh (*Caulophyllum thalictroides*), a low, perennial herb of moist, rich, woodland areas, produces stiffly erect stalks of pea-sized dark-blue "berries" above the foliage; the very bitter berries contain a poisonous alkaloid. (6) Chinaberry (*Melia azedarach*) is a tree of warm temperate regions producing panicles of fragrant purple flowers followed by pale yellow, berrylike drupes about half an inch across; the fleshy pulp of the fruit contains a paralyzing nerve poison. Coyotillo (*Karwinskia humboldtiana*), a rangeland shrub with oval, brownish-black berries about half an inch long; the leaves and fruit pulp are less toxic than the seeds. (7) Daphne (*Daphne*), a low shrub producing fragrant, showy flowers in spring, followed by orange or red berrylike drupes about one-fourth inch long; a small number of the berries may cause fatal poisoning in children. (8) English ivy (*Hedera helix*), an evergreen vine, produces umbels of black or orange poisonous berries sometimes eaten by children. (9) Euonymus, burning bush, wahoo (*Euonymus atropurpureus*), a shrub with reddish capsules whose few seeds are each covered by a bright, orange-red, fleshy aril; the fruits and seeds are moderately poisonous when eaten. (10) European bittersweet, or blue nightshade (*Solanum dulcamara*), is a clambering vine, herbaceous becoming woody, with clusters of small white flowers followed by attractive bright red berries about one-third inch across; both leaves and bark have a strong, disagreeable odour, and the berries, moderately poisonous if eaten in quantity, contain the alkaloidal glucoside solanine. (11) Henbane (*Hyoscyamus niger*), a much-branched, clammy-hairy herb with a fetid odour when crushed, produces yellowish, funnel-shaped flowers with purple veins, followed by a seed pod enclosed in a persistent calyx; children eating seed pods or seeds have been poisoned by the alkaloid hyoscyamine. (12) Holly (*Ilex*) produces attractive red, yellow or black berries that are somewhat (but not highly) poisonous and should not be eaten. (13) Jerusalem cherry (*Solanum pseudo-capsicum*) is grown as an ornamental pot plant and prized for its showy globose orange berries nearly an inch across; the fruits contain toxic quantities of several poisonous materials and should never be eaten. (14) Jimson weed (*Datura stramonium*), an annual weed with showy white or purplish funnel-form flowers, three to six inches long, followed by globose prickly pods about one inch across; the soft, unripe seed pods are poisonous when eaten, and the seeds are increasingly toxic. (15) Manchineel tree (*Hippomane mancinella*), a small subtropical tree of the Euphorbiaceae, produces milky sap, spikes of small greenish flowers, followed by berrylike drupes about 1½ in. across; persons eating the fruits in the belief that they were edible have been fatally poisoned. (16) Matrimony vine (*Lycium halimifolium*), a woody clambering vine of the Solanaceae, somewhat thorny, produces small white funnel-form flowers in leaf axils, followed by bright orange-red berries about one-third inch across; the berries are moderately toxic and contain a hyoscyaminelike alkaloid. (17) May apple (*Podophyllum*) is a perennial herb of rich, open woodlands or pastures, producing large, umbrella-shaped leaves, beneath which appear one or two nodding white flowers an inch across, followed by a yellow or reddish berry about 1½ in. long; when fully ripe the berries are edible, but when hard, green and immature, they contain highly

toxic quantities of a purgative resin, podophyllin. (18) Mistletoe (*Phoradendron*, *Viscum album*), an evergreen parasitic plant growing on trees, produces decorative whitish berries that are reported to have been fatally poisonous when eaten by children. (19) Pokeweed (*Phytolacca americana*), a coarse tall perennial herb with reddish-purple stems and glossy green leaves, produces dense terminal racemes of small white flowers followed by crimson-juiced, glossy black berries; the berry pulp is believed to be non-poisonous, but the black glossy seeds contain toxic quantities of saponins and alkaloids. (20) Privet (*Ligustrum*), a common shrub often grown for hedges, has small racemes of white flowers followed by bluish-black berries about one-fourth inch across; the berries are reported to be fatally toxic to children.

Mushrooms.—Mushroom poisoning commonly is fatal to man. Many mushrooms contain toxic alkaloids (muscarine, agaricine, phalline) and identification of poisonous types from the non-poisonous should be made only by an expert. The edible mushroom of commerce is *Agaricus campestris*, but some species of the genus are poisonous. The designation of poisonous types as toadstools and the nonpoisonous as mushrooms is common but meaningless. (See also MUSHROOM.)

Stock-Poisoning Plants.—These are of many kinds and vary with the different countries and regions. Of particular importance in North America are cocklebur, black nightshade, water hemlock, death camass, milkweed, sneezeweed, Jimson weed and the locoweeds. The symptoms of stock poisoning are varied, rendering diagnosis difficult.

Arrow Poisons.—These, concocted from the juices and resins of a variety of plants, are of importance to aborigines of many areas, particularly of the tropics, for shooting of animals and fish and in warfare. In the 20th century the active ingredients have proved to be important in medicine. All South American Indian arrow poisons are grouped under the name curare and may be classified as neuromuscular toxins. From them the alkaloid curine has been isolated. Derivatives of this arrow poison have proved useful in anesthetics to induce muscle relaxation. The material as used by the Indians is a dark gummy mass. Small quantities carried on the tip of an arrow to the flesh of man or animal induce paralysis of the voluntary muscles followed by stupor and death due to failure of respiratory muscles.

Crude arrow-poisoning material was first introduced to modern civilization in 1595, when Sir Walter Raleigh brought a tiny vial of it to England. From that time onward reports of its preparation, use and efficacy became a mixture of folklore and fact. The aboriginal use of the potion was accurately observed in 1800 and reported in 1807 by Humboldt. Later the German botanist R. H. Schomburgk witnessed its preparation by Indians in British Guiana and reported it in detail in 1844. Preparation of the poison was a closely guarded secret and ritual, handed down from father to son, and today, through the influence of firearms, it is rapidly becoming a lost art in much of South America.

Detailed information on the plants used and procedures for making the poison were learned from the Tecuna Indians of Brazil by B. A. Krukoff, who reported on them in 1937. Bundles of stems of the plants *Strychnos castelnaei* and *Chondodendron tomentosum* were gathered and brought from the forest. The outer bark was peeled or scraped from the stems, packed into a bundle, wrapped in palm leaves and allowed to set over night. It was then suspended over an empty clay pot and opened at the top. About two quarts of cold water was poured very slowly over the bark and collected in the pot. This extract was transferred to a larger pot and brought to boil over a steady fire. Several collections of the cold-water extract were similarly prepared and added to the concoction, which was kept boiling for at least eight hours, when it was reduced to about one-eighth its original volume. On the third day the extract was triple-strained through a palm spathe and again boiled gently for several more hours. To this a decoction of macerated roots of other plants (e.g., species of *Piper*) was added, boiled and strained. During the process an extract of stems and leaves of *Dieffenbachia insignis* and of tubers of *Aristolochia* was added and the whole boiled down to a thick,

gluelike sirup of dark chocolate colour. When cool its potency was tested on some bird or animal. The material was stored in covered pots, gourds or bamboo tubes and kept as dry and cool as possible.

The identity of all the plants used in the preparation of curare remains incomplete, but leaves and stems of the following plants are known to be used: *Chondodendron tomentosum* (Menispermaceae), *Strophanthus* (Apocynaceae), *Strychnos* (Loganiaceae) and *Cocculus* (Menispermaceae).

POISONS, AFFAIR OF THE, one of the most sensational criminal cases of 17th-century France. Brought to light in 1679, three years after the execution of the marquise de Brinvilliers (q.v.), it revealed that nobles, prosperous bourgeois and the common people alike had been resorting secretly to women fortune-tellers—at that time very numerous in Paris—for drugs and poisons, for black masses (incantations of black magic) and for other criminal purposes. The inquiry into the affair was entrusted by Louis XIV to the lieutenant of police, Nicolas de La Reynie, whose diligent investigation took three years. A special tribunal for the trial of the accused, known as the *Chambre ardente*, was set up in April 1679: it held 210 sessions at the Arsenal in Paris, issued 319 writs of arrest (218 of which were carried out), conducted 865 interrogations and sentenced 36 persons to death (34 of whom were actually executed), 4 to labour in the galleys and 34 to banishment or fines, while 30 persons were acquitted. The poisoner called La Voisin (Catherine Deshayes, Madame Monvoisin) was burned in the Place de Grève on Feb. 22, 1680.

Persons who were compromised included the comtesse de Soissons (Olympe Mancini, a niece of the late Cardinal Mazarin), whose flight from France was abetted by the king; the duchesse de Bouillon (Marie Anne Mancini, also a niece of Mazarin's); the comtesse de Gramont (Marie Christine de Noailles); the vicomtesse de Polignac (Jacqueline de Grimoard de Beauvoir); the princesse de Tingry (Marie Charlotte de Luxembourg); the maréchale de La Ferté (Madeleine d'Angennes); the maréchal duc de Luxembourg, who was found innocent; the duchesse de Vivonne (Antoinette de Mesmes, sister-in-law of the marquise de Montespan); and the marquise de Montespan (q.v.) herself. La Voisin under interrogation had always denied any dealings with Madame de Montespan; but after she was executed her daughter and her accomplices accused Madame de Montespan of having been one of La Voisin's clients since 1667, of having used philtres and "love powders" to win the king's love and to supplant the duchesse de La Vallière, of having taken part in black masses and of having tried to poison her rival Mademoiselle de Fontanges (Marie Angélique Scorraille de Roussilles) and Louis XIV himself. When her name was mentioned the king suspended the public proceedings, but ordered that the inquiry should go on. Thus the chief offenders, who had managed by their statements to transform a criminal trial into an affair of state, escaped the stake or the gallows and ended their lives in various provincial prisons. Madame de Montespan certainly had dealings with La Voisin and had recourse to magic in order to win and keep the king's love, but the charges concerning black masses and attempted poisonings have not been proved against her. Her accusers cannot be taken at their word in the absence of independent evidence.

POISSON, SIMÉON DENIS (1781–1840), French mathematician, known for his work on definite integrals, electromagnetic theory and probability, was born at Pithiviers in the *département* of Loiret on June 21, 1781. He studied medicine but gave it up in favour of mathematics. In 1798 he entered the *École Polytechnique* at Paris, where he attracted the notice of Lagrange and Laplace. Until his death on April 25, 1840, he was almost entirely occupied in mathematical research and in teaching. He was made deputy professor at the *École Polytechnique* in 1802, and full professor in succession to Fourier in 1806. In 1808 he became astronomer at the Bureau des Longitudes; and when the *Faculté des Sciences* was instituted in 1809 he was appointed professor of pure mechanics. His most important work was on the application of mathematics to physics, and in particular to electrostatics and magnetism. In the field of pure mathematics, his most important works were his series of memoirs on definite integrals, and his discussion of Fourier's series, which paved the way for the classical researches of Dirichlet and Riemann on the same subject. His studies on probability and the Poisson distribution law are of great importance.

Besides his many memoirs, Poisson published a number of treatises: *Traité de mécanique*, two volumes (1811 and 1833), which was long a standard work; *Théorie nouvelle de l'action capillaire* (1831); *Théorie mathématique de la chaleur* (1835); *Supplément to the same* (1837); *Recherches sur la probabilité des jugements*, etc. (1837). See also references under "Poisson, Siméon Denis" in the Index. (O. Oe.)

POITIERS, COUNTS OF, one of the great feudal dynasties of medieval France. The counts of Poitiers in Merovingian times were dim and insignificant officials administering Poitou (*q.v.*); the countships gradually became hereditary in the Carolingian period. Ramnulf I, who appears as count of Poitiers under King Pepin II of Aquitaine in 840, fought well against the Northmen or Normans and was killed in battle at Brissarthe in 866. His son Ramnulf II, in possession of the countship from 878, gave proof of his ambitions by annexing Saintonge. After his death (890 or 891) his house suffered a setback, during which Poitiers was ruled by the counts of Angoulême; but his bastard son, Eble Manzer, not only recovered the countship of Poitiers in 902 but also held Limousin and probably Auvergne as well from 927. Eble Manzer's son William I Towhead, count of Poitiers from 940 at the latest, finally styled himself duke of Aquitaine (*q.v.*; as duke he is reckoned as William III); and his son William II and IV Fier-à-Bras or Strong-in-the-Arm consolidated the position (963–c. 994), so that the name William, or Guilhem in the language of southern France, became traditional in the house. His son William III and V the Great (d. 1030) extended the dynasty's power, being recognized as suzerain in distant Velay and Périgord. By the second of his three marriages—to Brisca, sister of the Gascon duke Sancho William—he paved the way for a reconstitution of the Aquitania of Roman times. On good terms with England, Castile, and Navarre, he cared little for the French king's overlordship. He founded the abbey of Maillezais, where he was entombed.

William the Great's sons, William IV and VI the Fat (d. 1038), Eudes or Odo (d. 1039), William V and VII Aigret (called Peter before assuming the name of William; d. 1058), lost Loudun, Mirebeau, and Saintes to the counts of Anjou, but Aigret's brother and successor, Guy Geoffrey (William VI and VIII; d. 1086), brilliantly restored the dynasty's fortunes. He had already won Gascony during Aigret's lifetime; and he fought successfully against the Angevins and the counts of Toulouse and campaigned against the Muslims in Spain. He founded the great abbey of Montierneuf, in which he was buried. His son, the aggressive William VII and IX (d. 1126), is chiefly remembered as a troubadour of genius and as the patron of a flourishing literary and artistic civilization; but the troubadour's son William VIII and X the Toulousain (d. 1137) was preoccupied by local disputes with refractory lords and also quarreled with St. Bernard of Clairvaux. Through the successive marriages of this William's daughter Aliénor (see ELEANOR of Aquitaine) the countship passed first to

the Capetians of France, then to the Angevins of England, thus losing its individuality sometime before France's recovery of Poitou in the 13th century. (Re. C.)

POITIERS, a town of west-central France, capital of the former province of Poitou (*q.v.*) and of the modern *département* of Vienne, located 290 km. (180 mi.) SW of Paris. It commands the so-called gate of Poitou, a 44-mi.-wide gap between the Massif Armoricain (Armorican Massif) and the Massif Central, facilitating communication between northern and southern Europe. Poitiers occupies the slopes of a protuberance between the valley of the Clain River and that of its affluent the Boivre, a position which is suitable for defense and which explains much of the town's history. It is the seat of a bishopric. Pop. (1962) 59,799.

The streets are mostly narrow and tortuous, except for the modern Rue Victor Hugo (1869), which runs straight from the *préfecture* in the Place Aristide-Briand eastward to the *hôtel de ville* in the Place Maréchal Leclerc. The ring of boulevards surrounding the town follows the line of the medieval fortifications. Suburbs (*jaubourgs*) have sprung up along the outskirts of the town.

In Poitiers is the oldest building of Christian Gaul, the baptistery of Saint-Jean (4th and 7th centuries) just south of the cathedral. There are many beautiful Romanesque churches including the 11th–12th-century Notre-Dame-la-Grande; the church of St. Radegunda (d. 587), wife of the Frankish king Clotaire I, which contains her tomb, an object of pilgrimage; and that of St. Hilary (Saint-Hilaire-le-Grand; fl. c. 315–367), a native of Poitiers and its first known bishop, which was built over his tomb in the 11th–12th centuries in an unusual plan, its chief architect being the Anglo-Norman Gautier Coorland. The cathedral of Saint-Pierre, in the local Angevin style associated with Gothic, was begun in the mid-12th century and finished toward 1300. Its great Crucifixion window was the gift of Henry II of England (1133–89) and his queen, Eleanor (Aliénor) of Aquitaine (c. 1122–1204). A notable secular building is the *palais de justice* (formerly the palace of the dukes of Aquitaine, who were also counts of Poitou), incorporating Eleanor's so-called King's Hall. Poitiers has a university dating from 1432 and several professional and technical schools, including a *conservatoire* of music and a training institution for the deaf and dumb. There are four museums.

Poitiers had close ties with England, not only through Eleanor of Aquitaine but also through her son by Henry II, Richard I Coeur de Lion, who spent more time there than in London; and through Sir John Chandos, seneschal of Poitou (1360–72). Great numbers of Irish (who had their own college) and even more of Scots attended the university from the 15th to the 17th century; many of them settled in Poitiers.

Poitiers is an important railway junction on the Paris–Bordeaux–Bayonne line which continues over the Spanish frontier via Hendaye. There is a commercial airport at Poitiers-Biard.

The town's chief commercial activity is its trade in the wheat, wines, timber, and cattle from the surrounding plain and heathland. The fair held every Oct. 18 is an international market for grass seed. There has been considerable development of industry at the suburbs of Chasseneuil (electric batteries), Saint-Benoît (chemical products), and Pointe-à-Miteau. A characteristic occupation is the dressing of downy goose skins (called swan skins) for the luxury trade.

History.—First occupied by the Celtic Pictones or Pictavi (hence its name), Poitiers became an important Roman town under the name of Limonum. Having been ruled by the Visigothic kings of Aquitaine, it saw the defeat of the Visigoths by Clovis' Franks at the Battle of Vouillé (507); the halting by Charles Martel of the Islamic invasion of Europe (732); and the famous battle of 1356 (see below) during the Hundred Years' War. Some of the offices of royal government were removed to Poitiers between 1418 and 1436; Joan of Arc underwent an interrogation there in 1429. After a revival from the 14th to the 16th century the town sank into a torpor from which it gradually recovered during the 19th century. (See also POITIERS, COUNTS OF.)

The Battle of Poitiers, 1356.—This encounter, from its location more accurately called the Battle of Nouaillé-Maupertuis, was the second of the three great English victories of the Hundred Years'

War and took place in September 1356. It began with a foray from Bordeaux toward Bourges by the 7,000-strong Anglo-Gascon Army of Edward the Black Prince, which then withdrew toward Poitiers via Tours and the Clain River Valley. But the larger French Army of King John II the Good cut them off by crossing the Vienne River at the Chauvigny Bridge, having reached this point from Chartres via Blois. The commander of Edward's Gascons, who outnumbered the English, was Jean III de Grailly, *captal de Buch*. He was also the real leader of the cavalcade. The Black Prince's right-hand man, Sir John Chandos, was the *de facto* English leader and hero of the battle. The Army was accompanied by wagonloads of booty and the whole expedition was well-organized. The French Army, however, consisted of an assemblage of very independent-minded knights and was disunited.

Hostilities began on the morning of Saturday, Sept. 17, when the Anglo-Gascons ambushed a small French detachment at La Chaboterie. They then pushed on to Nouaillé Wood, where they could conceal their dispositions, and used it as their key position throughout the battle. A truce, observed throughout Sunday, Sept. 18, at the instance of the papal legate Hélié Cardinal de Talleyrand-Périgord, was spent by the Anglo-Gascons in preparing the ground and by the French, somewhat injudiciously, in eating, drinking, and sleeping. At dawn on Sept. 19, a small party of English feigned flight down the bad Maupertuis road along the west side of Nouaillé Wood, so drawing the French vanguard into hedges and marshy ground where it became bogged. Meanwhile King John had arrived with the rest of his army at a small clearing within an arm of the Miosson to the west of Maupertuis. The Anglo-Gascons gradually surrounded it and the Gascon captain De Grailly led the final charge which captured the French king and a number of his knights. Booty and a large number of prisoners were sent to Bordeaux. Four years later the Treaty of Brétigny (*see* BRÉTIGNY, TREATY OF) included Poitou, with the whole of Aquitaine, in the territory ceded by John II to Edward III of England.

See AQUITAINE; ELEANOR of Aquitaine; HUNDRED YEARS' WAR. (Jo. Sa.)

POITOU, a former province of France, bounded west by the Atlantic, north by Brittany, Anjou and Touraine, east by La Marche and Limousin, and south by Angoumois and Aunis, thus roughly corresponding to the modern *départements* of Vienne, Deux-Sèvres, and Vendée (*qq.v.*). The Seuil du Poitou, a zone of sedimentary rocks about 60 mi. (96 km.) wide between two higher countries of older rocks (Limousin and the southern part of the Massif Armoricaire), forms the easiest passage between northern and southwestern France.

Poitou derives its name from the Gallic tribe of Pictones or Pictavi, whose *civitas* or community formed part of Roman Aquitania. For centuries the northern part of Aquitaine (*q.v.*), it was a border country and a battlefield (Battle of Vouillé in 507 between Franks and Visigoths; Charles Martel's victory of 732 over the Muslims; the Anglo-French Battle of Poitiers in 1356; and the Battle of Moncontour in 1569 between Catholics and Huguenots) as well as the meeting place of northern and southern cultures. Its golden age (11th–12th centuries) is represented by a great school of Romanesque architecture, sculpture, and painting. The great counts of Poitiers (*q.v.*) were succeeded by the Angevin kings of England in the 12th century, but Philip II Augustus and Louis VIII of France conquered the country early in the 13th. Poitou was ceded to the English by the treaties of Brétigny and Calais (1360), but by 1375 the French had won it back. Poitou suffered in the Wars of Religion; its later history was quieter, apart from the Wars of the Vendée (*q.v.*) in the Revolutionary period.

POKEBERRY (POKEWEED), the popular name (from the American Indian *pocan*, applied to any plant yielding a red or yellow dye) of *Phytolacca americana*, a strong-smelling perennial herb, native of North America. It has ovate-lanceolate sharp-pointed leaves, racemes of small greenish-white flowers and flat-

tish berries nearly $\frac{1}{2}$ in. in diameter, which contain a crimson juice. The young asparaguslike shoots are sometimes used as a potherb, but the roots are poisonous. The plant is often cultivated in Europe, and has become naturalized in the Mediterranean region.

POKER, a card game played in various forms throughout the world. Its popularity is greatest in the English-speaking countries and after the 1850s it was called "the national card game of the United States." Because Queen Victoria found the principle of the game interesting, poker had a brief vogue in British court circles in the 1870s, but its acceptance in Great Britain and on the continent came chiefly in the decade 1911–20 and was undoubtedly much influenced by the American Expeditionary Forces in World War I.

For nearly 100 years in the United States poker was considered a gambling game for men, unsuited to polite or mixed gatherings, but after the 1920s its popularity extended to both sexes and all levels of society. Surveys made in the second half of the 20th century showed poker to be the favourite U.S. game of men and the third-most-favoured (after rummy and bridge) with women; and in Great Britain it ranked next after contract bridge with both sexes.

In one respect poker is rather a family of games than a single game (*see* *History*, below). It is played in countless variants and at least 150 are named and described in the literature of the game. All forms of poker, however, share certain essential features: A poker hand comprises five cards. The value of the hand is in inverse proportion to its mathematical frequency; that is, the more unusual the combination of cards, the higher the hand ranks. Each player may bet that he has the best hand, and other players must either "call" or meet his bet or concede. Therefore a player may "bluff" by betting he has the best hand when in fact he does not, and he may win by bluffing if players holding superior hands will not call his bet.

GENERAL PRINCIPLES OF POKER

The following principles apply to nearly all forms of poker:

Players.—There are forms of poker suitable to any number of players from 2 to 14, but in most forms the ideal number is 6, 7 or 8 players.

Cards.—Poker is almost always played with the standard 52-card deck, the cards in each of the four suits (♠, ♥, ♦, ♣) ranking A (high), K, Q, J, 10, 9, 8, 7, 6, 5, 4, 3, 2, A (low only in the straight or straight flush 5–4–3–2–A and in certain variants described below).

Wild Cards or "Freaks."—A wild card stands for any other card its holder wishes to name. There are many methods of introducing wild cards into the game. The most popular are: (1) Joker; a 53-card pack is used, including the joker as a wild card. (2) Bug; the same 53-card pack including the joker is used, but the joker (here called the bug) counts only as a fifth ace or to fill a flush, straight or special hand (described below). (3) Deuces wild or freak pots; all four deuces are wild cards. (4) One-eyes; in the usual British or U.S. pack, the ♦K, ♠J and ♥J are the only cards shown in profile. They are often designated as wild cards.

Rank of Poker Hands.—The traditional, universally accepted ranking of poker hands, from highest to lowest, is:

1. Straight flush: five cards of the same suit and in sequence. The highest straight flush is A-K-Q-J-10 of the same suit, called a royal flush; the lowest straight flush is 5-4-3-2-A of the same suit.
2. Four of a kind, as all four 6s, with any fifth card.
3. Full house or full hand: three of one kind and two of another, as 10-10-10-3-3.
4. Flush: five cards of the same suit.
5. Straight: five cards in sequence, in two or more suits. The highest straight is A-K-Q-J-10, the lowest 5-4-3-2-A.
6. Three of a kind or triplets, with any two other cards, not a pair.
7. Two pairs, as A-A-9-9 and any fifth card.
8. One pair, with three unmatched cards.
9. No pair, each such hand being rated by its highest card or cards, as ace high or ace-king high.

When there is any wild card in the game the highest possible hand is five of a kind, which beats any straight flush.

As between two hands having combinations in the same cate-

gory, the winner is determined as follows:

Straight flushes, flushes, straights or no pair: the one containing the highest card wins; if these cards are identical in rank, the next-highest decides and so on. Four of a kind or three of a kind (or five of a kind): the one composed of the higher-ranking cards. Full house: the higher three of a kind. Two pairs: the highest pair; if these are identical, the higher of the second pairs; if these are identical, the higher of the unmatched cards. One pair: the higher pair; if the pairs are identical, the highest of the unmatched cards and so on. When there are several wild cards there may be identical fours of a kind or threes of a kind, in which case ties are broken by the highest unmatched cards or secondary pairs (in a full house).

Two or more identical hands tie and divide any winning equally. The suits have no relative rank in poker.

In some games value is accorded to one or more (but seldom all) of the following special hands or to other combinations arbitrarily adopted by the players.

1. Big tiger or big cat: king high, 8 low, no pair, as K-J-10-9-8.
 2. Little tiger or little cat: 8 high, 3 low, no pair, as 8-7-6-5-3.
 3. Big dog: ace high, 9 low, no pair, as A-Q-J-10-9.
 4. Little dog: 7 high, 2 low, no pair, as 7-5-4-3-2.
- (Tigers and dogs rank in the order listed. Any tiger or dog beats a straight but loses to a flush.)
5. Skeet: five cards, 9 high, including 9,5,2, no pair, as 9-7-5-3-2; beats a straight, loses to a flush.
 6. Skip straight or Dutch straight, as 2-4-6-8-10; or round-the-corner straight, as 3-2-A-K-Q; beats three of a kind, loses to a straight. (The name pelter or kilter is sometimes applied to the skeet or skip straight.)
 7. Blaze: five face cards, as K-Q-Q-J-J; beats any two pair, loses to three of a kind
 8. Four-flush: four cards of the same suit; beats one pair, loses to two pairs.

As between two special hands in the same category, ties are broken as between regular poker hands.

Object of the Game.—The object is to win the "pot," which is the aggregate of all bets made by all players in any one deal. The pot may be won either by having the highest-ranking poker hand or by making a bet that no other player calls.

Preliminaries and Rotation.—At the start of the game any player takes a pack of cards and deals them in rotation to his left, one at a time face up, until a knave (jack) appears; the player receiving that card becomes the first dealer. The turn to deal and the turn to bet always pass from player to player to the left. For each deal, any player may shuffle the cards, the dealer having last right. The dealer must offer the shuffled pack to his right-hand opponent for a cut. If that player declines to cut, any other player may cut.

Betting Procedure.—In each deal there are one or more betting intervals. In each betting interval one player, as designated by the rules of the variant being played, has the privilege or obligation of making the first bet. This player and each player in turn after him must place in the pot a number of chips (representing money, for which poker is almost invariably played) to make his total contribution to the pot at least equal the total contribution of any player before him. When a player does this he is said to be in the pot or an active player. If a player declines to do this, he discards his hand and is said to drop or pass and he may no longer compete for the pot.

Before the deal, each player may be required to make a contribution to the pot, called an ante. In each betting interval, the first player to make a bet is said to bet; a player who exactly meets the last previous bet is said to call or stay (in); and a player who bets more than the last previous bettor is said to raise. In some variants a player is permitted to check, which is to stay in without betting, provided no other player has made a bet in that betting interval.

At the end of each betting interval except the last, dealing is resumed; at the end of the last betting interval there is the "showdown," in which each active player shows his full hand and the highest-ranking hand wins the pot. In practice, especially in informal games, players usually announce the values of their hands and show their hands as confirmation only, but on demand of any player the full hand must be shown and any mistaken announce-

ment is not valid: "The cards speak for themselves."

Betting Limits.—In poker legends there were "no-limit" or "sky's-the-limit" games, but in practice some limit is placed on what one may bet in any game. There are three popular methods.

Fixed Limit.—No one may bet or raise by more than the established limit. In draw poker the limit is usually twice as much after the draw as before; for example, two chips before the draw, four chips after. In stud poker the limit is usually twice as much in the final betting interval as in previous betting intervals. (The higher limit applies also when any player's exposed cards include a pair.) These respective forms of the game are described below. In a fixed limit game a limit is usually placed on the number of raises that may be made in any betting interval.

Pot Limit.—A player may bet or raise by no more than the amount in the pot at the time the bet or raise is made. When raising, he may first put in the pot the number of chips required to call the previous bet and then raise by the number of chips in the pot. When pot limit is played, it is customary also to place a maximum limit on any bet or raise, regardless of the size of the pot or to play table stakes.

Table Stakes.—This method most closely approximates the legendary no-limit game. Each player's limit is the number of chips he has on the table at the beginning of the deal. He may not bet more, but for this amount he may call any higher bet and compete for the pot in the showdown. Other players having more chips may continue to bet, but their further bets go into one or more side pots in which the winner is decided as among the players who contributed fully to the side pot. When a player drops out of any side pot he has dropped out of the original pot as well, in effect surrendering his rights in the original pot to the player whose later bet he did not call.

PRINCIPAL FORMS OF POKER

Poker has two main branches: closed (straight or draw) poker, in which each player's full hand remains concealed until the showdown; and open (stud) poker, in which some but not all of a player's cards are dealt or turned face up. Within each of these branches, but especially in closed poker, there are "pass-and-out" games, in which a player must bet or drop in each turn, and "pass-and-back-in" games, in which in certain circumstances a player is permitted to check.

Straight Poker.—Each player is dealt five cards, face down. There is one betting interval, beginning with the player nearest dealer's left, then a showdown. This was the original form of poker and has almost passed out of existence except, paradoxically, in the highest-stake games among professional gamblers.

Draw Poker.—This game has two main branches: (1) blind opening, played almost to the exclusion of other variants in England, Europe and the British Commonwealth except Canada, and favoured in men's clubs in the U.S. and Latin America; and (2) jackpots, the draw poker variant most played in the U.S. and Canada. In draw poker, each player is dealt five cards, face down. There is a betting interval. Then each active player, in turn beginning at dealer's left, may discard one or more of his original cards and receive replacements for them, dealt from the undealt portion of the pack. (A player who declines to draw cards is said to stand pat.) After this process, called the draw, there is a final betting interval, followed by the showdown.

Blind Opening.—There are three contributions to the pot before the deal. The dealer (or in some games, every player) puts in an ante, which does not rank as a bet. The player at dealer's left, formerly called the "age" or "edge," now called the opener, makes an opening bet of one chip or unit, called the blind. The player at his left puts in two or three units, constituting a call of the blind opening bet and a raise of one or two units; this is called the straddle or blind raise. Each player in turn thereafter may call (for the amount bet by the preceding player), raise (by one unit) or drop. The limit before the draw is usually the one unit of the ante. The limit after the draw is twice this amount or more; in some games it is the amount bet by each player before the draw. After the draw the betting begins with the active player nearest the dealer's left, and checking is permitted.

Jackpots.—Before the deal, each player antes one chip of lowest value. The game is pass-and-back-in both before and after the draw. In the first betting interval each player in turn, beginning with the one at dealer's left, may check (called also pass) or open (make the first bet); in most games a player may not open unless he has jacks or better (a pair of jacks or any higher-ranking hand), but the requirements for openers may be set higher or lower. If any player opens, each player in turn after him may call or raise until the betting interval is ended. There follow the draw, a second betting interval beginning with the opener (or if he has dropped, with the active player nearest his left), and a showdown. There are penalties for opening without openers (see *Laws*, below). In a similar game, called passout, no openers are required and the game is played pass-and-out (see above) before the draw.

Stud Poker.—Each player receives one card face down, called his hole card, then one card face up. The deal is then interrupted for a betting interval. There follow three rounds of dealing, each consisting of one face-up card to each active player, with a betting interval after each round. There is a showdown in which the hole cards are shown after the fourth and last betting interval. In each betting interval the first bettor is the player with the highest-ranking poker combination in his face-up cards; if two or more players have the same combinations, the "first" one (nearest the dealer's left) bets first. In the first betting interval the high player must bet at least an established minimum; in any later betting interval he may check. Few games have lost popularity so fast as regular five-card stud. In the 1920s and into the 1930s it was played in two-thirds of the high-stake and professional games in the U.S.; after the 1950s it was not played in one-tenth of them.

Seven-Card Stud.—Each player is dealt two hole cards, then a face-up card, followed by a betting interval; then three more face-up cards and one final face-down card, each followed by a betting interval. For the showdown each player selects the best five of his seven cards to be his poker hand. There are six-card and eight-card variants of this game, in each of which a player ultimately selects five of his cards.

High-Low Poker.—The highest-ranking poker hand and the lowest-ranking poker hand divide the pot equally. If there is an odd chip, the high hand gets it. If two or more hands tie for high or low, they divide their half of the pot equally. Nearly any form of poker may be played high-low. In most games the lowest possible hand is 7-5-4-3-2 in two or more suits, but in some games the ace may optionally be treated as the lowest card and 6-4-3-2-A becomes the lowest hand, while a pair of aces is the lowest pair.

High-Low Seven-Card Stud.—The high and low hands divide the pot, but each player may select any five of his cards as his candidate for high hand and any five as his candidate for low hand and so win the entire pot. In some games declarations are required: before the showdown each player must announce whether he is trying for high, for low or for both, and he cannot win unless his entire announcement is fulfilled.

Low Poker or Lowball.—This is draw poker played similarly to jackpots except that a player may open on any hand and the lowest-ranking hand wins the pot. In California, where the game is most popular, straights and flushes never count and the ace is always the lowest-ranking card, so the lowest possible hand is 5-4-3-2-A regardless of suits, called a bicycle or wheel.

Dealer's Choice or Dealer's Option.—In informal poker games, each successive dealer is usually permitted to dictate the variant of poker that will be played. This privilege is most often expressed by the dealer's selecting one of the forms of poker described above. He may also designate certain cards to be wild. Sometimes it is agreed that the dealer can select or invent any variant he wishes, subject to only two restrictions: the dealer cannot require any player to ante more than any other player; if the game requires a minimum to open (as jackpots) and is passed out, the same dealer deals again.

LAWS OF POKER

No code of poker laws has been universally adopted as the laws of bridge have been. Nearly every club or serious game has cer-

tain house rules that may differ in some respects (usually minor) from those of other clubs and groups. The usual practice is to adopt a published code and add the house rules to it. A code prepared by O. Jacoby in 1940 and another (nearly identical in substance) appearing in *The Official Rules of Card Games* since 1945, are the ones most often adopted in the United States. Poker laws, unlike those of other card games, provide only rectification and no penalties for irregularities.

Certain departures from regular procedure are necessarily treated differently in draw poker and stud poker. The following summary follows the Jacoby code.

Laws Applying to All Forms of Poker.—**Misdeal.**—The same dealer deals again with the same pack if: a card is exposed in the cut; two or more cards are exposed in the deal; the pack is found to be imperfect (but after the next deal begins, all previous deals stand); a player is dealing out of turn and attention is drawn to that fact by a player who has not looked at any of his cards. If one card is exposed during the deal the player must take it.

Betting.—Money (chips) put in the pot may not be removed for any reason; except that in a jackpots game when a player has opened illegally each other player may remove his chips bet after the pot was opened and before the disclosure of the false openers. A player has no redress if he misunderstood a previous bet or announcement. In table stakes a player may never bet more than his entire stack.

Action Out of Turn.—An announcement out of turn of intention to drop or bet is binding, but is temporarily canceled pending action by any player rightfully in turn. When the offender's turn comes, he may forfeit the announced amount and drop, if that amount was insufficient to call; he may if necessary add enough to call but not to raise; he is deemed to have raised by any excess of the announced amount over the amount necessary to call. (In some games action out of turn is simply void.)

Incorrect Number of Cards.—A player who has only four valid cards may play on but may not make a flush, straight or any special hand based on five cards. (In many games a four-card hand is dead and cannot win the pot.)

Laws Applying to Draw Poker.—**Incorrect Hand.**—If one player is dealt four cards, another six, and if neither has looked at his hand, the former draws a card from the latter; if either has looked at his hand, the hand is foul (cannot win the pot). If a player has not looked at his hand and has four cards, the dealer gives him another from the top of the pack; if he has six cards, the dealer draws one card and places it on the bottom of the pack.

Card Exposed During the Draw.—If the card was faced in the pack, it is discarded and the draw continues. If the card was exposed in dealing, it is discarded and the player is given a replacement after all other players have drawn.

Wrong Number of Cards Drawn.—A player must take the number of cards he asked for, unless he corrects himself before he looks at any card drawn and before the next player has drawn. If he has discarded, he may discard more to make room for additional cards or he may if necessary play on with four (but no fewer) cards; he may not reclaim any discard. If he has been given too many cards and looks at any of them, his hand is foul. He has no redress whether an error was his or the dealer's.

Insufficient Cards in Pack.—The bottom card of the pack may not be dealt. If there are too few cards remaining to complete the draw, the dealer gathers together all discards of players who have dropped or have already drawn, shuffles them, has them cut and continues the draw. The opener's discards, if identifiable, are exempted.

Laws Applying to Stud Poker.—**Incorrect Hand.**—If a player, for any reason, has an incorrect number of cards his hand is foul.

Exposed Card.—If a hole card is exposed accidentally in the deal, the dealer gives the player his next card face down. A player may not intentionally expose a hole card and receive a subsequent card face down; he may play on with that card exposed. If a card to be dealt is exposed before a betting interval is ended, then that card and one card for each other active player

are buried before the deal is resumed.

Insufficient Cards in Pack.—The bottom card of the pack may not be dealt. If there are not enough cards to complete every active player's hand, the dealer flashes (exposes) a card instead of dealing the last round, and the exposed card is considered the last card of every active player's hand.

SKILLFUL PLAY

Poker better rewards skillful play than any other card game. Though it is not so complex a game as bridge and numerous other games, the player has greater control over the result (largely because he is permitted to drop bad hands); consequently a good player is less likely to lose in a game with inferior players.

Since poker has a mathematical basis (the less probable a particular holding, the higher its rank), the science of the game begins with the relative expectancies of the several hands, though this is only background knowledge that seldom has practical application in play.

There are possible 2,598,960 different five-card hands that may be dealt from a 52-card pack, as follows:

Possible Poker Hands in 52-Card Pack

Hand	No. possible	Chance of being dealt
Straight flush.....	40	64,974
Four of a kind.....	624	4,165
Full house.....	3,744	694
Flush.....	5,108	509
Straight.....	10,200	256
Three of a kind.....	54,912	48
Two pairs.....	123,552	21
One pair.....	1,098,240	2.5
No pair.....	1,302,540	2

A person beginning the study of poker on purely theoretical grounds would find such a table indispensable. It would tell him, for example, that if he is dealt a flush there are only a few thousand possible hands that might beat him while there are more than 2,500,000 he can beat, whereupon he would be justified in making or calling a maximal bet.

From a practical standpoint, the player needs chiefly to know what constitutes a good hand, a fair hand and a poor hand in a given form of poker. Experience as well as mathematics indicates the following as the average winning hands in the forms of poker most frequently played.

Game	Average winning hand
Draw poker, nothing wild.....	Jacks up
Five-card stud.....	Aces or kings
Seven-card stud.....	3 eights
Draw poker, joker wild.....	3 eights
Draw poker, with bug.....	Aces up
Draw poker, deuces wild.....	3 aces
Draw poker, high-low.....	Jacks up high; 10 or 9 low
Lowball.....	9-6-x-x-x

The fundamental principle of skillful play is that a person should stay in the pot only if: (1) he probably has the best hand or (2) the odds against his drawing the best hand are less than the odds offered by the pot. To illustrate the latter: There are four chips in the pot and the player must put in one chip to stay; therefore the pot offers 4-to-1 odds. The player has a four-flush or "bobtail" straight (open at both ends as 8-7-6-5), to either of which he can draw one card. The odds against filling either of these hands ranges $4\frac{1}{5}$ to 1. The pot offers less than the odds against filling, so the player should drop.

The approximate odds against improving the original hand in draw poker are as follows:

Hand	Odds against improving
One pair.....	$2\frac{1}{2}$ to 1
Two pairs.....	11 to 1
Three of a kind.....	$8\frac{1}{2}$ to 1
Straight, open.....	5 to 1 (39 to 8)
Straight, inside (as 8-7-5-4).....	11 to 1
Straight flush, open.....	2 to 1
Straight flush, inside.....	3 to 1

In five-card stud poker it is wise to stay in only if one has a

pair, a hole card higher than any card showing or a card at least as high as any card showing plus another high card. It is never wise to stay in when another player has showing a pair higher than one's own pair (or if one has no pair). In seven-card stud, it is usually best to stay in only if one has a pair, three cards of the same suit or three cards in sequence. In seven-card high-low stud, the guiding principle is to play for low.

The only hand with which to play for high is three of a kind in the first three cards.

Bluffing and psychological play, though they are of essential importance, depend more on experience and moral ascendancy than on rules of play or maxims.

HISTORY

The principle of poker is very ancient. One of its ancestral games (Sp. *primero*, It. *primiera*, Fr. *la prime*) appears in literature at least as early as 1526. In this game each player had three cards and the counting combinations were three of a kind, a pair and a flush (flush), three cards of the same suit. In later developments certain cards had special value, equivalent to wild cards in modern poker. By about 1700 the betting and bluffing aspects had produced the games brag in England (one of four card games about which Edmond Hoyle wrote) and *pochen* (Ger. "to bluff") in Germany. From the latter the French developed a similar game called *poque*, played in French America in 1803, when the Louisiana purchase made New Orleans and its environs territories of the United States. During the next 20 years English-speaking settlers in the Louisiana territory adopted the game, anglicized its name to poker and established the essential features of the modern game.

The earliest-known reference to poker in American literature occurs (1829) in the memoirs of Joe Cowell, a touring English actor. From his description it is clear that the original American game was played with a pack of cards that included five cards for each player: all the cards were dealt and the players bet on which had the best five-card combination.

So played, poker is virtually indistinguishable from an older Persian game called *As nas*, a four-hand game played with a 20-card pack, five cards dealt to each player. This coincidence had led some students of games to call poker a derivative of *As nas*, but there is no record of any connection between the two.

By 1834, the date of the second known reference to poker, the game had been adapted to the 52-card deck. No description of poker is given in any book of the rules of games before 1858, but in such books published in the 1860s it is not characterized as a new game. The history of the game since then consists entirely of new features introduced to encourage freer betting: the straight, introduced as an additional valuable hand; the draw, so that players might stay in even when they were not originally dealt good hands; stud poker, to increase the number of opportunities for betting; jackpots, originally only applying to a pot to which each player antes, creating an unusually large pot at the start. Most of these innovations came in the decade 1861-70 and probably were engendered in the great amount of poker played by soldiers on both sides in the Civil War.

The spread of poker to other countries probably began in 1871 when Col. Jacob Schenck, the U.S. minister to Great Britain, explained the game to a group of gentlemen including members of the British court. Queen Victoria heard about the game and expressed interest, whereupon Schenck wrote and had privately printed (1872) a set of rules to send to her. This is the earliest-known work devoted exclusively to poker, although the game had previously (1858, 1864, etc.) been treated in compendiums. Poker was already sufficiently identified with the United States so that Schenck described it as "our national game." However, this may have been only because all other card games played in the U.S. were undeniably of European origin.

Whether rapidly or gradually, between 1870 and the end of the 19th century, poker became a matter of general knowledge in the United States, and early in the 20th century it spread to other parts of the world.

See Oswald Jacoby on *Poker* (1947) for the game as played in the

U.S.; Maurice Ellinger, *Poker* (1950) for the game as played in England. (O. Jv.; A. H. Md.)

POKOMAM AND POKONCHÍ, two closely related dialects of the easternmost Highland Maya. Culturally the people who speak them are very similar and in the 16th century they were scarcely distinguishable, even linguistically. Speakers of Pokomam in the 1960s numbered about 100,000, and of Pokonchí nearly 50,000, in the departments of Alta Verapaz, Baja Verapaz, El Progreso, Guatemala, Jutiapa, Chiquimula, Zacapa, and Jalapa in Guatemala (*q.v.*). Until the 19th century Pokomam was spoken in several towns in western El Salvador. In the period c. A.D. 850, these peoples produced some of the finest figure-painted ceramics in the Americas. Contemporary hispanicized life shows remnants of the politics and clan and hierarchical society described by B. de Las Casas (*q.v.*) in the 16th century. Christianized simple burial practices contrast with magnificent old tombs (see *ARCHAEOLOGY: Mesoamerica*). Ancient tomb-shrines are still adoratories, modern myths and dances perpetuating traditions of earlier days. The count of the 20 day names of the old Maya calendar is still employed in healing and fortunetelling. See also *CALENDAR: Middle American Calendars; MAYA INDIANS*.

POLABS (POLABIANIE; from *po*, "along," *Laba*, "Elbe"), the westernmost Slavs of Europe, dwelt between the lower Elbe to the west, the Baltic to the north, the lower Oder to the east, and Lusatia (*q.v.*) to the south. In Charlemagne's time they were organized in two confederations or principalities, the Obodrites (*q.v.*) in the west and the Lutycy or Wilcy in the east. The latter comprised many tribes, of which the Ratarowie (Ger. Redarier) and Stodoranie or Hawolanie (Ger. Heveller) were the most important. The Lutycy, who had allied themselves with the German king Henry II against Boleslaw I of Poland in 1003, were subdued by the Germans in the 12th century: Lothair of Saxony destroyed Radogoszcz (Rethra), the Ratarian capital, in 1121; and the margrave Albert the Bear began a war against the Hawolanie in 1147 and incorporated their lands in Brandenburg when their prince, Pribislav, died childless in 1150. Even so, the Polabian language, related to Kashubian (Cassubian, Kaszub) and Polish, survived on the Lüneburg Heath till the beginning of the 19th century. (K. Sm.)

POLAND (POLSKA), a country of east-central Europe lying between the Baltic Sea to the north and the Sudetes and Carpathian mountains to the south and bounded, since 1945, on the east and northeast by the U.S.S.R., on the south by Czechoslovakia, and on the west by Germany. Its area is 120,359 sq.mi. (311,730 sq.km.), and population (1960 census) 29,775,508. The capital is Warsaw (Warszawa).

I. PHYSICAL GEOGRAPHY

1. Structure and Relief.—The main morphological features have been molded by two great influences: the northward thrust of the Alpine-fold mountains against the Hercynian plateaus (represented there by the Bohemian Massif and the submerged Polish Platform which reaches the surface in the Lysa Gora [Lysica], east of Kielce) and the southward invasions of the Scandinavian ice sheet. Conditioned by these influences the natural regions tend to form zones running broadly east and west across the country.

In the extreme south, the mountain frontier zone is divided into two sections. The first, composed of the older, peneplained rocks of the Sudetes Mountains, reaches its highest point in Mt. Sniezka (5,259 ft. [1,603 m.]) in the Giant Mountains; the second, formed by the young fold mountains of the Carpathians, assumes a truly alpine appearance in the High Tatra, the highest point of which, Gerlachovka (8,737 ft. [2,663 m.]), lies across the frontier in Slovakia. The submontane zone of southern Poland, consisting of upland-rimmed river basins interconnected by narrow gateways, is again capable of subdivision. Thus Silesia, drained northwestward by the Oder, forms a unity centring upon Wrocław (Breslau); bounded on the north by the Kocie Hills near Trzebnica, this basin contains extensions of the great carboniferous deposits of north-

western Europe. The sub-Carpathian basins, on the other hand, occupy a tectonic hollow running from the Moravian Gate through the small Oswiecim Basin and the Cracow Gate to the wider Sandomierz Basin drained by the Vistula and San. The Little Polish (Malopolska) Tableland, between the Silesian and sub-Carpathian basins, consists of the Cracow-Czestochowa limestone plateau (reaching 1,653 ft. [504 m.]), which opens southeastward to the Tertiary deposits of the Nida Basin, and the Holy Cross (Swietokrzyskie) Mountains (Lysa Gora, 2,005 ft. [611 m.]). The south-eastern edge of the latter, the Sandomierz Tableland, is noted for its fertile loess deposits. Finally, east of the Vistula the upland rim is represented by the Lublin Tableland, with its rich soils derived from chalk marl, and the Roztocze ridge.

The remainder of Poland is dominated by glacial features. The characteristic east-west sectors of the great rivers and their tributaries (e.g., the lines formed by the Bug-Vistula-Notec-Warta and the Warta-Obra-Oder) mark stages in the successive northward retreat of the ice sheet, when drainage was forced toward the west. Central Poland, an undulating country crossed by the great valleys, includes the Great Polish (Wielkopolska) and Kujavian lowlands around Poznan and the Mazovian Podlaskan lowlands around the capital city, Warsaw. The soils are based on fluvio-glacial and fluvial deposits. Farther north, breached by the Oder and Vistula in their lower courses, lies the Baltic lake zone, Pomorze (Pomerania) to the west and Mazovia to the east of the Vistula. It is a region of classic morainic topography: boulder clay, sands and gravels form hummocky ridges, often reaching more than 650 ft. (198 m.) in height and interspersed with numerous lake-filled, peaty hollows. The morainic hills descend to a low sandy plain skirting the Baltic coast. Along this coast, with its slight tidal range, longshore drift eastward has modified deltaic construction by the Oder and Vistula to produce classic examples of lagoon-and-bar formation as the Vistula Lagoon (Zalew Wislany or Frisches Haff; *q.v.*) and the Stettin Lagoon (Zalew Szczecinski or Oder Haff). Such deposition had hindered access to the older ports such as Elblag (Elbing).

2. Climate.—Climatically, Poland belongs to the major zone which includes eastern Germany, most of Finland, and western U.S.S.R. It is open to the influence of the prevailing, variable, westerly winds, except when these are replaced during winter by the heavy masses of cold air cushioning the interior of the continent. Summers are warm or very warm, according to distance from the sea and latitude, although temperatures in the south are modified by the increasing altitude. Winters are cold and are particularly unpleasant when pressure conditions allow an influx of strong winds from the Russian plains. Temperatures are below freezing point for at least two winter months in the west and three months in the east. The Oder, for example, is frozen for an average of 80 days, the Vistula 80–100 days, and the Baltic harbours, especially where distant from the open sea, are icebound for a period every year—Swinoujscie for 20 days on the average, Szczecin (Stettin) for 61 days. The open Baltic itself is frequently impeded by drift ice, but navigation usually continues along the sea-lanes connecting the favourably placed docks of Gdynia-Gdansk (Danzig). The following figures are typical mean January and July temperatures: Szczecin, 30.4° and 65° F (–1° and 18° C); Warsaw, 27° and 66° F (–3° and 19° C); Tomaszow Lubelski, 24° and 64° F (–5° and 18° C). Sniezka, with a range between 19° and 47° F (–7° and 8° C), and below freezing point for six months, is typical of conditions in the highest mountain regions; even in the Tatras, however, there are no permanent snows.

Precipitation, in winter mostly falling as snow, is moderate, 20–27.5 in. (508 mm.–698 mm.), except along the southern highland fringe. There is greater precipitation in the summer half year, because of the development of thundery conditions in early summer and of the passage of depressions in autumn. The skies are on the whole cloudy, mean cloudiness averaging somewhat less than seven out of ten pt.; the summers are brighter and less humid, although more rainy, than the winters. Wroclaw is representative, with a mean annual precipitation of 23.3 in. (591 mm.) and cloudiness of 6.8 pt.; precipitation is distributed seasonally, in percentages of the total, beginning with winter, as follows: 16, 24, 38, and 22. Sniezka

has a mean annual precipitation of 45.6 in. (1,159 mm.), typical of the narrow mountain fringe.

3. Geographical Regions.—Six regions can be distinguished, defined broadly along east-west axes, and based on relief and land-use factors. Ranging inland and southward the regions are: the maritime lowlands, the Baltic lake zone, the central lowlands, the region of old mountains and highlands, the sub-Carpathian basins, and the Carpathian Mountains.

The *Maritime Lowlands* include the Szczecin Plain in the west and the low-lying coastal region, where the landscape is varied by large lakes (Lebske and Gardno) and sand dunes. The Zulawy region of the Vistula delta though vulnerable to floods is highly fertile and the considerably drained areas are important for agriculture and animal breeding. The main economic activity centres on the docks and shipyards of the ports of Szczecin, Gdynia, and Gdansk (Danzig), while the growing tourist industry is centred on Kolobrzeg, Darlowo, and Leba.

The *Baltic Lake Zone* characterized by glacial lakes and morainic hills embraces the two subregions, the Pomeranian and Masurian lake districts, lying respectively to the west and east of the lower Vistula. Agriculturally the area is highly diverse; contrasts in land use are related to detailed variations in soil and drainage conditions. With few resources other than timber and peat the zone is of little economic significance. It is, however, an area of considerable tourist potential.

The *Central Lowlands* may be divided into two sections, the Great Polish or Wielkopolska (Poznan area) and Kujavian lowlands in the west and the Mazovian Podlaskan lowlands in the east. The great parallel river valleys form the major east-west traffic routes. The region is of considerable agricultural importance, especially for cereal production. The two great urban focuses of Poznan and Warsaw are important centres of engineering and transport.

The *Old Mountains and Highlands* region farther south is considerably diverse and structurally complex with distinct subregions defined by the intersecting drainage of the upper Odra and upper Vistula. The region contains a variety of nonferrous minerals, e.g., the copper deposits in the Legnica district. Building materials are also an important product, e.g., the cement industry of Oppeln. In the middle section lies the major industrial area of the Upper Silesian coalfield.

The *Sub-Carpathian Basins* form a triangle narrowing toward the Cracow Gate which separates the western part of the Raciborz-Oswiecim Basin from the Sandomierz Basin. In the east lies an overpopulated traditionally agricultural area which remains comparatively backward economically. The post-1945 development of the Nowa Huta steelworks near Cracow was initiated to promote industrial activity in the region.

The *Carpathian Mountains* stretch from the Moravian Gate to the border with the Ukraine, U.S.S.R. A foothill zone is succeeded to the south by the Beskidy Uplands and then by the Podhale Basin which lies between the Beskidy and the southernmost massif of the High Tatras. The attractive landscape has made this region economically significant for its tourist industry, with a principal centre at Zakopane. Considerable attention has been given to the role of the Carpathians as the main water catchment area of Poland and a source of hydroelectricity. (G. W. S.; Ed. Br.)

4. Vegetation.—Poland belongs to the Central European floral region. The species which make up its flora include about 2,250 seed plants (Phanerogamae), 900 mosses and liverworts (Bryophyta), 1,200 Lichens, 10,000 Algae, and 12,000 species of Fungi, Myxomycetes, and other groups of the Cryptogamae. The most significant plant associations are forests, which cover 23% of the country. The economically important forests are the deciduous oak-hornbeam, beech, and alder forests; the mixed pine-oak and fir-beech forests; and the coniferous pine and spruce forests. Of the few endemic species two trees are worth mentioning; the Polish larch (*Larix polonica*) and the Ojcow birch (*Betula oycoviensis*).

Some relicts of the Ice Age (e.g., *Betula nana*) exist on the peat bogs and in the lake district. The lime and gypsum rocks and the loess areas have a thermophil vegetation of relict xerophils (*Stipa*

BY COURTESY OF THE POLISH CULTURAL INSTITUTE, LONDON

ZAKOPANE. A RESORT CENTRE IN THE TATRA MOUNTAINS NEAR THE POLISH-CZECHOSLOVAKIAN BORDER

pennata, *Prunus fruticosa*, and others) and Atlantic plant species (e.g., *Erica tetralix*) are present near the Baltic Sea.

In the mid-1960s, 10 national parks with an area of 159,229 ac. (64,439 ha.) and other nature reserves with a joint area of more than 57,000 ac. (23,000 ha.) were maintained to protect animals and plants. (W. Sz.)

5. Animal Life.—The fauna of Poland belongs to the zone of deciduous and mixed forests of the Palearctic region, and differs little from that of neighbouring countries. Roe deer, red deer, and wild boar predominate and inhabit mainly the deciduous forests. Typical birds of the coniferous forests in the north and the mountains are the nutcracker, capercaillie, and black grouse. Alpine species such as the chamois and marmot are encountered in the Carpathians, and the ground squirrel and hamster found mainly in the south are steppe elements.

The once-abundant fauna of the forests was harried by hunting and driven out by deforestation as early as the Middle Ages. The last aurochs (*q.v.*) was killed in 1627. The European bison (*Bison bonasus*) teemed in the Belovezh Forest until World War I when it was exterminated. A bison herd was later rebuilt from specimens preserved in zoological gardens and by the 1960s there were more than 100 bison in the Polish reserves, about half of them roaming at liberty. Elks and beavers are preserved in northeastern Poland, and bears, lynxes, and wildcats occur in the Carpathian forests. The lake district in the north has a rich avifauna including swans, cormorants, and cranes.

Trout and salmon, the latter becoming increasingly rare, live in the mountain rivers; lowland rivers and lakes are inhabited by eels, pike, perch, tench, and bream. (Ka. K.)

II. THE PEOPLE

1. Origins.—The Poles belong to the North Indo-European language group comprising also other Slavs, the Balts, and the Germans. As far back as the first half of the 1st millennium B.C. the Slavs and the Balts formed a nondifferentiated linguistic entity. Hence, the primordial homeland of the Slavs should be localized in the immediate vicinity of the most ancient settlements of Germans and Balts. This has been illustrated by the Polish anthropologist Tadeusz Sulimirski. He projected on the map of Europe the schema of the relationship between Indo-European languages prescribed by the German linguists Johannes Schmidt and Hermann Hirt. This diagram indicates that the area occupied by the Poles in the basins of the Oder and Vistula rivers corresponds to the

territory of the presumed primordial homeland of the Slavs. (See also SLAVS.)

The Polish nation originated from a union of the following west-Slavonic tribes: Polanians (Polans; *Polanie*), Vistulans (Vislans; *Wislanie*), Silesians (*Slazacy*), East Pomeranians or Cassubians (*Kaszuby*), and Mazovians (*Mazowszanie*). The factor uniting Polish tribes into a historic nation was the state ruled by the Polanian Piast dynasty which appeared in the middle of the 9th century, although the year 963 is the date first confirmed in historical sources. This state gave the name of Poles (*Polak*, plural *Polacy*) to the united tribes. To the present time, however, these tribes have preserved a feeling of belonging to their region, a certain local patriotism linked with their dialect, dress, and customs. This feeling was most vital among the Cassubians who were finally incorporated into the Polish state only in 1466. The Vistulans failed to preserve their traditional name, which was mentioned in historical sources of the 9th century (the so-called Bavarian Geographer and King Alfred). The conquest of the Vistulans (*Visle land* mentioned by King Alfred) in the 9th century by the Great Moravian state, its inclusion in the Czech state in the 10th century, and, finally, its participation in the state of Polanian Piasts and their successors, obviously obliterated from the memory of the people their traditional tribal name. They became Little Polanians (*Malopolanie*) while the original Polanians began to call themselves Great Polanians (*Wielkopolanie*).

The hypothetical limits of the Polish language in the year 1000, as established by Kazimierz Nitsch, indicate the extent of territorial losses sustained as a consequence of the germanization of the Great Polanians and Silesians. The boundary of the Polish language in 1750 shows the losses suffered during the previous centuries not only by the Silesians, the Great Polanians, and particularly the Pomeranians, but even by the Mazovians whose northern frontier region became germanized. (See POLISH LANGUAGE.)

From an anthropological point of view Poland is a part of central Europe. The main racial components of its population are the Nordic, Mediterranean, Armenoid, and Lapponoid elements. The last two elements are not distinguished by many anthropologists, who denote them jointly as the Alpine race. In a strip of the eastern border region of the Polish ethnic area small but tangible admixtures of the Paleo-Europeid or Paleo-Asiatic components may be discerned. These are strongly represented in archaic northeastern Europe and are a characteristic element of the Finno-Ugrian peoples; this element is supposed to be a remnant of the Mesolithic European populations.

The characteristic peculiarity of the anthropological structure of the population of Poland is that the region of the last glaciation corresponds to the zone of the strongest predominance of the Nordic element, while farther south the Lapponoid element is more numerous. Rather closely connected with this significant conformity of the anthropological and geological boundaries is the equilibrium line of the admixture of the two less essential components. The Mediterranean admixture prevails in the Nordic, and the Armenoid in the Lapponoid area. The equilibrium line of admixtures is a characteristic boundary separating anthropological central Europe from its northern periphery—an area with a decided prevalence of the Nordic anthropological element.

The equilibrium line of admixture runs from the mouth of the western Neisse (Nysa) toward the lower Warta, from the upper course of which it passes to the Vistula, reaching it in the vicinity of the mouth of the San River. From the Vistula it turns to the Bug River and encircles Polesie from the north. The deviation of the equilibrium line reaching far to the south between the Warta and Vistula is undoubtedly due to migratory movements in a southeastern direction. It is unknown whether this is only a consequence of the rule of the Piasts and their expansion from the 10th century onward, or whether it is the joint effect of that expansion and of the hypothetical expansion of the Baltic-Lekhitian Slavs which can be dated to the 7th century.

It is very probable that toward the end of the 6th century the incursion of the presumably Mongolian tribe of the Avars disrupted the political organizations formed in the sub-Carpathian and sub-Sudeten regions after the invasion of the Huns, and caused

not only the transfer of the Serbs, Croats, and Volhynian Dulebians to the west, and later to the south, but also enabled the Baltic-Lekhitian (Polabian) Slavs to subdue the continental Slavonic tribes as far as the Carpathian Mountains, including the Czechs. The hypothesis of an assumed Lekhitian state of such vast extent is supported by the results of linguistic, anthropological, and archaeological investigations as well as by the unequivocal though indirect evidence of the so-called Nestor *Chronicle* of the 11th century. Moreover, one might suppose that the attacks of Charlemagne against the Slavs reaching as far as the estuary and source of the Oder disrupted that state and liberated the continental Slavonic tribes; this enabled the Polanian Piasts to consolidate the continental Lekhitian tribes within the framework of a new, now Polish, state organism.

The historical Polish tribes are still clearly marked by anthropological differences. The Polanians, Kujavians, Pomeranians, and Mazovians preserved an anthropological composition closely related to the primordial Slavs, with a characteristic predominance of the Nordic element. On the other hand, beyond the zone transformed by the pressure of their northern neighbours, the tribes of Silesians and Little Polanians are characterized by a prevalence of the Lapponoid element. Hence it is possible that they became Polish only in consequence of the Lekhitian expansion.

One of the most essential results of ethnographic investigations is the assertion that Poland is transected by one of the most important cultural confines of Eurasia which runs from the Baltic to Tonkin Bay. This is the borderline between the limits of reach of two-shaft cart harnesses with one horse and harnesses with one-shaft carts and two horses. Primarily one-shaft harnesses were connected with cattle traction and have been later adapted to horse traction. The terminology of western Polish carts is of Upper-German origin and was introduced into Poland by way of Moravia. This would be an evidence that this revolution in the domain of transport coincided with the period of the growing influence of the Franconian monarchy at the time of the Samon state or, even later, of the Great Moravian state. It is significant that single (two-shaft) harness is used by the Finns, Balts, and Russians and was probably derived from Turkic and Mongolian nomads, whereas the Ukrainians still use the archaic one-shaft harness and cattle traction. In the territory of Poland the limit of one-horse harness seems to determine the boundary of the area ruled by the Balts that was in later times absorbed by the Polish ethnic expansion.

2. Religion.—The overwhelming majority of Poles (nearly 95%) belong to the Roman Catholic Church. The Polish Protestant Church and the Polish autocephalous Orthodox Church make up about 3% of the total number of citizens, and the number of Jews, which before World War II represented 10% of the population, was reduced by the German extermination policy to no more than 0.3%. The awareness of belonging to the Polish nation linked with Catholicism is a consequence of historical processes through which the Polish people passed during the last thousand years. When Poland was endowed with its own church hierarchy in 1000, and with the Gniezno archbishopric depending directly on Rome, it became an equal member of the European community of Christian lands. Since that time the church hierarchy has played an important role in Polish history. During the period of division of the kingdom into autonomous principalities (12th–14th centuries), when the supreme princely power did not have much authority, or in the period following the 18th-century partitions of Poland, when the nation was deprived of its own statehood, the Polish people were linked together by the church hierarchy. Furthermore, that hierarchy preserved the unity of the nation also where the state neglected to defend it. Although Casimir III the Great renounced in 1335 his claims to Silesia, that province remained until 1818 dependent on the Gniezno archdiocese.

This union of Poles with their church is reflected in the domain of folklore where festivities and rites, at first undoubtedly of pagan origin, became linked with church solemnities and observances. Traces of the most remote past can be found in archaic ritual songs of a pentatonic scale and in ordinances not connected with church ceremonies, as well as in amusements, especially in children's plays

and in postharvest celebrations which have the character of folk entertainments. (J. Cz.)

III. HISTORY

Poland's history begins in the year 963 when a German border knight came into contact with Mieszko I (*see* MIESZKO), who was prince of Poland till 992. The unity of the Polish state, surrounded as it was by other pagan and mostly Slavonic tribes, had been achieved under the descendants of Piast (said to have been either of peasant origin or an official at the court of an older dynasty), who founded the dynasty which gave his people strong and valiant rulers down to 1370. Mieszko's predecessors had succeeded not only in uniting a number of tribes but also in establishing a highly developed political community which had neither enjoyed the benefits nor suffered the disadvantages of contact with the high civilizations of western and southern Europe. To meet the dangers that arose when the Germans began to penetrate the barrier formed by the western Slavonic tribes, Mieszko conceived that policy of deliberately adopting western civilization which was the chief object of the rulers of Poland for several centuries. He secured his state from the aggression of his new neighbours by acknowledging himself a tributary of the Holy Roman emperor Otto I, and removed all danger of a hostile crusade by accepting Christianity for himself and for his people in 966 with the help of the Czech princess Dubravka or Dabrowka, whom he had married a year before. Finally he placed all his lands in the hands of the pope, thus inaugurating a close relationship that gave Poland the special protection of the Holy See. He seems to have been successful in gaining Pomorze (Pomerania; *i.e.*, the seaboard), but lost part of his eastern territory to the Russian prince Vladimir the Saint.

A. THE PIAST KINGDOM

Mieszko's son Boleslaw I the Brave (*see* BOLESRAW I; 992–1025) was one of the great soldiers and statesmen of his time. From the Congress of Gniezno (1000) with his friend the emperor Otto III, where he secured for Poland an independent church, organized in a number of bishoprics under a metropolitan at Gniezno, to his coronation as king (1025), he achieved the transformation of his father's principality into a powerful and independent kingdom. His wars of defense and expansion against Germany and Bohemia ended successfully in 1018; then he turned east and, during an armed intervention, occupied the Russian capital, Kiev. His younger son Mieszko II (1025–34) succeeded him as king, but the decentralizing tendencies of the nobles diminished the power of the kingdom in spite of its partial revival under Mieszko II's son Casimir (Kazimierz) I the Restorer (1039–58) and the strong rule of Casimir's son Boleslaw II the Bold (1058–79). But under Boleslaw III the Wry-Mouthed (1102–38), a nephew of Boleslaw II, Poland made great advances. Boleslaw maintained the independence of his country by a victory at Glogow when the emperor Henry V invaded Silesia in 1109. His reign saw a considerable cultural advance, and an anonymous chronicler recorded the earlier history of Poland. He collaborated with Otto, bishop of Bamberg, in converting the Pomeranians to Christianity after occupying and subduing the greater part of that area.

1. The Period of Division, 1138–1314.—Boleslaw III divided Poland among his sons, so that Poland, like its neighbours Germany and Kievan Russia, ceased to be a united state for two centuries. The capital was established in Cracow, the ruler of which was also prince of Silesia, and had "seniority" over his brothers, who ruled over Great Poland with Poznan and western Kujavia, Mazovia and eastern Kujavia, and Sandomierz. In each of these principalities there grew up round the Piast prince a powerful upper class consisting of the officials and the clergy headed by the local bishop, a process which modified the *jus ducale*, or ducal right, of the monarchical system. This period of divided loyalties laid the country open to many dangers; while the empire remained strong, a ruler like Frederick I Barbarossa in 1157 could assert his claim to Polish allegiance, and a major disaster like the Mongol or Tatar invasion in 1241 found the chivalry of Little (or southern) Poland unsupported and the heroic efforts

of Prince Henry II the Pious of Silesia (1238–41) made in vain. Worst of all were the incessant raids of the barbarian neighbours, notably the Lithuanians and Prussians. To avert these, Prince Konrad of Mazovia called in the Teutonic Order (*q.v.*), a purely German crusading organization that had lost a sphere for its activities in Palestine. Well established on the northern border, the order was helped by the Poles to occupy not only the borderland but the whole of Prussia, which was speedily colonized mainly by German immigrants. By a brilliant piece of diplomacy the grand master Hermann von Salza persuaded the emperor Frederick II to accept his homage as ruler of the newly acquired lands (1226). The divided Polish states found themselves face to face with a powerful German state on their northern border.

In spite of the political weakness of Poland, the great Mongol-Tatar invasion, and the menace from Germany, this age was one of great importance to the development of Poland. In the process of decentralization, each province was able to assert its own individuality, helping its prince and bishop to enlarge its capital city and to intensify their efforts to develop the resources of its small territory. The petty princes and great landowners were able to imitate Western Europe by encouraging the immigration of German peasants, townsmen, and artisans, who helped them to raise the level of economic life. The ideal of the prince, especially in Silesia, was *melioratio terrae* (the improvement of his land), to achieve which he was prepared to sacrifice both part of his own sovereign power and vague national ideals. This lack of a Polish patriotism resulted in the loss to Poland of some areas: Lower Silesia, the district of Lubusz on the lower Oder, and western Pomorze were gradually colonized by Germans. But the economic and cultural advance of the country as a whole was worth the sacrifice. The community thus strengthened was able to maintain its ethnical frontier in spite of political disaster for six centuries.

In most of Poland the Germans were ultimately absorbed. The princes further reduced their sovereign power by the granting of charters to different groups and individuals. The Jews, whom crusading zeal had expelled from nearly every country, were granted the right to settle in Poland, to maintain their own schools, and to practise their religion. For the Poles they were skilled middlemen who made an important contribution to the economic life of the country but who were never absorbed as the Germans were and hampered the formation of a Polish middle class. The achievements of the period of division, in spite of its difficulties and weaknesses, can be appreciated through a comparison of the low social and economic situation in the 12th century with the resources available to the revived monarchy after 1305, whereby the rulers were able to reunite the divided principalities and to preside over the rapid development of a state that had no need to copy the social and economic life of its neighbours.

2. Wladyslaw I, 1314–33.—The idea of reuniting the Polish principalities in one state first appears in the experiments of the princes of Silesia, especially in those of Henry I the Bearded (1201–38). These princes failed partly because they gradually succumbed to the attraction of German civilization and joined the empire under Czech auspices. Przemysl II of Great Poland actually assumed the royal title in 1295; but the real task of reunion was undertaken, at a time when Poland had come under the rule of Czech kings, by the hard-fighting Wladyslaw Lokietek (the Short; *see* WLADYSLAW) of Kujavia. The idea was supported by the gentry and the ecclesiastical leaders. These men had represented for a long time the links that bound Poles together and led the enlightened magnates who realized that a divided Poland would suffer extinction at the hands of such powerful neighbours as Bohemia, Brandenburg, Hungary, and the Teutonic Order.

Wladyslaw cleverly availed himself of the support of Hungary and of the traditional protection of the Holy See. After occupying Little Poland in 1305 and Great Poland in 1314, he was crowned king of Poland in 1320 as Wladyslaw I. He had many disappointments: the Teutonic Order seized Pomorze in 1308; his country long continued to suffer from the raids of the pagan Lithuanians; and he never reigned over Silesia or Mazovia, which preferred to do homage to John of Bohemia. But he held his own against the

order in the Battle of Plowce (1331), strengthened his position by his diplomatic friendship with Hungary (which was sealed in 1320 by his daughter Elizabeth's marriage to the new Angevin king Charles I), and ended for a time the Lithuanian raids by marrying his son Casimir to Anne (Aldona), daughter of Gediminas in 1325. Wladyslaw died in 1333.

3. Casimir III the Great, 1333–70.—Unlike his father, Casimir succeeded to a kingdom already in being and was a man of peace. A realist and a shrewd diplomat with a zest for the Latin culture that he learned at the court of his sister in Hungary, he was ready to make great sacrifices to secure the independence, unity, and prosperity of his kingdom. Happily for Poland the disunity of Germany, the weakness of Russia, and the death of the last great khan of the Tatars lessened the dangers on the western and eastern frontiers. Poland had to face in the south the powerful kingdom of Bohemia, whose king in 1355 was crowned Holy Roman emperor as Charles IV, and in the north the great military strength of the Teutonic Order. Basing his foreign policy on a close alliance with Hungary, Casimir was content to allow Charles IV, another lover of peace, to hold Silesia, and limited his claim to Pomorze and the border districts held by the order. As compensation for this loss of Polish territory, he found himself able by inheritance and diplomacy to annex in 1349 the principality of Halicz (*see* GALICIA) and to begin that policy of conciliation with the Lithuanian princes which was to bring such important results later on. His own prestige grew abroad, and he made Poland a full member of the European community.

By gaining for Poland a long period of peace and security, Casimir was able to make great changes in the internal relations of the country. He codified the laws of Great and Little Poland and succeeded in persuading these two rival provinces to cooperate, while the local officials of Little Poland became national ministers. The princes of Mazovia were persuaded to acknowledge Casimir as their king. He acquired great wealth, reformed the currency, and introduced Western methods in town and country. He befriended the Jews, improved the position of the peasants, and encouraged the immigration of Germans and Armenians, so that the cities grew in size and prosperity, especially Cracow and Lwow (Lvov). He was a great builder and was said to have "found a country of wood and left a country of stone." The administration was made more efficient, and it was mainly to train young men in law that Casimir founded the University of Cracow in 1364. He encouraged learning and was able, through the Italian influences at the court of Hungary and the French connections of Prague, to raise the level of learning among the Poles to Western European standards. By his foresight, his patience, and genius for creation and adaptation, this great statesman made possible the strong and prosperous position of the Polish kingdom during his lifetime and its great development in the next two centuries.

4. Louis I of Hungary, 1370–82.—Having no sons, Casimir III bequeathed his kingdom to his sister Elizabeth's son the Angevin Louis I of Hungary (1370–82), already one of the leading rulers of central Europe, who continued the cooperation of his two realms in the spirit of his predecessor. Like Casimir, he left no sons, and the future of central Europe depended to some extent on the fate of his two daughters. After an interregnum of two years the Poles accepted his younger daughter Jadwiga as their queen (1384–99) and consummated the efforts of Casimir III to conciliate the pagan rulers of Lithuania by arranging the marriage of Jadwiga to Jagiello, grand prince of Lithuania, who became king of Poland as Wladyslaw II (1386–1434).

5. Social and Constitutional Development, 1138–1384.—The social structure of the Polish state at the time of the dynastic union with Lithuania was very different from what it had been under the early kings. In the period of division there had grown up around each prince a class of ecclesiastical and lay magnates whose function was at first to advise him and later to share with him the government of his principality. In addition to this privileged class, the general mass of the gentry, organized in their clans, each with its coat of arms and slogan, was becoming conscious of its own importance as a social and political element in the country. As the prince gradually lost his monopoly of political

and legal power by the grant of charters to various groups, this body, which came to be called the *szlachta*, began to share political privileges with the magnates. The extinction of the Piast dynasty gave them the opportunity by the Pact of Koszyce (Kosice) in 1374 to obtain from Louis a number of privileges, the *magna carta* of Poland. The chief of these was the right to pay no taxes beyond a certain sum, unless they had expressly consented to them. During the period of division the church, which had established its position at the Congress of Leczyca in 1180, played a leading part, not only in the social and moral life of the community but also as a factor of unity among the numerous principalities. Strengthened by the Gregorian reforms, it obtained judicial and financial autonomy as well as independence from the princes. The inhabitants of the towns had received charters mainly under Magdeburg law to encourage the settlement of both Poles and Germans. Besides Wrocław and Poznań, the two great cities Cracow and Lwów grew to prosperity on the great Eastern trade route. These towns, though at first largely foreign in race, became integral members of the community, able to aid and to advise the prince and to attain political importance. The peasants, with the rise of the gentry, lost in social standing but gained economically by the tenant system, developed to a great extent mainly during the reign of Casimir III—a situation that only slowly worsened as serfdom grew up a century later. From the small body of educated men who made the court of Bolesław III superior to that of the early kings (with the famous Otto, later bishop of Bamberg, and the anonymous scholar who wrote the first history of Poland), through the spread of Western social and moral ideas (at first chiefly by the Cistercians) to the writing of a real historical work by Wincenty Kadłubek (d. 1223), the great progress of learning in the Polish community can be followed. The great problem of the Poles was to seek and assimilate Western institutions and ideas while retaining and cherishing their own native civilization. They were forced to learn mainly from the Germans. But the political exploitation of this position by the latter led to the rise of strong anti-German feeling and to the practice of seeking models in Italy, France, or the Low Countries in preference to Germany. The union of Poland and Lithuania was a mortal blow to the position of the Teutonic Order, the greatest German power on the Polish border; and it opened vast new territories for political and economic development by the strengthened gentry and nobility.

B. THE JAGIELLON DYNASTY

1. Jadwiga and Władysław II Jagiello.—The magnates of Cracow, Casimir III's pupils and successors, were able to instruct the girl queen and the pagan king in the arts of government. One of the first acts of the new king was to receive Christianity for himself and his people. The Lithuanians, unlike the Ruthenians of their principality, who were Orthodox, joined the Roman Catholic Church. So the Poles gained by peaceful agreement what the Teutonic Order had sought by violence for a century and failed to win: the conversion of the last great body of pagans in Europe.

The very reason for the existence of the order had gone, and it would have to struggle to preserve its territories, which included Pomorze and the whole of Prussia. But the settlement was delayed for some time, partly because of Jadwiga's religious scruples against fighting a crusading body, and partly because Władysław Jagiello had to solve the difficult problem of Lithuania, where he had a rival in his cousin Vytautas (Witold). The order exploited this situation so adroitly that the king was forced to recognize Vytautas as grand prince of Lithuania. This arrangement was successful for a time, and in 1409 the aggression of the order provoked the two cousins to join their forces against their common enemy. Advancing into Prussia they completely defeated the Knights in the great Battle of Grunwald (*q.v.*) in 1410. Unfortunately, though the victory was followed by the union of Horodlo (1413), which established in Lithuania institutions based on those of Poland, the two cousins did not always agree; and Poland was exposed in the south to the hostility of Sigismund of Bohemia, who had succeeded to the possessions of Louis of Hungary in 1387

and to the German kingdom in 1410.

Jagiello lost his wife Jadwiga in 1399 and remained without male issue by his next two wives; but his fourth, whom he married in 1422, the Lithuanian princess Zofia of Alsenai (Holszanska) gave him what Poland needed: two sons. Throughout his long reign he continued to collaborate amicably with the Polish leaders or, occasionally, to oppose them, knowing well that the union with Lithuania depended on his own person. As a cautious ruler he supported the Czech Hussites, but refrained from interventions abroad. He suffered great anxiety from the ambitions of Vytautas, who was a great warrior and statesman and planned to conquer the Tatars and to annex Moscow. Beloved by the Lithuanian people, Vytautas died in 1430. Władysław Jagiello died in 1434, after a reign of 48 years, at a great age. He was, like most of his family, a prudent, tolerant, and tenacious ruler, and he founded a dynasty that was to be one of the greatest in Europe.

2. Władysław III, 1434–44.—Jagiello was succeeded by his ten-year-old son Władysław III, the chief position in the realm being held by the most eminent of the Cracow magnates, Zbigniew Oleśnicki (*q.v.*), bishop of Cracow and one of the previous king's chief advisers, who became first Polish cardinal. Oleśnicki had to deal with a number of urgent problems: the spread of Hussitism among the gentry; the threat to European civilization from the Turks on the Danube; the possibility of the recovery of Silesia from the Czechs and of Pomorze from the Teutonic Order; and the dangerous rise of rebellion in Lithuania among the Orthodox Ruthenians. A highly cultured scholar, a great orator and diplomat, he played a leading part in the Council of Basel. The Lithuanian rebels, though supported by the master of Livonia (the Knights of the Sword had been amalgamated with the Teutonic Order in 1237), were decisively defeated in 1435 near Wilkomierz (Ukmerge).

A churchman, Oleśnicki was, like Queen Jadwiga, prepared to conciliate the Teutonic Order and to concentrate the national forces against the heretical Czechs (so as to recover Silesia) and against the Turks in the south. He failed in the first project, and his great crusade, which involved securing the throne of Hungary for Władysław III (who thus became Ulászló I of Hungary), was brought to a disastrous end by the defeat at Varna (1444), where Władysław was killed. Until his death was certain, Poland remained without a ruler for three years (1444–47). Then Władysław II Jagiello's second son, Casimir, who had made himself popular in Lithuania, ascended the Polish throne.

(A. B. Bo.; A. Wv.)

3. Casimir IV, 1447–92.—The difficulties which confronted Casimir were great. He recognized not only the vital necessity of the maintenance of the union between the two states but also the fact that the chief source of danger to the union lay in Lithuania. For political reasons, during the earlier years of his reign, Casimir was obliged to reside for the most part in Lithuania, and his interest in that principality was always resented in Poland, where, to the very end of his reign, he was regarded with suspicion. In particular, he could never rely on adequate Polish support in the struggle with the Teutonic Order.

The struggle assumed a new form in 1454, when Casimir accepted the suzerainty offered to him by the Prussian league, which had repudiated the authority of the order and needed a protector. The acquisition of the Prussian lands was vital to the existence of Poland. It meant the command of the principal rivers of Poland, the Vistula and the Niemen, and the acquisition of a seaboard with its corollaries of sea power and commerce. Yet, except in the border province of Great Poland, which was interested commercially, the king received little support, military or financial, and it was only with his victory at Zarnowiec (Sept. 17, 1462) that he obtained any decisive success against the order. The war was ended in 1466 by the second Treaty of Toruń (Oct. 19), by which Poland recovered the provinces of Pomorze, Chełmno, and Michalów, with the bishopric of Warmia (Ermland), numerous cities and fortresses, including Malbork (Marienburg), Elbląg (Elbing), Gdansk (Danzig), and Toruń. The territory of the order was now reduced to Prussia proper, embracing, roughly speaking, the district between the Baltic, the lower Vistula, and the lower Nie-

men, with Königsberg (modern Kaliningrad) as its capital. For this territory each grand master within nine months of his election was in the future to render homage to the Polish king. The regained part of Pomorze, now called Royal Prussia, became a largely autonomous Polish province, and Poland had again acquired a seaboard.

The whole foreign policy of Casimir IV was influenced by the Prussian question. At the beginning of the war both the empire and the papacy were against him. He therefore allied himself with George of Podebrady, whom the Hussites had placed on the throne of Bohemia. On the death of George (1471), Casimir's eldest son, Vladislav (*i.e.*, in Polish, Władysław), was elected king of Bohemia despite the determined opposition of Matthias I Corvinus (Mátyás Hunyadi), the king of Hungary, who thenceforward deliberately set about traversing all the plans of Casimir. He encouraged the Teutonic Order to rebel against Poland; he entertained at his court anti-Polish embassies from Moscow; he encouraged the Tatars to ravage Lithuania; he thwarted Casimir's policy in Moldavia. His death in 1490 came, therefore, as a distinct relief to Poland, and all danger from the side of Hungary was removed when Vladislav, already king of Bohemia, was elected king of Hungary also as Ulászló II.

It was in the reign of Casimir IV that Poland first came into direct collision with the Turks. The Jagiellons, as a rule, prudently avoided committing themselves to any political system which might irritate the still distant but much-dreaded Turks; but when their dominions extended so far southward as to embrace Moldavia the observance of a strict neutrality became exceedingly difficult. Poland had established a sort of suzerainty over Moldavia as early as the end of the 14th century, but at best it was a loose and vague overlordship which the hospodars repudiated whenever they were strong enough to do so. The Turks themselves were too much occupied elsewhere to pay much attention to the Danubian principalities till the middle of the 15th century, and it was not till 1484 that they became inconvenient neighbours to Poland. In that year a Turkish fleet captured the strongholds of Kilia and Akkerman, commanding, respectively, the mouths of the Danube and Dniester. This aggression seriously threatened the trade of Poland, and induced Casimir IV to accede to a general league against the Porte. In 1485 the Polish king, at the head of 20,000 men, proceeded to Kolomyia on the Pruth, where he received the homage of Prince Stephen of Moldavia; and the hostilities with Bayazid II were suspended by a truce (1489). During the remainder of Casimir's reign the Turks gave no trouble.

Casimir IV strengthened the royal authority by supporting the gentry against the nobles and by obtaining from the Holy See the right of appointing bishops.

4. John Albert and Alexander.—The death of Casimir was followed by the temporary separation of Poland and Lithuania and by a strong but short-lived aristocratic reaction in Poland. Casimir's third son, John Albert, was elected king of Poland, and his fourth son, Alexander, became grand prince of Lithuania.

The short reign of John Albert (1492–1501), a friend of the gentry, was occupied by contention with the Teutonic Order, which evaded paying homage to the king; and by an unsuccessful Polish expedition against Moldavia.

On the death of John Albert, Alexander succeeded him as king (1501–06), and the union of Poland and Lithuania assumed a more definite character, the Senate of each country agreeing that in the future the king of Poland should always be grand prince of Lithuania. The acquiescence of Lithuania was essentially the result of a new danger which had arisen in the East. Until the accession of Ivan III in 1462 Moscow had been a negligible factor in Polish politics. During the earlier part of the 15th century the Lithuanian princes had successfully contested Muscovite influence even in Pskov and Great Novgorod. But since the death of Vytautas the military efficiency of Lithuania had sensibly declined, and the natural attraction of the Orthodox Greek element in Lithuania toward Moscow threatened the integrity of the principality. During the reign of Alexander, who was too poor to maintain any adequate standing army in Lithuania, the Muscovites and Tatars ravaged the whole country at will and were prevented from con-

quering it altogether only by their inability to capture the chief fortresses. In Poland, meanwhile, Alexander had practically surrendered his authority to an incapable aristocracy till 1505, when the gentry led by the Laski family extorted a constitution based on the principle *Nihil novi* ("No innovations"). The dependent states of Prussia in the north and Moldavia in the south made strenuous efforts to break away.

5. Sigismund I, 1506–48.—When Sigismund I, the energetic but extremely cautious younger brother and successor of Alexander, began his reign, the state was threatened by its neighbours and needed internal reforms. The Teutonic Order refused to pay homage and was preparing war; there was a latent hostility between Moscow and Lithuania; and the Holy Roman emperor Maximilian I was trying to coordinate the actions of both those enemies against Poland. Tatar and Moldavian raids started simultaneously from the southeast, followed soon by a Turkish advance. The state needed, in particular, the means of increasing expenditure and a standing army. Renewed attempts at reforms failed because of the opposition of the gentry and its representatives in the *sejm*, or diet. In 1537, near Lwow, the assembled gentry almost threatened open mutiny. Despite those difficulties the internal structure of the state was gradually strengthened, the economy was developed, fiscal resources increased, and the strongholds of Kamieniec and Bar were fortified.

The Vienna agreement (1515) with the emperor Maximilian contributed to the breakdown of the anti-Polish coalition by allowing for Habsburg influence in Hungary and Bohemia. At the same time Konstanty Ostrogski's victory over the Muscovite armies at Orsha in 1514 enabled the Poles to give closer attention to the problem of Prussia and the Teutonic Order. Sigismund began war in 1519 and won some success against the order; but its grand master Albert (*q.v.*), a member of the house of Hohenzollern, became a Lutheran and created a secular duchy known as Ducal Prussia (1525). Sigismund did not achieve the incorporation of the order's lands into Poland, but the new duchy, which was the first Protestant state in this part of Europe, became autonomous under allegiance to the Polish crown.

The most important political event in Eastern Europe during the reign of Sigismund was the collapse of the ancient Hungarian monarchy at Mohács in 1526. After the death of King Louis II in the battle, the archduke Ferdinand (later Holy Roman emperor as Ferdinand I) and John Zápolya, voivode of Transylvania, competed for the vacant Hungarian crown, and both were elected almost simultaneously, Ferdinand also securing election to the kingdom of Bohemia. In Poland Zápolya's was the popular cause, and he also found powerful support among the gentry and in the influential and highly gifted Laski family, represented by the Polish primate Jan Laski the Elder and his nephews (*see* LASKI).

Polish policy toward Hungary, based on noncommitment, was expressed in attempts at mediation between the two competitors, while care was taken not to provoke the Turks, whose settlement in Hungary it was desired to prevent. Sigismund I was closely connected with the Zápolya family through his first wife Barbara Zápolya (d. 1515), and later through the marriage of his daughter Izabella to John Zápolya (1539). On the other hand he reckoned also with the Habsburgs, treating with the emperor Charles V as well as with Ferdinand, to whose daughter Elizabeth he married his son Sigismund Augustus in 1543; but he attempted to check the Habsburgs by his ties with France (1524). His treaty with Turkey (1533), however, gave Poland no protection from predatory raids by the Moldavians or by the Tatars. The Moldavians, defeated by Jan Tarnowski at Obertyn (1531), made peace; but the safeguarding of the frontier from the Tatars was mainly achieved by bribes and by turning them against Muscovy.

The incorporation of Mazovia into the royal territory (1526) was a great success for Sigismund I's internal policy. But the last years of his long reign were affected by his illness and by the constant interference of his second wife, Bona Sforza, in Polish affairs. (R. N. B.; A. Wv.)

6. Sigismund II Augustus, 1548–72.—Already in the 15th century the University of Cracow had brought forth humanist scholars of European repute and begun to attract distinguished

lecturers and numerous students from abroad. Because of Sigismund I's marriage to the Milanese Bona Sforza (1518), the royal court in Cracow became the home of the highest Renaissance art of Italy, and the royal castle on Wawel Hill, rebuilt by Italian architects and their Polish disciples, became one of the finest monuments of Renaissance style north of the Alps. Under Sigismund II the third great spiritual factor of the age, next to humanist scholarship and Renaissance art—the doctrine of the Reformation—entered potently into Poland's intellectual life, uniting with Italian culture on the common ground of literature and helping to produce the first great age of Polish poetry and prose. There followed the clash between the New Learning and the strong tradition of Poland's chivalrous Catholicism; the difficulties with the Scandinavian powers and the rising empire of the Moscow tsars; the dilemma produced between the evolution of the Polish parliamentary system and the Renaissance tendency toward the strengthening of the central government. Even a king of genius could be only partially successful in coping with all these tasks, and the reign of Sigismund II, in many respects one of the most brilliant in Polish annals, left many problems unsolved.

Reformation and Counter-Reformation.—The new king having shown his temper by marrying a lady of the noble house of Radziwill without asking for the opinion of the Senate, the reign began in a storm of demands for constitutional guarantees to secure the parliamentary "gentry democracy" against the powers of the crown and the nobility. The king resolutely allied himself with Austria abroad and with some bishops and nobles at home, against a threatened revolt of the gentry and the intrigues of his mother. In doing so, he had to take the bishops' side in the issue between the Reformation and Catholic orthodoxy, and he affirmed this by an edict against heresy in 1550. But this act only opened up the long-maturing dispute about the creation of a national church after the recent example of Henry VIII of England. The king, a man of enlightened mind, the first Polish monarch who habitually used the vernacular language instead of Latin at public functions, showed in many ways a sympathetic understanding for the tendencies of the new era. The influence of the Bohemian Hussite movement of 100 years before combined with nascent modern nationalism to inspire definite programs for a Reformed Polish Church with Polish ritual, independent of Rome, and with a priesthood subject to government authority. The large Greek Orthodox element among the citizens of the eastern provinces of the monarchy furnished an additional stimulus, which gave strength to such demands as that for the abolition of clerical celibacy in the Lutheran fashion. The bishops resorting to highhanded measures of repression, the *sejm* of Piotrkow in 1552 voted, at the king's own suggestion, the suspension of clerical courts for a year. This was extended afterward and solemnly renewed by another *sejm* in 1555, during which the gentry required Masses in Polish and the communion to be administered in two kinds. A religious interim of about ten years followed, during which Protestantism in Poland flourished.

Presently reformers of every shade of opinion, even those who were tolerated nowhere else, poured into Poland, which speedily became the battleground of all the sects of Europe. Soon the Protestants became numerous enough to form ecclesiastical districts of their own. The first Calvinist meeting in Poland was held at Pinczow in 1550. The Bohemian Brethren, expelled from their own country, ultimately coalesced with the Calvinists at the Synod of Kozminek (August 1555). In the *sejm* itself the Protestants were absolutely supreme and generally elected a Calvinist to be their marshal. The king, however, perceiving a danger to the constitution in the violence of the gentry, not only supported the bishops but quashed reiterated demands for a national synod. The *sejm* of 1558–59 indicates the high-water mark of Polish Protestantism. From this time forward it began to subside, gradually but unmistakably, chiefly because of the division among the reformers themselves. From the chaos of creeds resulted a chaos of ideas on all imaginable subjects, politics included. The anti-Trinitarian heresy proved to be the chief dissolvent, and from 1560 onward the relations between the Lutherans and the Calvinists were fratricidal rather than fraternal; Jan Laski the Younger

vainly strove to unite all Polish Protestants round the Helvetian standard, and a federation of all Poles of the Reformed faith—the "Concord of Sandomierz" (1570), predominantly Calvinist in character—met resolute Lutheran opposition and led to nothing.

While the strong individualism of the Polish national character thus thwarted all endeavours at Protestant consolidation, political factors told in favour of Catholicism; so did presently the wiser policy of Rome. Pope Pius IV, unlike his predecessor, adopted a conciliatory attitude toward the Polish crown in the matter of disputed appointments of bishops. The new bishops were holy and learned men, very unlike the creations of Queen Bona, and capable of reorganizing the scattered and fainthearted Catholic forces in the land. From one of the ablest of them, Giovanni Commendone, the king, at the *sejm* of 1564, accepted the book of the decrees of the Council of Trent. In 1565 the Jesuits, the vanguard of the Catholic Counter-Reformation, appeared in Poland. At their best, the various forms of Protestantism had never won more than a scanty noble and intellectual elite of the nation; they had never taken root among the peasantry or the petty bourgeoisie—except in the cities of Royal Prussia.

Livonia.—In the middle of the 16th century the Order of the Knights of the Sword (the Livonian Order), whose territory embraced Estonia, Livonia, Courland, and the islands of Dagö and Oesel, was tottering. All the Baltic powers were more or less interested in the apportionment of this vast tract of land, whose geographical position made it not only the chief commercial link between East and West but also the emporium whence the English, Dutch, Swedes, Danes, and Germans obtained their grain, timber, and most of the raw products of Lithuania and Moscow. Poland and Moscow as the nearest neighbours of this moribund state, which had so long excluded them from the sea, were vitally concerned in its fate. After an anarchic period of suspense, lasting from 1546 to 1561, during which Sweden secured Estonia while Ivan IV, the Terrible, fearfully ravaged Livonia, Sigismund II, to whom both the master of Livonia and the archbishop of Riga (brother of the duke of Prussia) had appealed more than once for protection, at length intervened decisively. At his camp before Riga in 1561 the last master, who had long been at the head of the Polish Party in Livonia and had embraced Protestantism, and the archbishop of Riga gladly placed themselves beneath Sigismund's protection, and by a subsequent convention signed at Wilno (Vilnius) on Nov. 28, 1561, Livonia was incorporated with Lithuania partly in the same way as Royal Prussia had been incorporated with Poland 95 years previously; and Courland, as a new Protestant duchy, became a fief of the Polish crown, with local autonomy and freedom of worship. (See also LITHUANIA.)

Union with Lithuania, 1569.—The danger to Lithuania, revealed in the Baltic wars with Ivan the Terrible, as well as the requests on these matters of the Polish *sejm*, must have convinced Sigismund II of the necessity of preventing any cleavage in the future between the two halves of his dominions. A personal union under one monarch had proved inadequate. A further step must be taken—the two independent countries must be transformed into a single state. The principal obstacle was the opposition of the Lithuanian magnates, who feared to lose their dominance in the grand principality if they were merged in the *szlachta* ("gentry") of the kingdom. When things came to a deadlock in 1564, the king tactfully intervened and voluntarily relinquished his hereditary title to Lithuania, thus placing the two countries on a constitutional equality and preparing the way for fresh negotiations. The death in 1565 of Mikolaj Radziwill (the Black), the chief opponent of the union, still further weakened the Lithuanians, but the negotiations, reopened at the *sejm* of Lublin in 1569, at first also led only to rupture. Then Sigismund executed his master stroke. Suddenly, of his own authority, he formally incorporated Podlasia, Volhynia, and the province of Kiev into the kingdom of Poland, whereupon deputies from these provinces took their places on the same benches as their Polish brethren. The hands of the Lithuanians were forced. Even a complete union on equal terms was better than mutilated independence. Accordingly they returned to the *sejm* and the union was unanimously adopted on July 1, 1569. Henceforth the kingdom of

Poland and the grand principality of Lithuania were to be one inseparable and indivisible body politic; all dependencies and colonies, including Prussia and Livonia, were to belong to Poland and Lithuania in common. The retention of the old duality of dignities was the one reminiscence of the original separation; it was not abolished till 1791, four years before the final partition of Poland.

The union definitely shifted Poland's political centre of gravity eastward; it created a common interest in the Russian menace to the long and naturally defenseless eastern frontier and in the millions of Greek Orthodox people living in the eastern borderlands. Warsaw was appointed one of the meeting places of the joint *sejm*, thus preparing the transfer of the capital from Cracow to Warsaw. The union was the last great historical act of the Jagiellon dynasty; it put the coping stone to the structure of a monarchy which, with growing consolidation, seemed to bear in it the promise of empire.

7. Political Development, 1384-1572.—Simultaneously with the transformation into a great power of the petty principalities which composed ancient Poland, another and equally momentous political transformation was proceeding within the country itself.

The origin of the Polish constitution is to be sought in the *wiece*, or councils, of the Polish princes during the period of division. The privileges conferred upon the magnates of whom these councils were composed, especially upon the magnates of Little Poland (who brought the Jagiellons to the throne, directed their policy and grew rich upon their liberality), angered the less-favoured gentry or *szlachta*, who, toward the end of the 14th century, combined for mutual defense in their *sejmiki* or local diets.

The first *sejm* known to legislate for all Poland was that of Piotrkow (1493), summoned by John Albert to grant him subsidies; but its decrees were to have force for only three years. John Albert's second *sejm* (1496), after granting subsidies, the burden of which fell entirely on the towns and peasantry, passed a series of statutes benefiting the nobility at the expense of the other classes—especially the peasants. These were followed by others of the same kind under his successor, Alexander. Nevertheless, so long as the Jagiellon dynasty lasted, the political rights of the cities were jealously protected by the crown against the usurpations of the nobility. The burghers of Cracow, enlightened economists, supplied Sigismund I with his most capable counselors during the first 20 years of his reign (1506-26). Sigismund's predecessor, Alexander, had been compelled to accept the statute *Nihil novi* (1505), which became the basis of the parliamentary rule that new laws could be introduced only by a resolution of the *sejm*. Under Sigismund I some of the royal prerogatives were recovered, but in his later years, after the mutiny of 1537, the influence of the gentry returned. The Polish parliamentary system, vesting supreme powers in the two houses of the *sejm*, was an established fact.

Sigismund II knew that only a strengthening of the central authority could save the state. His endeavours to maneuver his way between the two rival powers of the magnates and the lesser gentry were, on the whole, successful. A patriotic party of gentry democrats arose, veiling its program of democratic reforms under the conservative watchword of the "execution of the laws," dealing further legislative blows against the nobles and the Catholic hierarchy, and demanding fiscal, military, and judicial reforms, complete union with Lithuania, and religious freedom. The king at first sided with the great nobles against the "executionists," but the Livonian War forced him to make an alliance with the latter to curtail the power of the magnates by a repeal of former royal grants of land and by the imposition of a tax on all tenants of crown lands for the maintenance of the standing army (1562-63).

Poland's favourable economic situation facilitated not only internal reforms and international activity, but also cultural development, especially the rise of national literature, science, and fine arts. The rising demand in Western Europe, for agricultural produce, particularly of grain, and a rise in its prices, contributed to the wealth of the countryside; and the towns also grew richer and more numerous despite their limited role in political and social life.

C. THE ELECTIVE KINGS

The childless Sigismund II Augustus died suddenly in 1572. Fortunately for Poland, the political horizon was unclouded. Domestic affairs, however, were in bad condition. The union of Lublin, barely three years old, was anything but consolidated, and in Lithuania it continued to be unpopular. Worst of all, there was no recognized authority in the land to curb its jarring centrifugal political elements. Civil war was averted at the last moment, and a national convention assembled in Warsaw in April 1573 for the purpose of electing a new king. Five candidates for the throne were already in the field. Lithuania favoured the Russian tsar Ivan IV. In Poland the bishops and most of the Catholic magnates were for an Austrian archduke, while the strongly anti-German *szlachta* were inclined to accept almost any candidate but a German. It was easy, therefore, for the adroit and energetic French ambassador, Jean de Lasseran Massencome de Monluc, bishop of Valence, to procure the election of the French candidate, Henry de Valois, duc d'Anjou. Well provided with funds, he speedily bought over many of the leading magnates, but he was regarded askance by the Protestants. The religious difficulty in Poland, however, had meanwhile been adjusted to the satisfaction of all parties by the Compact of Warsaw (Jan. 28, 1573), which granted absolute religious liberty to all non-Catholic denominations without exception—a far more liberal measure than the Germans had made in the religious Peace of Augsburg 18 years before. Finally, on April 11, 1573, the election *sejm* met in Warsaw, elected Henry king of Poland.

1. Henry de Valois, 1573-74.—The election had been preceded by a reform of the constitution, which resulted in the famous "Henrician articles" converting Poland from a limited monarchy into a republic with an elective chief magistrate. The king was obliged to convoke the *sejm* every two years; and in the periods between sessions he was to be advised by a group of senators. Should the king fail to observe any one of these articles, the nation was *ipso facto* absolved from its allegiance. Whatever its intrinsic demerits, the disastrous fruits of this reform were largely caused by the geographical position of Poland, and it must be remembered that Poland alone with England preserved the tradition of parliamentary government in the increasing absolutist Europe of the time. Beside constitutional restrictions, the new king had to undertake certain personal obligations called *pacta conventa*.

Henry reached Poland on Jan. 25, 1574, and was crowned in Cracow on Feb. 21. His reign lasted 14 months. The tidings of the death of his brother Charles IX of France determined him to exchange a thorny for what he hoped would be a flowery throne, and at midnight on June 18, 1574, he literally fled from Poland to become Henry III of France. The king's escape caused dismay, and trouble broke out while the country was awaiting his return; finally an *interregnum* was proclaimed. In November 1575 the senate elected the emperor Maximilian II to the throne; but the gentry democracy, at the suggestion of its new leader Jan Zamoyski, chose a prince of Transylvania, Stephen Báthory, assigning him as husband to Anne, the last surviving princess of the Jagiellon dynasty, and enforced this election by arms.

2. Stephen Báthory, 1575-86.—With the insight of a born statesman Báthory focused his energy on two vital objectives: the maintenance of Poland's access to the sea by way of Gdansk (Danzig), and the defense of its newly gained further seaboard in the northeast against the rising power of Moscow. Gdansk, on Báthory's election, began to intrigue against him with the emperor Maximilian (until his death in October 1576) and with Russia and Denmark. In spite of a deplorable lack of understanding on the part of the Polish gentry for the issue at stake, Báthory, who had throughout the able and strenuous support of his chancellor Zamoyski, conducted a campaign against Gdansk both by land and sea and finally enforced its complete submission to his rule.

Before peace was made with Gdansk, Ivan the Terrible had raided Livonia once more. Báthory, using infantry rather than cavalry and calling peasants and burghers to arms together with the gentry, achieved in the operations against Russia the great military triumphs of his reign. In three successive expeditions

he pushed his way northeastward as far as Pskov, and the tsar was willing enough to obtain the pope's intervention by a promise of making Russia Catholic. As a result of Báthory's victories, Poland pushed Russia entirely away from the Baltic for a long time and regained sway over nearly the whole of Livonia.

Báthory, a skilled politician, knew how to make the most of the important minority groups, the Ukrainian Cossacks and the Jews. The Cossacks were largely runaway serfs, who had organized themselves into a sort of military republic on the vast and scantily inhabited plains of the Ukraine or "borderland," stretching from the southeast of the monarchy toward the Black Sea along the Dnieper River. The Cossack community had been drawn into the Polish military system under Báthory's predecessors by registration and pay and had already been granted exemption from taxation, as well as their own jurisdiction. Báthory, who needed them for his Russian wars, confirmed and enlarged these privileges. His successors used the Cossacks against the Russians, Turks, and Tatars; but soon the Cossacks were to be a factor of trouble for Poland, not without serious errors of policy on the Polish side. (See also UKRAINIAN SOVIET SOCIALIST REPUBLIC: *History*.)

The privileges which the Jews had obtained from former kings were augmented; from Báthory's day until 1764 the Polish Jews had a Parliament of their own, meeting twice a year, with powers of taxation. It was also chiefly in the interest of the Jews that Báthory restricted, by special edict, the trading rights of Scottish pedlars who were very numerous in Poland at the time. Among other domestic measures, Báthory reformed the Polish judicial system by the creation of a Supreme Court of Appeal for civil and penal cases, and he founded, in 1579, the University of Wilno as the first institution of higher education in Lithuania.

For internal affairs Báthory knew how to strengthen his position and authority, despite the existing restrictions on royal power. Hungarian tradition and relations with the Habsburgs and with the Holy See induced him to plan a great expedition against the Turks. But this project was carried with Báthory to his grave on his sudden death in 1586.

3. Sigismund III, 1587-1632.—The Vasa period of Polish history, which began with the election of Sigismund, son of John III of Sweden and of Sigismund I's daughter Catherine, was one of last and lost chances. The collapse of the Muscovite tsardom and the submersion of Germany by the Thirty Years' War presented Poland with an unprecedented opportunity of consolidating, once for all, its hard-won position as the dominating power between central and eastern Europe; it might even have wrested the best part of the Baltic littoral from the Scandinavian powers and pushed Russia back. That this was not achieved was partly caused by the opposition of the *szlachta*, who persisted in a defense of "republican liberty" at the very time when the need of a strong central executive was more urgent than ever.

But other grave causes of failure were not wanting. One of them consisted in the very personality of the new foreign-bred king: the tenacity with which he clung to his hereditary rights to the Swedish crown involved Poland in unnecessary wars with Sweden at most inopportune times; and his bigoted devotion to the cause of Catholicism introduced a new spirit of religious fanaticism and persecution into the atmosphere of a country hitherto distinguished for toleration, while the same bigotry served Poland's interests very ill abroad. Poland's greatest statesman of the time, Jan Zamoyski, discovered in the earliest years of the reign that the king, who had married Anna, daughter of the Habsburg Charles of Styria, was willing to surrender the crown of Poland to an Austrian archduke and to return to his native Sweden in order to bring it back to the Catholic fold. Zamoyski, who had himself placed Sigismund on the throne by conquering a rival Austrian candidate, was naturally indignant, and the whole disgraceful affair of the king's secret negotiations with Austria culminated in his having to answer the charges of a special "diet of inquisition" (1592)—the first time that the prestige of the crown in Poland was exposed to such an ordeal.

The Uniate Church.—It was only where the expansion of Catholicism served the interests of the Polish state that Zamoyski saw eye to eye with the king's Catholic zeal. Thus, he became in-

EDMUND RUPIECKI, WARSAW

CASTLE SQUARE IN WARSAW

In the centre is the Column of King Sigismund III Vasa which was first erected in 1644 and re-erected after World War II. At left is St. Anne's Church which dates from 1454. In the upper right is the Palace of Culture and Science which was given to the people of Poland by the U.S.S.R. in 1955

strumental in creating, at the Synod of Brzesc in 1596, the Uniate Church as a halfway house for those of the republic's Greek Orthodox citizens who were willing to recognize the supremacy of Rome but desired to preserve their accustomed Eastern ritual and Slavonic liturgy. The Uniate Church served the purpose of drawing a large section of the population of the eastern border provinces out of the orbit of Moscow and into that of Polish influences; but by the antagonisms which soon began between Uniates and non-Uniates, it became in itself a source of new troubles for Poland. Besides this, the pride of Poland's Roman Catholic prelates, who looked down on the Uniate hierarchy, forced the Uniate Church into the position of a "peasant religion" and contributed to making it the social nucleus of anti-Polish Ukrainian nationalism. Even in Sigismund's time, Austria, competing with Poland for influence in the eastern Balkans, began to seduce the Ukrainian element (represented in organized form by the military community of the Cossacks) against Poland—a policy which the same Austria was to resume later in changed form and under different conditions when in possession of eastern Galicia.

Swedish, Muscovite, and Turkish Wars.—The dispute over Sigismund's rights to the Swedish crown began, from the earliest years of the reign, to drag its weary course of alternate victories and defeats. Having obtained the Swedish crown (1592), Sigismund III met strong Protestant opposition, which defeated him in 1598, forcing him to abdicate. This eventually was the beginning of the wars between Poland and Sweden. At first the areas that later became Estonia and Latvia were both the scene and the principal object of the strife; in the later stages, Gustavus II Adolphus of Sweden transferred the ground nearer to the heart of Poland which helped the cause of the elector of Brandenburg, who had come into possession of Ducal Prussia and thus laid the foundation of a large Protestant power on the Baltic. The danger to Gdansk and Poland's grain exports roused even the gentry from their apathy; but in spite of some brilliant victories by sea and land, an armistice toward the end of the reign was highly unfavourable to Poland.

Sigismund's persistent Swedish ambitions, his equally persistent Austrian sympathies, but, more than all, his absolutist leanings and cherished plans for a drastic and arbitrary constitutional reform on foreign models and on antiparliamentary lines, occasioned in 1606 an armed revolt of the Polish gentry against their king—the *rokosz* ("insurrection") of Mikolaj Zebrzydowski,

who was supported by the discontented Protestants. The *rokosz* was at last suppressed in 1607, but it left as its legacy such ruinous precedents as an enforced recognition of the doctrine of the subjects' right to depose their king (*de non praestanda obedientia*) and, after being undertaken in justified defense of the native parliamentary tradition against wholesale foreign innovations, had the harmful effect of blocking the way toward any and every reform of the parliamentary system.

Soon after the constitutional cataclysm of the *rokosz*, Poland became embroiled in prolonged wars with Moscow. The motive was partly a vague conception of a Polish-Russian union as opposed to the king's Austrian propensities, but partly also the very real desire of some border magnates for more and more land east of the Dnieper. An occasion was furnished by the extinction of the dynasty of Rurik in Russia and the subsequent struggle for the throne, particularly the emergence of one candidate—the ill-fated false Dimitri (*see* DIMITRI, FALSE)—whom certain Polish nobles and finally also the king supported. The appearance of a second false Dimitri after the fall of the first served to prolong the strife.

Throughout the campaigns against Moscow the king found himself at variance with some leading Polish statesmen and soldiers of the time, such as Zamoyski and, later, Stanislaw Zolkiewski; Sigismund thought of the problem only in terms of conquest, of the establishment of Catholicism in Russia and of strong monarchical rule over the united kingdoms, while Zolkiewski, even at the height of military successes against Russia, had a union like that of Poland with Lithuania in his mind and advocated tolerance of Russia's creed and social order. The Poles once actually held the Kremlin of Moscow for a time (1610-11) and once again laid siege to it (1618); Sigismund's son Wladyslaw was elected tsar, and his opponent did homage to Sigismund as a prisoner. But a national insurrection in Russia and the establishment of the Romanov dynasty checked the Polish advance, and only certain territorial gains (including Smolensk), as well as a good deal of influence of Polish customs and institutions on the Russian nobility, were definite results of the struggle in Sigismund's time. It was to be continued under his successors.

The wars with Moscow temporarily ended in an armistice at the very moment (1618) when the Thirty Years' War broke out in central Europe. In this Poland remained officially neutral, but Sigismund's favourable attitude toward the Habsburgs (whom he sent unofficial reinforcements) entangled Poland in renewed and long wars with Turkey, which the later Jagiellons and their first successors had managed to avoid. A definite success was attained against the Turks at Khotin (Hotin), on the Dniester, in Besarabia (1621), a year after Zolkiewski's heroic death at Cecora (Tutora in Moldavia). But the Swedish trouble began anew in the same year, and Sigismund's long and unlucky reign ended 11 years later amid turmoil abroad and at home, setbacks to Polish power on all sides without, and seriously increased constitutional disorder within.

4. Wladyslaw IV, 1632-48.—Sigismund's son, born in Poland and brought up as a Pole, enjoyed a popularity which had never been his father's lot. As crown prince, he had been successful in military operations against Moscow and Turkey; on his ascension to the throne he ingratiated himself with the gentry; but essentially he collaborated with a group of nobles at his court. The "wisest of the Polish Vasas," as he has been called, intended to create a basis of public favour and confidence for the constitutional reforms which he planned.

But the international difficulties inherited from his father diverted his energies largely into channels of foreign policy. The very first years of his reign were marked by new victories over Russia near Smolensk (1634) and also by a new and much more advantageous truce with Sweden which, in 1635, withdrew from Royal (or Polish) Prussia. He was less fortunate in a new conflict with Gdansk, and with its supporter Denmark, over the tolls he intended to impose on the trade of the Baltic ports; no interest in these matters was to be awakened in the gentry, and the most powerful magnates—those of the eastern border—thought more of expansion into the fertile Ukrainian regions than of sea power.

Accordingly, the Polish Navy, which had begun to develop in a promising manner under Sigismund II, was allowed to fall into permanent decay, and Wladyslaw's plans for foreign action on a large scale were unrealized. He wavered in his diplomacy between Austrian and French influences, represented by his two successive queens; his tolerant and friendly attitude toward the Orthodox East caused serious trouble with the Vatican; and his project of a great crusade against the Turks, although encouraged by the Venetian republic and acclaimed by the South Slav nations, in the end came to nothing. He did not profit from the Thirty Years' War, obtaining only for several years the possession of a small part of Silesia (the duchy of Opole and Raciborz), whereas his predecessors had thought of regaining all Silesia.

The Cossack Revolt.—The chief obstacle which prevented Wladyslaw's Turkish plans from maturing was the impossibility of winning the help of the decisive factor, the Ukrainian Cossacks, who had become too numerous and powerful to be willing instruments of Polish policy. Catholic intolerance toward this Orthodox population, in the time of Sigismund III, had combined with the policies of Polish landowners to produce in the Cossacks a spirit of religious, racial, and social enmity against the Polish element; the Polish Parliament had not kept the financial terms of its compacts with the Cossacks; repressions inspired by the border magnates had infuriated them. Polish magnates, creating immense land estates, oppressed the peasants and town dwellers, enforcing on them high and unfair levies; and this prepared ground for revolutionary movements. Already in the earlier years of Wladyslaw's reign (as during that of Sigismund III) terrible Cossack revolts had flared up and been wisely punished by the abolition of ancient privileges. Now, instead of letting themselves be made the tools of Wladyslaw's anti-Turkish plans, the Cossacks made common cause with the Tatars of the Crimea, who were the most immediate objective of the king's crusading plans; and the reign ended amid a wave of Cossack insurrection, engineered by the sultan, assisted by Tatar hordes and led by Bohdan Chmielnicki (*q.v.*), a country gentleman personally wronged by a Polish official. It was only the resistance of the Polish burghers of Lwow that stemmed the Cossack and Tatar tide from flooding the inner provinces of Poland. But the defense of Lwow meant only a respite, and on Wladyslaw's death his brother and successor, the last of the Polish Vasas, found himself faced by a powerful renewal of Chmielnicki's attack on central Poland.

5. John Casimir, 1648-68.—John Casimir, summoned to the throne from Italy, where he had lived as a priest and become a cardinal, was obliged to begin his reign by negotiating with his rebel subject Chmielnicki. But Chmielnicki's conditions of peace were so hard that the negotiations came to nothing. It was only after a second invasion of Poland, in 1649, by a host of Cossacks and Tatars, that the Compact of Zborow was concluded, by which Chmielnicki was officially recognized as chief (hetman) of the Cossack community. A general amnesty was also granted, and it was agreed that all official dignities in the Orthodox palatinates of the Polish kingdom should henceforth be held solely by the Orthodox gentry. For the next 18 months Chmielnicki ruled the Ukraine like a sovereign prince. He made Czehryn (Chehryn), his native place, the Cossack capital, subdivided the country into 16 provinces and entered into direct relations with foreign powers. The Orthodox patriarchs of Alexandria and Constantinople were his friends and protectors, and Russia established relations with him. But fortune, so long Chmielnicki's friend, deserted him, and at Beresteczko (Berestechko; 1651) the hetman, betrayed by the Tatars who had helped him thus far, was utterly routed by John Casimir. All hope of an independent or even autonomous Cossackdom was at an end, yet it was not Poland but Moscow which reaped the fruits of successive victories and defeats.

Chmielnicki, by laying bare the nakedness of the Polish republic, had opened the eyes of Moscow to the fact that its ancient enemy was no longer formidable. Three years after his defeat at Beresteczko, Chmielnicki, unable to cope with the Poles single-handed, very reluctantly transferred his allegiance to the tsar Alexis Mikhailovich, whose armies, after the Pereyaslav agreement (1654), invaded Poland and began what is known in Russian

history as the Thirteen Years' War. The Russians occupied Wilno and a large part of Lithuania.

In the summer of 1655, while Poland was still reeling beneath the shock of the Muscovite invasion, Charles X Gustavus of Sweden, on the flimsiest of pretexts, launched a war to establish a Swedish mastery over the Baltic; and before the year was out his forces had occupied Warsaw, Cracow, and the best half of Poland. John Casimir, betrayed and abandoned by his own subjects (headed by the nobles of the country), fled to Silesia.

In this crisis Poland was saved, first, by an upsurge of patriotic and religious feeling among the peasants, townsmen, and gentry, and, second, by the formation of a league against Sweden with the participation of Austria and reinforcements from the Tatars. The people undertook guerrilla warfare; and the famous defense of the monastery of Czestochowa by its prior Augustyn Kordecki was followed by the king's return, by the organization of a new national army, and by the recovery of almost all the Polish provinces from the Swedes, who after a long fight were pushed back to the sea by Stefan Czarniecki (*q.v.*). As well as the alliance with the Holy Roman emperor Leopold I (1657), Poland secured a truce with Moscow, whose armies acted against the Swedes in Livonia. Neither the help of György Rákoczy II, prince of Transylvania, nor that of Frederick William, elector of Brandenburg, brought any relief to the Swedes.

On the sudden death of Charles X, Poland seized the opportunity of adjusting all its outstanding differences with Sweden. By the peace of Oliwa (Oliwa; 1660), made under French mediation, John Casimir ceded northern Livonia and renounced all claim to the Swedish crown. The worst setback was that Poland was obliged, by the Treaty of Welawa (Wehlau) in 1657, to renounce sovereignty over Ducal Prussia. The war with Moscow was then prosecuted with renewed energy and changing luck. In 1664 a peace congress was opened, and the prospects of Poland seemed most brilliant; but at the very moment when it needed all its armed strength to sustain its diplomacy, the rebellion of Prince Jerzy Lubomirski involved the country in a dangerous civil war, compelled it to reopen negotiations with the Muscovites and practically to accept the Muscovite terms. By the truce of Andruszow (Andrusovo; 1667) Poland received back from Moscow Vitebsk, Polotsk, and Polish Livonia, but ceded in perpetuity Smolensk, Starodub, and, in the Ukraine, the whole of the eastern bank of the Dnieper. The Cossacks of the Dnieper were henceforth to be divided between the dominion of the tsar and the king of Poland. Kiev, the religious metropolis of southwestern Russia, was to remain in the hands of Moscow for two years.

The "truce" of Andruszow proved to be one of the most permanent peaces in history, and Kiev, though pledged to Russia for only two years, was never again to be recovered. Henceforth the political impact of Russia toward Poland was steadily to increase, without any struggle at all, although influences of Polish culture and manners, exercised chiefly through the Academy of Kiev, still continued to permeate Russia down to the advent of Peter I the Great.

6. The "Liberum Veto" in the 17th Century.—Poland had, in fact, emerged from the cataclysm of 1648–67 a moribund state, though its not unskilful diplomacy had enabled it for a time to save appearances. Its territorial losses, though considerable, were, in the circumstances, not excessive, and it was still a power in the opinion of Europe. But a fatal change had come over the country during the age of the Vasas. The period synchronized with and was partly determined by the new European system of dynastic diplomatic competition and the unscrupulous employment of unlimited secret service funds. This system was based on the rivalry of the houses of Bourbon and Habsburg, and very soon nearly all the monarchs of the continent and their ministers were in the pay of one or other of the antagonists. Poland was no exception to the general rule. To do them justice, the *szlachta* at first not only were free from the taint of official corruption but endeavoured to fight against it. But they themselves unconsciously played into the hands of the enemies of their country by making the so-called *liberum veto* an integral part of the Polish Constitution. The *liberum veto* was based on the assumption of

the absolute political equality of every Polish gentleman, with the corollary that every measure introduced into the Polish *sejm* must be adopted unanimously. Consequently, if any single deputy believed that a measure already approved of by the rest of the house might be injurious to his constituency, he had the right to exclaim *Nie pozwalam*, "I disapprove," the measure in question falling at once to the ground. All efforts toward increasing the power of the central government were held to be aimed against traditional freedom and were opposed. Subsequently this vicious principle was extended still further. A deputy, by interposing his individual veto, could at any time dissolve the *sejm*, and all measures previously passed had to be resubmitted to the consideration of the following *sejm*. The *liberum veto* was used for the first time during the *sejm* of 1652. Before the end of the 17th century it was used so recklessly that all business was frequently brought to a standstill. It became the chief instrument of foreign ambassadors or native magnates for dissolving inconvenient sessions, as a deputy could always be bribed to exercise his veto.

7. Michael Wisniowiecki, 1669–74.—With the election of Michael Wisniowiecki in 1669 a new era began. A native Pole, he was freely elected by the unanimous vote of the gentry; but he was chiefly chosen for the merit of his father, a great border magnate who had victoriously kept down the Cossacks, and he proved to be a passive tool in the hands of the Habsburgs. In view of this the French party rallied round Jan Sobieski, a military commander of rising fame. The dissensions between the two camps cost Poland a new defeat at the hands of the united Turks and Cossacks. Sealed by a shameful Treaty of Buczacz (Buchach; 1672), by which all Polish Ukraine came under Turkish suzerainty, this defeat was only wiped out by a brilliant victory of Sobieski's at Khotin (1673), which also, after King Michael's early death, carried him to the throne against an Austrian candidate.

8. John III Sobieski, 1674–96.—Connected with France by marriage and by political sympathies, Sobieski (*see* JOHN III), although he had half a lifetime of constant wars against the Turks behind him, stood at first, in accordance with French policy, for peaceful relations with Turkey and directed his eyes toward the Baltic, attempting with French help to check the rising Hohenzollern power in that quarter. But his secret dealings with France turned his own subjects against him, while continuous Turkish invasions forced him into war, until an attack of great magnitude, aimed at the very heart of Europe, called forth that unprecedented outburst of Polish heroism—the gallant rescue of Vienna in 1683. That great act was the last noble reflex of the great crusading impulse of the Middle Ages; it was a unique service, rendered in the old chivalrous spirit by one nation to another in an age of Machiavellian diplomacy and growing national selfishness. It won Poland offers of friendship from all the great powers. But its positive gains for Poland proved little. The "perpetual peace" negotiated by Krzysztof Grzymultowski in Moscow in 1686, by which Kiev was recognized as a part of Russia, did not buy any active support in further campaigns against Turkey, nor did the delivered Austria assist Poland in its endeavour to reestablish the Rumanian outpost against the Turks. In internal affairs various cliques of the nobles, some attached to Austria and some to France, obstructed the restoration of the hereditary monarchy.

9. Augustus II, 1697–1733.—On the death of John III no fewer than 18 candidates for the vacant Polish throne presented themselves. The successful competitor was Frederick Augustus I, elector of Saxony, who cheerfully renounced Lutheranism for the coveted crown and won the day because he happened to arrive last of all, with fresh funds, when the agents of his rivals had spent all their money. He was crowned, as Augustus II (*q.v.*), in 1697, and his first act was to expel from the country his French rival, François Louis de Bourbon, prince de Conti, whose defeat was also partly caused by the growing Russian influence, which, from the accession of Peter I the Great, especially after 1700, became a permanent factor in Polish domestic politics.

Good fortune attended the opening years of the new reign. In 1699 the long Turkish War, which had been going on since 1683, was concluded by the Peace of Karlowitz (Karlovci), whereby Podolia, the Ukraine and the fortress of Kamieniec Podolski were

retroceded to Poland by the Ottoman Porte. But the permanent weakening of Turkey brought little good, for the power of Russia soon became a greater menace to Poland than Turkey had ever been.

Shortly after the Peace of Karlowitz, Augustus was persuaded by the plausible Livonian exile Johann Reinhold Patkul to form a nefarious league with Frederick IV of Denmark and Peter I of Russia, for the purpose of despoiling the youthful king of Sweden, Charles XII. This he did as elector of Saxony, but it was Poland which paid for the hazardous speculation of its newly elected king. Throughout the Northern War (*q.v.*), which wasted northern and central Europe for 20 years (1700–21), all the belligerents treated Poland as if it had no political existence. Swedes, Saxons, and Russians not only lived upon the country, but plundered it systematically. The *sejm* was the humble servant of the conqueror of the moment, and the leading magnates chose their own sides without the slightest regard for the interests of their country, the Lithuanians for the most part supporting Charles XII, while the Poles divided their allegiance between Augustus and Stanislaw Leszczynski (*see* STANISLAW I), whom Charles introduced and maintained upon the throne from 1704 to 1709. At the end of the war Poland was ruined materially as well as politically. Augustus offered Courland, Polish Prussia, and even part of Great Poland to Frederick William I of Prussia, provided that he were allowed a free hand in the disposal of the rest of his kingdom. When Prussia declined this tempting offer for fear of Russia, Augustus went a step further and actually suggested that "the four eagles" (*viz.*, the black ones of Austria, Prussia, and Russia and the white eagle of Poland proper) should divide the other Polish territories among them. He died, however, before he could give effect to this shameless design.

10. Augustus III, 1733–63.—On the death of Augustus II, Stanislaw Leszczynski, who had, in the meantime, become the father-in-law of Louis XV of France, attempted to regain his throne with the aid of a small French force under Louis de Bréhan, comte de Plélo. Some of the best men in Poland, including the Czartoryski family (*see* CZARTORYSKI), were in Leszczynski's favour, and he was elected king for the second time. But there were many malcontents, principally among the Lithuanians, who solicited the intervention of Russia in favour of Frederick Augustus II of Saxony, son of the late king. A Russian Army appeared before Warsaw and compelled a phantom *sejm* (it consisted of but 15 senators and 500 of the *szlachta*) to proclaim Augustus III. Stanislaw and his partisans were besieged by the Russians in Gdansk, and with its surrender their cause was lost. He retired to become duke of Lorraine and Bar, keeping the title of king of Poland but leaving Augustus III in possession of the kingdom. (*See* POLISH SUCCESSION, WAR OF THE.)

Augustus III left everything to his minister, Heinrich von Brühl (*q.v.*), and Brühl entrusted the government of Poland to the Czartoryskis, who had close relations of long standing with the court of Dresden. "The Family," as their opponents sarcastically called them, were to dominate Polish politics for the next half century, promoting their own interests but also trying to introduce constitutional reforms such as the abolition of the *liberum veto* and the formation of a standing army.

Unfortunately, the other great families of Poland were obstinately opposed to any reform or, as they called it, any "violation" of the existing Constitution. The Potockis (*see* POTOCKI), in particular, whose possessions in southern Poland and the Ukraine covered thousands of square miles, hated the Czartoryskis and successfully obstructed all their efforts. In the Saxon period, every *sejm* was dissolved by the hirelings of some great lord or of some foreign potentate.

After a period of cooperation with the Saxon court, the Czartoryskis broke with their old friend Brühl and turned to Russia. Their intermediary was their nephew Stanislaw August Poniatowski, whom they sent, as Saxon minister, to the Russian court in the suite of the English minister Sir Charles Hanbury Williams in 1755. The handsome and insinuating Poniatowski speedily won the heart of the grand duchess Catherine, but he won nothing else and returned to Poland in 1759 somewhat discredited. Never-

theless, the Czartoryskis looked to Russia again for support on Augustus III's death and rejected with derision the pacific overtures of their political opponents.

The reigns of Augustus II and Augustus III saw the economic, political, and cultural decline of Poland. The Polish economy, based on farming, serfdom, and grain export, was in serious difficulties because of decreasing opportunities on Western European markets. The situation was aggravated by the devastations of war and by a general agricultural crisis lasting from the middle of the 17th century to the middle of the 18th. The peasants and the towns were ruined; and the small gentry suffered likewise to a great extent, losing its estates to the magnates, whose wealth and political influence rose considerably. The Jesuit schools were chiefly concerned with spreading religious devotion, and the standard of general culture was much hampered by wars and by economic regression. The first symptoms of economic revival, together with attempts at reforming the school system, appeared toward the middle of the 18th century, announcing the coming of the Enlightenment.

11. Stanislaw II Poniatowski and the Partitions, 1764–95.

—The simplicity of the Czartoryskis was even more mischievous than their haughtiness. They took advantage of the *interregnum* to carry out a *coup d'état* restricting the *liberum veto*, creating ministerial commissions, and initiating other reforms. Their naïve expectations were very speedily disappointed. Catherine II and Frederick II had already determined (Treaty of St. Petersburg, 1764) that the existing state of things in Poland must be maintained, and as early as 1763 Catherine had recommended the election of Stanislaw August Poniatowski as "the individual most convenient for our common interests."

Shortly afterward Poniatowski was elected king with the help of Russian troops (*see* STANISLAW II), and crowned. But late in November 1763 Prince Nikolai V. Repnin (*q.v.*) was sent as Russian minister to Warsaw with instructions which led to further discord in Polish affairs. The first weapon employed was the question of the dissidents. At that time the population of Poland was, in round numbers, 11,420,000 of whom about 1,000,000 were dissidents or dissenters. Half of these were the Protestants of the towns of Polish Prussia and Great Poland, the other half was composed of the Orthodox population of Lithuania. The dissidents had no political rights, and their religious liberties had also been unjustly restricted. For these persons, mainly agricultural labourers, artisans, and petty tradesmen, Repnin, in the name of the empress, demanded absolute equality, political and religious, with the Catholic population of Poland. He was well aware that an aristocratic and Catholic assembly like the *sejm* would never concede so preposterous a demand.

Early in 1767 the malcontents, chiefly conservative magnates supported by Repnin, formed at Radom a confederation whose first act was to send a deputation to St. Petersburg, petitioning Catherine to guarantee the liberties of the republic. With a *carte blanche* in his pocket, Repnin proceeded to treat the *sejm* as if it were already the slave of the Russian empress. But despite threats, wholesale corruption, and the presence of Russian troops outside and even inside the Chamber of Deputies, the patriots, headed by four bishops, offered a determined resistance to Repnin's demands. Only when brute force in its extremest form had been ruthlessly employed, when two of the bishops and some other deputies had been arrested in full session by Russian grenadiers and sent as prisoners to Kaluga, did the opposition collapse. The delegation of the *sejm* accepted the so-called fundamental laws: the *liberum veto* and all the other ancient abuses were now declared unalterable parts of the Polish constitution, which was placed under the guarantee of Russia. All the restrictions against the dissidents were, at the same time, repealed.

Confederation of Bar.—This shameful surrender led to a Catholic patriotic uprising, known as the Confederation of Bar (*q.v.*), which was formed in 1768 at Bar in the Ukraine, by a handful of squires. It never had a chance of permanent success, though, feebly fed by French subsidies and French volunteers, it lingered on for four years, until finally suppressed in 1772. Insignificant in itself, the Confederation of Bar was the cause of great events.

Some of the Bar confederates, scattered by the Russian regulars, fled over the Turkish border, pursued by their victors. The Turks, already alarmed at the progress of the Russians in Poland and stimulated by Charles Gravier, comte de Vergennes, at that time French ambassador at Constantinople, at once declared war against Russia. Seriously disturbed at the prospect of Russian aggrandizement, the courts of Berlin and Vienna conceived the idea that the best mode of preserving the equilibrium of Europe was for all three powers to readjust their territories at the expense of Poland. Negotiations led to no definite result at first; then Austria took the first step by occupying, in 1769, the county of Spisz (Szepes, Zips), which had been hypothecated by Hungary to Poland in 1411 and never redeemed. This act decided the other powers; in June 1770 Frederick II of Prussia threw a military cordon, ostensibly to keep out the cattle plague, around those of the Polish provinces which he coveted. Catherine's consent had been previously obtained.

First Partition, 1772.—The first treaty of partition was signed at St. Petersburg between Prussia and Russia on Feb. 17, 1772; the second treaty, which admitted Austria also to a share of the spoil, was signed on Aug. 5 of the same year. The consent of the *sejm* to this act of brigandage was extorted by bribery and force in 1773. Russia obtained the palatinates (*województwa*) of Vitebsk, Polotsk, Mscislaw: 35,907 sq.mi. (92,999 sq.km.) of territory, with a population of 1,300,000. Austria got Little Poland without Cracow and also Lwow, Tarnopol (Ternopol), and Halicz (Galich) and, by extending the name of the last, called the new province Galicia: 31,622 sq.mi. (81,901 sq.km.), with a population of 2,650,000. Prussia received the palatinate of Pomorze minus Gdansk, the palatinate of Chelmno minus Torun, the northern half of Great Poland, and the palatinates of Malbork (Marienburg) and Warmia, calling the new acquisition West Prussia: 14,015 sq.mi. (36,299 sq.km.), with a population of 580,000. The total area of Poland before 1772 was about 283,204 sq.mi. (733,498 sq.km.), with an estimated population of 11,420,000.

The partitioning powers presented Poland with a new constitution. The elective monarchy and the *liberum veto* were of course retained. Poland was to be dependent on its despoilers, but they evidently meant to make it a serviceable dependent. The government was henceforth to be in the hands of a permanent council of 36 members, 18 senators, and 18 deputies, elected biennially by the *sejm* in secret ballot, subdivided into the five departments of Foreign Affairs, Police, War, Justice, and the Exchequer, whose principal members and assistants, as well as all other public functionaries, were to have fixed salaries. The royal prerogative was still further reduced. The king was indeed the president of the Permanent Council, but he could not summon the *sejm* without its consent and in all cases of preferment was bound to select one out of three of the Council's nominees. Still, the new organization made for order and economy and enabled Poland to develop and husband its resources and devote itself uninterruptedly to the now burning question of national education.

The shock of the first partition had a certain salutary effect on national mentality. Already in the darkest days of Saxon rule, important educational reforms had been carried out in the schools of the Piarist order by Stanislaw Konarski (q.v.). Now, the dissolution of the Society of Jesus in 1773, putting its rich possessions and the system of schools conducted by it into the hands of the state, gave Poland opportunity to secularize as well as to modernize the whole educational fabric of the nation. This huge task was admirably performed by the Commission of National Education, the first Ministry of Education in Europe. It reorganized both the program of teaching and the structure of the schools—including the decayed universities of Cracow and Wilno—in a thoroughly modern and enlightened way. Less progress was made with the cause of constitutional reform: the chancellor Andrzej Zamoyski indeed drafted a new comprehensive code of laws, in which a beginning was made with the emancipation of the peasant serfs and of the town population, but this was rejected by the gentry in the *sejm* (1780).

In the meantime, events in the international field seemed to give Poland another chance of reasserting its independence against its despoilers. The death of Frederick II in 1786 loosened the bonds

of the alliance between Prussia and Russia. Russia, drawing nearer to Austria, undertook, jointly with Austria, a war against Turkey which proved unexpectedly hard; and Russia was at the same time attacked by Sweden. Prussia, having changed its policy and concluded an alliance against Russia with Great Britain and Holland, was now emboldened by Russia's difficulties to go further: it invited Poland also to forsake the Russian alliance and offered to place an army corps of 40,000 men at its disposal.

The Constitution of May 3, 1791.—It was under these exceptional circumstances that the "four years' *sejm*" assembled (1788). Its leaders, Stanislaw Malachowski, Hugo Kollataj (q.v.) and Ignacy Potocki, were men of character and capacity, and its measures were correspondingly vigorous. Within a few months of its assembling it had abolished the Permanent Council, enlarged the royal prerogative, raised the army to 65,000 men, established direct communications with the Western Powers, declared its own session permanent, and finally settled down to the crucial task of reforming the constitution on modern lines. But the difficulties of the patriots were commensurate with their energies, and it was not till May 1791 that the new constitution could safely be presented to the *sejm*. Meanwhile, Poland endeavoured to strengthen its position by an alliance with Prussia. Frederick William II stipulated at first that Poland should surrender Gdansk and Torun; but the Poles proving obstinate and Austria simultaneously displaying a disquieting interest in Poland's welfare, Prussia on March 19, 1791, concluded an alliance with Poland which engaged the two powers to guarantee each other's possessions and render mutual assistance in case either were attacked.

But external aid was useless so long as Poland was hampered by its anarchical constitution. The most indispensable reforms had been frantically opposed; the debate on the reorganization of the army alone had lasted six months. It was only by an audacious surprise that Kollataj and his associates contrived to carry through the new constitution. Taking advantage of the Easter recess, when most of the malcontents were out of town, they suddenly, on May 3, brought the whole question before the *sejm* and demanded urgency for it. Before the opposition could remonstrate, the marshal of the *sejm* produced the latest foreign dispatches, which unanimously predicted another partition, whereupon, at the solemn adjuration of Ignacy Potocki, King Stanislaw exhorted the deputies to accept the new constitution as the last means of saving their country; and he set the example by swearing to defend it.

The constitution of May 3, 1791, converted Poland into a hereditary limited monarchy, with ministerial responsibility and biennial parliaments. The *liberum veto* and all the intricate and obstructive machinery of the anomalous old system were forever abolished. All invidious class distinctions were done away with. The towns, in a special bill confirmed by the new constitution, got full administrative and judicial autonomy; as well as a certain measure of parliamentary representation; the personal privileges of the gentry, such as possession of land and access to office in the state and in the church, were thrown open to the townsmen. The peasants were placed under the protection of the law, and their serfdom was mitigated. Absolute religious toleration was established. Provision was made for further periodical reforms by subsequent Parliaments.

The Confederation of Targowica.—The constitution of May 3 had scarcely been signed when Stanislaw Feliks Potocki, Seweryn Rzewuski, and Ksawery Branicki, three of the chief dignitaries of Poland, hastened to St. Petersburg and there entered into a secret convention with the empress, whereby she undertook to restore the old constitution by force of arms but at the same time promised to respect the territorial integrity of the republic. Entering Polish territory with Russian troops, the conspirators on May 14, 1792, proclaimed a confederation at the little town of Targowica in the Ukraine, protesting against the new constitution as tyrannous and revolutionary; four days later, the new Russian minister in Warsaw presented a formal declaration of war to the king and the *sejm*.

The *sejm* met the crisis with dignity and firmness. The army was at once dispatched eastward to meet the invading Russians;

the male population was called to arms, and Ignacy Potocki was sent to Berlin to claim the assistance stipulated by the treaty of 1791. The king of Prussia, in direct violation of all his oaths and promises, declined to defend a constitution which had never had his "concurrence." Thus Poland was left entirely to its own resources. The little Polish Army of 46,000 men, under Prince Jozef Antoni Poniatowski, nephew of King Stanislaw II, and Tadeusz Kosciuszko (*q.v.*), did all that was possible under the circumstances. For more than three months they kept back the invader, and, after winning three pitched battles, retired in perfect order on the capital (*see* PONIATOWSKI). But the king, and even Kollataj, despairing of success, now acceded to the confederation; hostilities were suspended; the indignant officers threw up their commissions; the rank and file were distributed all over the country; the reformers fled abroad; and the constitution of May 3 was abolished by the Targowicians as a "dangerous novelty." As the Russians occupied all eastern Poland, the Prussians, at the beginning of 1793, alarmed lest Catherine should appropriate the whole republic, seized Great Poland; and a diminutive, debased, and helpless *sejm* met at Grodno in order, in the midst of a Russian Army Corps, "to come to an amicable understanding" with the partitioning powers.

Second Partition, 1793.—After every conceivable means of intimidation had been unscrupulously applied, the second treaty of partition was signed at three o'clock on the morning of Sept. 23, 1793. By this *pactum subjectionis*, as the Polish patriots called it, Russia got all the eastern provinces of Poland, extending from Livonia to Moldavia, comprising a territory of 96,602 sq.mi. (250,199 sq.km.), while Prussia got Dobrzyn, Kujavia, Great Poland, Torun, and Gdansk (22,046 sq.mi. [57,099 sq.km.]). Poland was now reduced to 83,012 sq.mi. (215,001 sq.km.), less than one-third of its original dimensions, with a population of about 4,000,000.

Kosciuszko and the Third Partition.—The focus of Polish nationalism was now transferred from Warsaw, where the Targowicians and their Russian patrons reigned supreme, to Leipzig, where the Polish patriots, Kosciuszko, Kollataj, and Ignacy Potocki among the number, assembled from all quarters. From the first they meditated a national rising, but their ignorance, enthusiasm, and simplicity led them to commit blunder after blunder. The first of such blunders was Kosciuszko's mission to revolutionary France in January 1793. He was full of the idea of a league of republics against the league of sovereigns; but he was unaware that the Jacobins themselves were already considering the best mode of detaching Prussia, Poland's worst enemy, from the anti-French coalition. Kosciuszko received an evasive reply and returned to Leipzig empty-handed. In the meantime, certain officers in Poland had revolted against the reduction of the Polish Army to 15,000, imposed upon the country by the partition treaty. Kosciuszko himself condemned their hastiness; but the march of events forced his hand, and on March 23, 1794, he went to Cracow, proclaimed a national insurrection and assumed the powers of a dictator. He called the peasants to arms, and they responded nobly, in return for which he supplemented the provisions of the constitution of 1791 by a manifesto giving them personal freedom and limited obligation toward the gentry. At first, Kosciuszko's arms were almost universally successful. The Russians were defeated in pitched battles, three-quarters of the ancient territory was recovered, and Warsaw and Wilno were liberated by popular uprisings.

The first serious reverse at Szczekociny was outweighed by the defense of Warsaw against the Russians and Prussians (July 9–Sept. 6). But even during that heroic defense the mood of the Warsaw mob became more radical, and violent dissensions in the Supreme Council and in the army, notwithstanding the extension of the rising to Great Poland, began to complicate the dictator's task. The appearance of overwhelming masses of Russian troops, together with the open hostility of Austria as well as Prussia, did the rest, and Kosciuszko's insurrection received its deathblow on the battlefield of Maciejowice, where he himself was wounded and taken prisoner. Warsaw was taken amid a terrible massacre in the suburbs of Praga, and the remainder of the troops capitulated a few weeks later.

TERRITORIAL CHANGES IN POLAND DURING THE 18TH CENTURY

The greed of the victorious powers nearly led to a rupture between Austria and Prussia, but, after some dissension, the third partition of Poland was effected by treaties in 1795 and 1796. Austria had to be content with Lublin, Siedlce, Radom, and Kielce (18,147 sq.mi. [47,001 sq.km.]), while Prussia took Suwalki, Bialystok, Lomza, and Warsaw (18,533 sq.mi. [48,000 sq.km.]). Russia annexed all the rest (46,332 sq.mi. [120,000 sq.km.]) and was afterward to tear even parts of their booty from the two others. Thus the name of Poland was wiped from the map of Europe.

The estimated population of Poland in 1795 (in 1772 frontiers) was 13,500,000; of that number Prussia subjected 3,105,000 (23%), Austria 4,320,000 (32%), and Russia 6,075,000 (45%). Of the territory of Poland in 1772 Prussia annexed 19.5%, Austria 17.5%, and Russia 63%. Almost all lands ethnically Polish fell under Prussian or Austrian domination.

The destruction of the Polish state supervened on a period of regeneration and of political, economic, and cultural revival. The reign of Stanislaw II Poniatowski, so lively in the political and social field, had seen a growth of the rural economy, as the peasant's condition became better, and the towns—especially Warsaw—had prospered. Grain exports had increased, despite Prussian restrictions; industrial plants had appeared in various parts of the country; and in the towns trading and banking had risen. In the field of general culture the results of education and wealth were apparent.

The partitions of Poland forced the separated parts of the nation to live under three different political, constitutional, and economic regimes. The gentry, and especially the magnates, having lost their former political role, tried to adjust themselves to life under the new conditions, but the towns and economic life as a whole fell into a decline, except in Austrian Poland, where the reforms introduced by Joseph II protected the peasants from abusive exploitation by the landowners.

(R. N. B.; R. Dy.; A. Wv.)

D. THE DUCHY AND FOREIGN RULE

After the third partition, the more high-spirited Poles, chiefly officers and soldiers of Kosciuszko's army, emigrated and formed, on Italian soil, the Polish Legions, hoping to return to Poland with the revolutionary French Army. During the next ten years they fought the battles of the French republic and of Napoleon all over Europe and even outside it, from Egypt to the West Indies. They were commanded by Jan Henryk Dombrowski (*q.v.*),

one of Kosciuszko's ablest generals; but Kosciuszko himself stood aloof, distrusting Napoleon.

1. The Duchy of Warsaw.—In 1806 and 1807, when Napoleon defeated Prussia and engaged in a war with Russia, Polish soldiers once more appeared on Polish soil, and the hopes of the nation seemed near fulfillment. In fact, the Peace of Tilsit resulted in the reconstruction of a Polish state out of the central provinces of Prussian Poland; but Napoleon's anxiety to conciliate Russia effectually prevented him from making his new creation large enough to be self-supporting. The Duchy of Warsaw, as it was called, consisted in 1807 of territories taken by Prussia in the second and third partitions, with three exceptions: Gdansk (Danzig) became a free city; the district of Bialystok was given to Russia; the so-called Netec (Netze) district, annexed by Prussia in the first partition, was added to the duchy. In 1809 the duchy was increased by the territory which Austria had seized in the third partition. The total area of the duchy was then about 59,382 sq.mi. (153,799 sq.km.), with a population of 4,350,000.

The constitution of July 22, 1807, was dictated by Napoleon; it was framed on the French model and on very advanced lines. Equality before the law (implying personal freedom of the peasant), absolute religious toleration, and highly developed bureaucracy were its salient features. The king of Saxony, Frederick Augustus I (previously elector as Frederick Augustus III; grandson of Augustus III of Poland), whom Napoleon made duke, took the initiative in all legislative matters, but the administration was practically controlled by the French. In spite of being subject to most burdensome financial and military exigencies for the purposes of Napoleon's continuous wars, the duchy contrived, during the few years of its existence, to do much productive, organizing work. The country's economic position worsened because production was geared for military purposes, but the middle class profited from its new legal and social status.

Poland's hopes for greater things revived once more when Napoleon announced his war against Russia (1812), as his "second Polish war." The duchy, by an immense effort, put an army corps of nearly 98,000 men into the field. But the calamity that overtook Napoleon in Russia also sealed the fortunes of the duchy. The remainder of the Polish troops faithfully followed Napoleon in his campaign of 1813-14, during which the heroic leader of the Poles, Prince Jozef Antoni Poniatowski, perished in covering the

emperor's retreat from Leipzig. The duchy was occupied by the Russians.

2. The Congress Kingdom and Russian Rule.—The Russian emperor Alexander I had been united by youthful friendship to the most eminent Polish noble of his time, Prince Adam Jerzy Czartoryski, and had even made him, on his accession, foreign minister of the Russian empire. On Napoleon's downfall the Poles, to whom Alexander did not spare promises and flatteries, entertained the highest hopes.

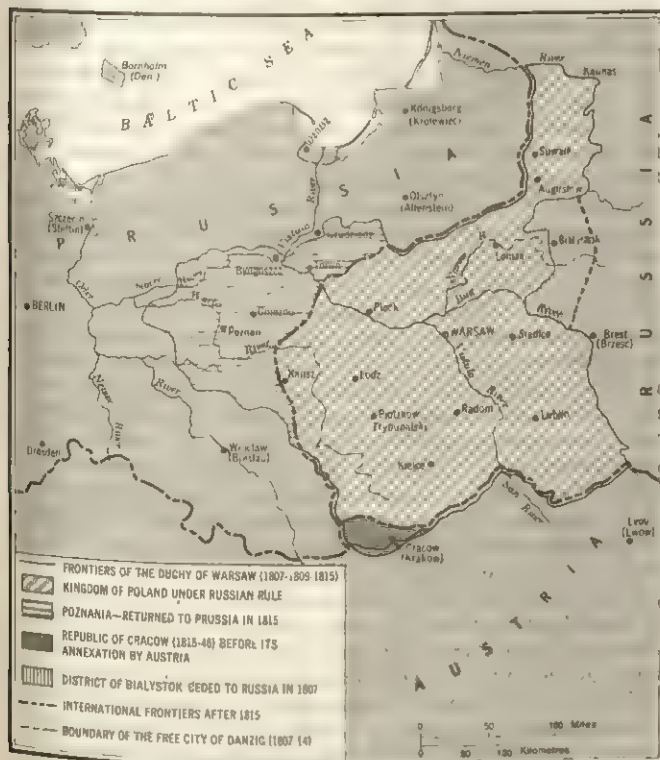

It was not Alexander's fault, indeed, if the Congress of Vienna, because of jealousy among the great powers and the entanglement of the Polish question with that of Saxony and other territories, did not lead to a reunification of Poland, even under the Russian sceptre, but confirmed the division of the country among the three partitioning powers. Only Cracow, with a small surrounding territory (449.2 sq.mi. [1,163 sq.km.], with a population of 95,000), was erected into a free republic. Great Poland, with Poznan for its centre, was left to Prussia. Austria remained in possession of a slightly reduced Galicia (30,212 sq.mi. [78,249 sq.km.], with 3,500,000 inhabitants). The eastern borderlands, from Lithuania and Belorussia to the Ukraine, continued to be incorporated in Russia. The remnant of central Poland only (49,217 sq.mi. [127,472 sq.km.], with a population of 3,300,000) was constituted as the so-called Congress Kingdom under the emperor of Russia as king of Poland. Guarantees of home rule in all parts of the divided country and of free communication between them were given by all powers concerned, only to prove soon more or less futile.

Alexander, who had a sentimental regard for freedom, so long as it meant obedience to himself, had promised the Poles a constitution. That constitution was soon duly drafted and signed. It provided that the Kingdom of Poland was to be united to Russia in the person of the emperor, as a separate political entity. Lithuania and the Ruthenian palatinates continued to be incorporated with Russia as the Western Provinces and were divided from the Congress Kingdom by a customs barrier till the reign of Nicholas I. The Poland thus defined was to have at its head a lieutenant of the emperor (*namiestnik*), who must be a member of the imperial house or a Pole. The first holder of the office, Gen. Jozef Zajaczek (1752-1826), formerly a political radical but now a conservative, was a veteran who had served Napoleon.

Roman Catholicism was recognized as the religion of the state, but other religions were tolerated. Liberty of the press was promised, subject to the passing of a law to restrain its abuses. Individual liberty, the use of the Polish language in the law courts, and the executive employment of Poles in the civil government were secured by the constitution. The machinery of government included a council of state (at which the imperial government was represented by a commissioner plenipotentiary) and a *sejm* divided into a Senate, composed of the princes of the blood, the palatines and councillors named for life, and a House of Deputies elected for seven years. Poland retained its flag and a national army based on that which had been raised by and had fought for Napoleon. The command of the army was given to the emperor's brother Constantine (*q.v.*), a man of somewhat erratic character, who did much to offend the Poles by violence.

The *sejm* met three times during the reign of Alexander, in 1818, in 1820, and in 1825, and was on all three occasions opened by the emperor. But Alexander and the *sejm* soon quarreled. The third session of the *sejm* (May 13 to June 13, 1825) was a mere formality. All publicity was suppressed, and one whole district was disfranchised because it persisted in electing candidates who were disapproved of at court. All Europe at the time was seething with secret societies organized to combat the reactionary governments of the Holy Alliance. In Poland the National Freemasonry, or National Patriotic Society as it was afterward called, had a large membership, especially among the students and the younger officers. Outside Congress Poland, a similar student movement arose in the University of Wilno. Severe measures—imprisonment, deportation, and exile—were taken against students and graduates of Wilno (including the poet Adam Mickiewicz), and they added to the excitement in Warsaw.

No open breach occurred during the reign of Alexander I, nor

THE DUCHY OF WARSAW AND THE POLISH KINGDOM

for five years after his death in 1825. On the death of the unpopular Zajaczek in 1826, the grand duke Constantine became imperial lieutenant. His brother, the new emperor Nicholas I, soon became entangled in a war with Turkey. Austria, as usual, desirous of profiting by Russia's difficulties, began to court the favour of the Poles. Nicholas was crowned king of Poland in Warsaw in 1829 and personally opened the *sejm* in 1830. But the *sejm* already in 1828 had refused to sentence to death a group of Polish conspirators accused of dealings with the Russian Dekabrists who had plotted Nicholas' overthrow, and in 1829 there was even an abortive Polish plot to murder him at his coronation in Warsaw. Fresh excitement was created in Poland by the outbreak of the Revolution in France in July 1830 and the revolt of Belgium; a rumour was current—not without justification—that Nicholas, acting in concert with the other autocrats of the Holy Alliance, intended to use the Polish Army to coerce the French and Belgian revolutionaries.

During the period of the Congress Kingdom, economic life and education were developing rapidly. The government aimed at strengthening the economy by a system of protection and state investment. The Land Credit Society (1825) and the Bank of Poland (1828) created by Ksawery Drucki-Lubecki, minister of the treasury, secured credits for municipal investments and for the development of communications. Mining, metallurgy (in the Kielce district), and the textile industry (Lodz, Zyrardow) were growing, while in agriculture the big farms were intensifying their production at the cost of the peasants' lands. In Warsaw a university (1816) and a college of engineering (1830) were founded to train specialists, while in the Russian provinces the Polish University of Wilno flourished.

The Rising of 1830.—On Nov. 29, 1830, a military insurrection broke out in Warsaw. It was started by the young hotheads of the officers' training school. Regiments of the army and masses of the civilian population began to join the rising; the weakness of Constantine allowed it to gather strength. He evacuated Warsaw and finally left the country. The war lasted from January to September 1831. The Poles began with some chances of success; they had a well-drilled and well-equipped army of about 30,000 men, which they increased by recruiting to about 80,000. Against this, the Russians, with considerable difficulty, succeeded in putting only about 114,000 men into the field. Their ultimate success resulted partly from the friendly attitude of Prussia, partly from the fact that the Polish *sejm*, having proclaimed the deposition of the Russian king at an early stage of the conflict, received no response to its appeal for Western European protection. But to a large extent the defeat of the insurrection was caused by certain faults on the Polish side: want of ability and decision on the part of the generals; a succession of rapid changes in the command of the army; fierce party strife within the civil government in the capital; a naïve hope for an agreement with the emperor instead of a vigorous military action, as recommended by a section of the insurrectionary government; and, finally, an irresolute attitude of the insurrectionary parliament toward the peasant claims.

The failure of the insurrection was followed by the exile of about 10,000 political leaders and soldiers—the "Great Emigration," which was concentrated mainly in France but was also represented in England, Belgium, and Switzerland. Soon the Emigration became divided into different political groups, of which the right wing, led by Prince Adam Czartoryski, undertook energetic diplomatic action aimed at interesting the Western powers in the Polish question. The left wing of the exiles established ties with the international revolutionary movements, seeking to prepare a new insurrection in Poland and hoping to win the peasants' support. With the Great Emigration, moreover, was associated the creative work of the most prominent Romantic poets.

After the suppression of the insurrection, certain remnants of a constitution were still granted to Russian Poland by the "Organic Statute" of 1832, but they were soon rendered illusory; the administration avowedly aimed at destroying the nationality and even the language of Poland. The universities of Warsaw and Wilno were suppressed; the Polish students were compelled to go to St. Petersburg and Kiev. After the disbanding of the Polish

Army, recruits from Poland were distributed in Russian regiments, and the use of the Russian language was enforced as far as possible in the civil administration and in the law courts. The customs barrier between Lithuania and the former Congress Poland was removed, in the hope that Russian influence would spread more easily over Poland. A hostile policy was adopted against the Roman Catholic Church. But though these measures cowed the Poles, they failed to achieve their main purpose. Polish national sentiment was intensified. The Poles in Russia, whether at the universities or in the public service, formed an element which refused to assimilate with the Russians. In Poland itself much of the current civil administration was left in the hands of the nobles, whose power over their peasants was hardly diminished and was misused as of old. The Polish exiles who filled Europe after 1830 maintained a constant agitation from abroad. The stern government of Nicholas I was, however, so far effective that Poland remained quiescent during the Crimean War, though the country was seething with plots and secret preparations for an insurrection.

Alexander II and the Rising of 1863.—The reign of the new emperor Alexander II began with certain concessions to Poland in the political and educational field. Exiles were allowed to return, administrative pressure was lightened, the church was propitiated, an Agricultural Society was allowed to be formed and to discuss important affairs of the community, a medical faculty and, later on, a complete university were reestablished in Warsaw. Finally, even a Polish council of state and a Polish administrative apparatus for the kingdom began to be organized. In their later stages these reforms were the work of Count Aleksander Wielopolski, who was installed in high office and stood for a national policy of loyal union with Russia. But his autocratic temper lost him the sympathies of the moderate elements of the gentry, while on the ardent minds of the young his methods acted like fuel heaped on fire. Religious ceremonies were used as the occasion for demonstrative political processions, there were collisions with the Russian troops, and victims fell in the streets of Warsaw. Wielopolski had the unhappy idea of causing the revolutionary youth of the cities to be recruited *en masse* for the Russian Army; the plan became known, numbers of the young people fled into the forests, and a revolutionary committee on Jan. 22, 1863, started an insurrection.

The struggle of the ill-equipped and ill-organized insurgent bands against the Russian garrisons dragged on in the form of guerrilla warfare throughout the country for nearly two years. A secret national government was set up in Warsaw, the movement spread successfully into Lithuania and the insurrection occupied the diplomatic attention of Western Europe. But the assistance promised by the French emperor Napoleon III never became effective; the rising was crushed; wholesale executions, confiscations, and deportations followed its suppression; and Poland was now definitely turned into a Russian province.

Russification.—All self-government in Congress Poland was suppressed in 1863; all education was russified in 1869, justice in 1873. On the other hand, the abolition in 1851 of the customs frontier between Russia and Poland had laid the foundation for an extraordinary industrial expansion: Russian Poland, with its great textile factories at Lodz, with the coal and iron-foundry centre at Dabrowa Gornicza, became the chief industrial region for all Russia. Its vast market in agricultural Russia was protected against Western competition by high tariffs; the Russian government took every possible measure (such as the introduction of specially favourable railway tariffs) to assist this expansion. The Poles, being excluded from state service in their own country, busied themselves with productive occupations, and the upper and middle classes achieved a well-being far superior to anything enjoyed by their cousins in Galicia. A second result of this expansion was the growth in Congress Poland of a large and radical proletariat which made common cause with the Russian Social Democratic movement. In the country districts, the agrarian policy of the Russian government was expressly calculated to stir up ill-feeling between the Polish peasants, whom the government demonstratively took under its protection, and the country gentry, whom it was determined to punish in every way for their leading part in the insurrections. In March 1864 the Russian government

promulgated an agrarian reform in Russian Poland by which all peasants, whatever their tenure had been, and the mass of the landless proletariat became freeholders, on a far more generous basis than the Russian peasants in 1861. The landlords received compensation in Russian treasury bonds, which stood far below par, and the peasants got the right to use the landlords' pastures and woods.

In the sphere of education, the most thoroughgoing system of russification set in after 1864. All the revived Polish schools of the Wielopolski period were made Russian again, including the University of Warsaw, and no effort was spared to produce in the minds of youth a distorted image of Poland's past. Secret patriotic education, however, counteracted this policy both in town and country, and private Polish schools, struggling against great difficulties, kept the Polish cultural tradition alive.

The civil government of Russian Poland was reorganized strictly on the model of the rest of the Russian empire, the Poles being debarred, however, from certain liberal institutions which the Russians by that time possessed, such as municipal self-government and trial by jury. The Russian language was made compulsory in all official relations and at a later time even in the records of private institutions. A corrupt Russian bureaucracy filled all government offices, censorship strangled every free utterance of the nation in the press and in literature, and a police regime kept the prisons filled with political offenders.

After Russia's defeat in the Japanese War of 1904, the outbreak of a revolution in 1905, which also engulfed the territory of the Congress Kingdom, kindled Polish hopes once more. A constitution was granted to the Russians, and 36 Polish deputies sat in the first Russian Duma. A certain measure of freedom in the educational field was obtained and eagerly used for the foundation of new schools by a Warsaw society called the Mother of Schools (*Macierz Szkolna*). The peasants of Russian Poland spontaneously introduced the Polish language in their self-governing bodies. In the Duma itself, the Liberals were not averse to granting Poland a large measure of autonomy within Russia. At the same time, persecution in Prussian Poland increased under Prince Bernhard von Bülow, while the Ukrainian national movement, developing in Austrian Poland especially since the grant of universal suffrage in 1907, was unwelcome both to Poles and Russians. Under these circumstances, Russian propaganda, reviving the pan-Slav ideals of 30 years ago, could count on some success even among the Poles. There were gestures of reconciliation at two Slav congresses, in 1908 and 1910, the Czechs willingly acting as mediators. The idea of uniting all Poles, with autonomy, within the Russian empire was widely preached; it became the program of the National Democratic, or all-Polish, Party, led by Roman Dmowski (*q.v.*), the head of the Polish representation in the second and third Dumas.

Opposed to Dmowski and the followers whom he found even among Austrian Poles there stood the irreconcilable revolutionaries, led by Jozef Pilsudski (*q.v.*). Both the insurrectionary movement started by Pilsudski in 1905 and the constitutional endeavour of Dmowski and his friends in the Duma were soon stifled by the Russian reaction. Pilsudski took refuge in Galicia and began to organize armed resistance to Russia from that base. In the Duma, the Polish representation was lowered from 36 to 10 deputies. In the country, all the liberties gained after 1905 soon disappeared. The government's purchase of the railway line from Warsaw to the Austrian frontier resulted in the removal of all Polish railwaymen from the service and was a great blow to the Polish element. In 1912 the separation of the district of Chełm, in the southeast of Russian Poland, from the body of the province and its incorporation in Russia proper was received with indignant protests by Polish opinion as a new partition of Poland.

3. Prussian Poland.—The regime in Prussian Poland during the first 15 years after the Congress of Vienna had been endurable. A Polish nobleman related by marriage to the Prussian dynasty—Prince Antoni Radziwill—was appointed lieutenant governor of the Poznan province; and there were a provincial assembly and local representative bodies both urban and rural. The landowners were allowed to organize for economic purposes, and the peasants were fully enfranchised in 1823. After the insurrection of 1830, a

period of more oppressive government by a German provincial *Oberpräsident*, Eduard Heinrich von Flottwell, set in; he revived Frederick II's method of German colonization of the Polish province, and he began to germanize the administration and the school system. A period of new concessions to the Poles under Frederick William IV was interrupted by the revolution of 1846–48. The constitution with which Prussia emerged from the revolution put an end to the self-government of Prussian Poland. Another interval of relaxation, in the first years of William I, was soon succeeded by the period of Bismarck's and Bülow's resolutely anti-Polish policy—characterized by the *Kulturkampf*, the Commission on Colonization, the Wrzesnia scandal, the schools' strike, the Law of Expropriation and the like, for an account of which see POZNAN. The result of the Prussian methods was to create a sturdy class of peasants and a *bourgeoisie*, economically and culturally advanced; and a fellow feeling arose between the peasants and the landowning gentry hardly known in other parts of Poland.

4. Austrian Poland.—After the insurrection of 1830–31, no remnant of Poland's independent political existence had been left except the minute republic of Cracow, created by the Congress of Vienna. For 30 years this miniature state led a flourishing existence. When the ferment of the approaching European revolution of 1848 was stirring most continental countries to their depths, there were active preparations for another rising both in Austrian and in Prussian Poland. For Austria the menace was diverted by a peasant revolt in Galicia in February 1846, which led to a massacre of about 2,000 landowners by the peasantry incited by the Austrian governor-general Baron Krieg von Hochfelden. At the same time, Austria availed itself of the unrest among its Poles to obtain the consent of Russia and Prussia to the suppression of the republic of Cracow. After a short-lived insurrection, Cracow was finally occupied by Austrian troops in March 1846 and incorporated into Galicia.

Austria under the old autocratic regime oppressed its Polish province politically and exploited it economically in the most ruthless fashion. The revolution of 1848 brought a change, but not until the defeat of Austria by Prussia in 1866 was it realized at Vienna that only a more liberal policy could hold the tottering, mixed monarchy together. The relation with Hungary having been placed on a federal footing, concessions had to be granted to the strong Polish element in Austria. The Poles began to be active in Austrian politics. The numerical strength of Polish deputies in the Vienna Parliament was such that no Austrian government could be formed without it. Galicia (as Austrian Poland was officially called), containing a large Ukrainian element in its eastern half, was granted a special minister to represent its interests in the Vienna cabinet. It also got a provincial legislative assembly and a governor, who was invariably appointed from the ranks of the Polish aristocracy. With purely Polish administration, schools, and courts of law, Galicia became indeed almost an independent Polish state within Austria and successfully defied the centralizing efforts of the Vienna bureaucracy.

The Polish landowning class, which practically governed the country for the next few decades, managed its affairs in a one-sidedly agrarian spirit; the interests of the towns were not properly considered, hardly any attention was given to the development of industries, and Galicia remained economically backward. Even its oil fields were largely developed by foreign capital. On the other hand, political and cultural activities had more scope than in the two other parts of Poland; Galicia became the "Piedmont" of the Polish national movement, and Cracow, with its old university and new Academy of Sciences, an intellectual, artistic, and literary centre for the whole nation. With the growth of a new educated class and the introduction of universal suffrage in Austria (1907) the social structure of the country began to change, its politics were strongly democratized, new economic tendencies got the upper hand, and Galicia was at last on the road to material advance when World War I began. (R. Dy.; A. Wy.)

E. THE POLISH QUESTION DURING WORLD WAR I

The Polish political groupings did not react to the outbreak of World War I in uniform manner. In all three parts of Poland

the Conservatives were loyal to the partitioning powers; the moderate Socialists and Peasant parties supported Germany and Austria-Hungary; the National Democrats rather sympathized with Russia, though they were engaged on Russia's side officially only in Russian Poland; and the left-wing Socialists took an anti-war position. A Supreme National Committee, striving for the unification of the Austrian and Russian parts of Poland in the Habsburg monarchy, came into being in Galicia on Aug. 16, 1914. Volunteer Polish Legions were set up at the side of the Austro-Hungarian Army under the supreme command of Austrian officers. Pilsudski became the commander of a brigade in these legions. In Congress (i.e., Russian) Poland, in November 1914, the Polish National Committee was established under the leadership of Dmowski: it called for support of Russia for the sake of unification of Poland under the sceptre of the emperor and in the name of common Slav interests. In a proclamation on Aug. 14, 1914, the Russian commander in chief, the grand duke Nikolai Nikolaevich, promised unification of Poland and autonomy within the Russian empire after a victorious war. The Central Powers exhorted the Poles to fight for freedom against Russia.

In the first year of World War I the front passed through the Russian and Austrian parts of Poland; in the summer of 1915 Congress Poland and nearly all of Austrian Poland were in the hands of the Central Powers. The military operations had caused great damage to Polish industry, agriculture, communications, and housing. About 800,000 persons had been evacuated into Russia. In the first year of the war more than 1,000,000 Poles were mobilized in the armies of the partitioning powers, and by the end of the war more than 2,000,000 were mobilized. The behaviour of the military authorities, especially of the Germans, toward the civilian population in the occupied territories was ruthless.

After occupying Russian Poland, the Central Powers divided it into two military occupation zones with a German governor-general in Warsaw and an Austro-Hungarian one in Lublin. The Germans pursued a ruthless requisition policy, carrying off industrial equipment and raw materials and agricultural produce. Several hundred thousand persons were deported to Germany to work there.

The Polish National Committee moved to Petrograd (Leningrad) while their supporters who remained in Congress Poland assumed a passive attitude. A difference of opinions appeared among the supporters of the Central Powers. On Pilsudski's inspiration, in Congress Poland the Polish Socialist Party, the Peasant, and the Democratic groups on Dec. 18, 1915, set up the Central National Committee, which fought against the policy of the Supreme National Committee and opposed further enlistment for the legions until the Central Powers made a decision about the future of Poland.

It was not until the summer of 1916 that, in connection with the loss of all hope for a separate peace with Russia and in view of the need of increasing their military potential, Germany and Austria-Hungary decided to create a Polish buffer state, dependent on them economically, politically, and militarily. On Nov. 5, 1916, the German and Austrian emperors issued proclamations setting up a Polish kingdom on the territory of Congress Poland. The governors-general named on Nov. 26 a provisional council of state of 25 members to represent the Polish people, but only with advisory powers. The council consisted in the main of right-wing supporters of the Central Powers, though the minority included representatives of the Central National Committee as well. Pilsudski became the chairman of the council's Military Board. The Pilsudski group unsuccessfully demanded that he be named commander in chief of the Polish Army and that a Polish government be formed.

On March 27 (new style; old style March 14), 1917, after the overthrow of the Russian imperial regime, the Petrograd Soviet of Workers' and Soldiers' Deputies unanimously recognized Poland's right to independence. The Russian provisional government of Prince G. E. Lvov confirmed this right on March 29 (N.S.; O.S. March 16) but at the same time insisted on a military union of Poland with Russia. Organization was begun of a Polish Army Corps in Russia under the command of Gen. Jozef Dowbor-Musnicki (1867-1937). But in view of the Russian military disinte-

gration and the fear of the radicalism of the Revolution, the Polish leaders who opposed Germany turned their hopes toward the Western Allies. The Polish National Committee in Petrograd was dissolved and several days later, on Aug. 15, 1917, a body under the same name was founded at Lausanne, Switz. Later established in Paris, it was headed by Dmowski; and on Sept. 20 it was recognized by France as the official mouthpiece of Polish interests. Recognitions by Great Britain (Oct. 15), Italy (Oct. 30), and the United States (Dec. 1) followed. Ignacy Jan Paderewski (q.v.) was the committee's delegate in the United States. Meanwhile, on June 4, 1917, a Polish Army had come into being in France. Volunteers, including emigrants from the United States and Canada, enlisted in it.

At a conference in Vienna on March 27, 1917, Austria-Hungary recognized Congress Poland as an area of German influence and placed the legions under the supreme command of the German governor-general. In fear of the Russian Revolution, some of the Conservative supporters of Russia in the Congress Poland associated themselves with the Central Powers. Social radicalism and dislike for Germany grew more intense in the workers' and peasants' groupings. Pilsudski strove for *rapprochement* with the National Democrats who remained faithful to the anti-German line. On July 2, 1917, he left the provisional council of state in opposition to the renewed oath of allegiance given by the legions to the Central Powers. He was arrested on July 22 and interned in Germany. Some of the legionaries were interned and others were incorporated into the Austro-Hungarian Army and dispatched to the Italian front. Those who had given the oath were again placed under the Austro-Hungarian supreme command as the Polish Auxiliary Corps. In the face of the indignation of the people the provisional council of state resigned on Aug. 25. In Galicia, in May 1917, the National Democrats, the Socialists and the Polish Peasant Party had entered into an agreement; the Polish deputies to the Austrian Parliament and the Galician Diet adopted a resolution demanding the creation of "an independent Polish state, comprising all Polish lands with access to the sea."

On Sept. 12, 1917, the Central Powers decided to set up in Congress Poland a regency council, a Polish government, and a council of state of 110 members (half of them elected) as a provisional Parliament. The Regency Council consisted of Mgr. Aleksander Kakowski (1862-1938), archbishop of Warsaw, Prince Zdzislaw Lubomirski (1865-1941), and Count Jozef Ostrowski, a landowner. The first government was formed on Dec. 7 by Jan Kucharzewski (1876-1952).

After the Bolsheviks had taken power Soviet Russia began negotiations with the Central Powers at Brest Litovsk (see BREST-LITOVSK, TREATIES OF). In order to embarrass the Soviet delegation Germany and Austria-Hungary on Feb. 9, 1918, concluded a separate peace treaty with the nationalist Ukrainian government, giving them the Chelm Province, which had a primarily Polish population. This infuriated Polish opinion in all three parts of Poland. On Feb. 27 the Kucharzewski government resigned in protest. The Polish Auxiliary Corps, under the command of Brig.-Gen. Jozef Haller (1873-1960), broke through the front into the Ukraine and joined the units being formed there of Polish soldiers of the former Russian Army.

After a short time the Conservatives resumed their cooperation with the Central Powers. The National Democrats, foreseeing the coming defeat of Germany and Austria-Hungary and fearing Soviet Russia and the increasingly radical Polish Socialist movement, cooperated with the Regency Council in building a Polish administration in Congress Poland. They did not, however, engage in political action together with the occupying powers. The supporters of the interned Pilsudski kept building up the illegal Polish military organization (Polska Organizacja Wojskowa, POW) and were preparing to take power the moment the Central Powers were defeated.

In Belorussia and the Ukraine three Polish Corps were formed but were disarmed during the advance of the armies of the Central Powers to the east. Only the II Polish Corps under Haller was smashed in battle (at Kanev, on the Dnieper), but some of its officers and men reached France where, on Oct. 4, Haller was ap-

pointed by the Polish National Committee to be commander in chief of the Polish Army, recognized by the Allies as "allied and belligerent."

The U.S. Pres. Woodrow Wilson, in his tentative peace message of Jan. 22, 1917, called for the creation of a "united, independent, and autonomous Poland." In a message to the U.S. Congress on Jan. 8, 1918, in his 13th point, he urged the formation of "an independent Polish state" with "a free and secure access to the sea." On June 3, 1918, Great Britain, France, and Italy declared they were in favour of "an independent and united Poland." On Aug. 29, 1918, Soviet Russia abrogated the partition treaties concerning Poland, concluded by tsarist Russia with Prussia and Austria.

F. INDEPENDENCE RESTORED

1. The Reemergence of the State.—In the face of the defeat of the Central Powers the Regency Council on Oct. 6, 1918, issued a manifesto to the nation, declaring the aspiration for an independent and united Poland, the convocation of a *sejm*, and the formation of a representative national government. After negotiations with the National Democrats the Regency Council on Oct. 26 set up a government sympathetic to the Western Allies under Jozef Swiezynski, but on Nov. 3, it dismissed this government. In Galicia, on Oct. 28, in agreement with all the Polish political parties, a "liquidation commission" was set up; and, in view of the disintegration of Austria-Hungary, it assumed power in western Galicia. The moderate Socialist and Peasant parties, with the backing of the Polish military organization, formed a government in Lublin on Nov. 7 with Ignacy Daszynski (*q.v.*) as prime minister. In Congress Poland the left-wing Socialists began forming councils of workers' delegates and advanced a program of socialist revolution.

Released by the German government, Pilsudski arrived in Warsaw on Nov. 10, 1918. On Nov. 11 the German troops in Warsaw and other places of Congress Poland were disarmed. The Daszynski government and the Regency Council turned power over to Pilsudski and dissolved themselves. The Polish liquidation commission in Galicia also subordinated itself to Pilsudski. On Nov. 14, the Supreme People's Council came into being in Poznan as the representative of the Polish people in Prussian Poland, which was still under German control. The National Democrats, adversaries of Pilsudski, had the decisive voice in the Poznan council. On Dec. 27 an uprising against the Germans broke out in Poznan and within a few days it engulfed almost the entire province. On Feb. 16, 1919, an armistice was concluded and a provisional demarcation line was established.

On Nov. 18, 1918, Pilsudski appointed a government that was similar to the Lublin one and was headed by Jędrzej Moraczewski (1870–1944), a Socialist devoted to him. On the left the revolutionary Socialist groupings opposed the government and in December they created the Communist Party of Poland (KPP). On the right, the government was opposed by the National Democrats, who strove to seize power. As provisional head of state, Pilsudski in December began talks with envoys of the Polish National Committee in Paris, Stanislaw Grabski (1871–1949) and Paderewski. On Jan. 16, 1919, he dismissed the Moraczewski government and appointed a new one with Paderewski as prime minister. This government was recognized by the Supreme People's Council in Prussian Poland, by the Polish National Committee in Paris, and by the Allies. On Jan. 26 elections to the *sejm* were held in Congress Poland and western Galicia. The *sejm* elected Pilsudski provisional head of state and reappointed Paderewski as prime minister. The government firmly combated the Communist movement: in June 1919 the councils of workers' delegates were broken up.

Poland's position after World War I was most difficult. The state was coming into being through the unification of three parts which had formerly been incorporated by the partitioning powers. These lands had different levels of political, economic, and cultural development and different traditions. The former Russian and Austrian parts had suffered serious devastation during the war. The industrial plant of Congress Poland had been carried off to a great extent to Russia or Germany; where it remained there was

a lack of raw materials causing widespread unemployment. Agriculture was ruined and a great proportion of the livestock had been requisitioned during the war. Famine reigned and epidemic diseases spread. In various parts of the country there were different currencies (German marks and two types of occupation marks, Austrian crowns, and Russian rubles), but all were of low and uncertain value. A Polish civil administration had existed previously only in Galicia and on a small scale, since 1917, in Congress Poland. The army came into being out of various units: beside Pilsudski's organization, there were Polish units previously formed by the Austrians and Germans, groups of volunteers from former army corps organized in Russia, and then the several classes called up. In April 1919 units of the Polish Army in France returned to Poland.

There were many political groupings, mostly small. The greatest political influence was wielded by the National Democratic Party (ND), which was supported by urban middle and upper classes, the landowners, the clergy, and a considerable proportion of the peasants, especially in the former Prussian Poland. In the former Austrian and Russian part of Poland there was a peasant political movement split up into left-wing groups cooperating with the Socialists and the moderate Polish Peasant Party (PSL) led by Wincenty Witos. Active among the workers were the Polish Socialist Party (PPS) and the Communist Party of Poland. The nationalist workers' organizations united in 1920 as the National Workers' Party. The national minorities organized their own political parties. The left-wing peasant parties, the PPS, and, in part, also the National Workers' Party supported Pilsudski, whom they regarded as a champion of democracy; Pilsudski was opposed mainly by the National Democrats.

In mid-1919, after by-elections, there were 394 deputies in the *sejm*, 140 of them representing the NP and allied groupings, 46 from the PSL, 71 from left-wing peasant parties, 35 from the PPS, 32 from the National Workers' Party, and 13 from the national minorities.

The ND took a firmly anti-German position and through diplomatic contacts tried to obtain the most advantageous Polish-German frontier possible. Its eastern program envisaged the incorporation into Poland not only of all Galicia, including its eastern part inhabited mainly by Ukrainians, but also of areas situated to the east of Congress Poland, though only insofar as they contained major centres of Polish population. This incorporation program planned a progressive polonization of the Belorussian and Ukrainian populations. Pilsudski and the parties supporting him were in agreement with the ND's aspirations for the best possible frontier with Germany, but their foreign policy was definitely anti-Russian: it aimed at separating Belorussia and the Ukraine from Russia and joining these countries and Lithuania with Poland in a federation, with Poland maintaining the leading economic, military, and political role.

Paderewski's government resigned on Dec. 9, 1919, being followed by those headed by Leopold Skulski and, from June 23, 1920, by Wladyslaw Grabski. On July 24, 1920, at a critical moment of the Russo-Polish War (*q.v.*), Witos, with Daszynski as deputy premier, formed a coalition government. (J. Hr.)

2. The Treaty of Versailles and Frontier Problems.—On June 28, 1919, on behalf of Poland, Dmowski and Paderewski signed the Treaty of Versailles, which, however, left the major part of the country's frontiers undefined. Poland regained part of eastern Pomorze and almost all Poznan, but in East Prussia and Upper Silesia the Polish-German frontier was to be decided by plebiscite. Gdansk (*see* DANZIG) was to be a free city under the protection of the League of Nations but was to be included within the Polish customs frontier in order to provide Poland with a free and secure access to the sea; in addition, Poland was to have free, unrestricted use of the port and to undertake the conduct of the free city's foreign relations. There was a Polish-Czechoslovakian dispute over Teschen (Cieszyn or Tesin) and also over the territories of Orawa (Orava) and Spisz. Of the eastern frontiers of Poland art. 87 of the treaty stated that they would be "subsequently determined by the principal Allied and Associated Powers."

East Prussia.—Two plebiscite zones were established, that of Kwidzyn (Marienwerder), an area of 1,036 sq.mi. (2,683 sq.km.) with 174,000 inhabitants, and that of Olsztyn (Allenstein), about 4,800 sq.mi. (12,432 sq.km.) with 565,000 inhabitants. All Prussian civil servants were left in the plebiscite areas and the presence of German security police precluded freedom of speech.

The vote was taken on July 11, 1920, when Soviet forces were at the gates of Warsaw. In the Olsztyn zone 363,209 votes were cast for Germany and 7,980 for Poland, in the Kwidzyn zone 96,923 for Germany and 8,018 for Poland. Making the utmost of a stipulation that not only residents but also persons born in the area had the right to vote, the Germans sent to the plebiscite zones 202,700 "emigrants," who constituted nearly half of the voters, while 40% of the qualified residents abstained from voting. Thus the plebiscite, lost by Poland, could scarcely be described as a fair expression of the popular will.

Upper Silesia.—The plebiscite area of Upper Silesia was 4,250 sq.mi. (472,127 sq.km.) with 1,942,200 inhabitants. Out of 706,820 votes cast for Germany on March 20, 1921, emigrant voters were responsible for 182,288; Poland obtained 479,414 votes. In all, 682 communes voted for Poland and 792 for Germany, but the Poles secured preponderance in the southeastern plebiscite area, which economically was the most important. Disregarding the treaty provisions for the partition of the area according to the wishes of the inhabitants expressed by communes, Germany claimed the whole of Upper Silesia, while Wojciech Korfanty (*q.v.*), the leader of the Silesian Poles and Polish plebiscite commissioner, demanded that 59% of the area, in which 673 communes voted for Poland and 230 for Germany, be awarded to Poland.

The Inter-Allied Commission failed to agree on a unanimous proposal to the Supreme Council of the principal Allied Powers, the British and Italian commissioners favouring cession to Poland of only the two southern agricultural districts of Rybnik and Pszczyna (Pless) while the French commissioner proposed a frontier less favourable than the Korfanty line but leaving the industrial basin to Poland. Learning of this basic disagreement, the Polish military organization, of which Michał Grażyński (1890–) was one of the chief organizers, thought that only an insurrection could save the Polish cause. Korfanty agreed and gave the order for a rising, which broke out on May 3, 1921. In a few days almost all the area within the Korfanty line was occupied. Taken by surprise, the Germans were thrown back. After six weeks' fighting the Inter-Allied Commission effected a cessation of hostilities on June 24, and both the belligerents withdrew their troops.

The Supreme Council assembled in Paris on Aug. 8–12 failed to draw a new frontier across Upper Silesia because David Lloyd George was anxious to save for Germany as much of the industrial area as possible. The only way out of the deadlock was to submit the question to the Council of the League of Nations, where Great Britain was represented by Arthur James Balfour. The council's verdict, given on Oct. 12, 1921, was endorsed by the Allied Powers eight days later. The new frontier divided the industrial area: Poland was awarded 1,241 sq.mi. (3,214 sq.km.) with about 996,000 inhabitants, 76% of the coal production, 22 out of 37 blast furnaces, and 9 out of 14 steelworks. Thus a basis for economic independence was assured. (See also SILESIA.)

Teschen (Cieszyn, Tesin).—On Nov. 5, 1918, close upon the final dissolution of the Habsburg monarchy, the Polish and Czech National Council of Teschen Silesia concluded an agreement dividing the four districts of the province into two ethnographic entities. On Jan. 23, 1919, however, on orders from Prague, the Czech forces fell unexpectedly upon insignificant Polish forces in the area and occupied the greater part of the province. The government of Prague argued that Teschen was historically a Czech land and, moreover, that the new Czechoslovakia needed its coal.

The fighting was stopped by the Supreme Council on Feb. 3, 1919. After a vain attempt to reach agreement by direct negotiation, the Supreme Council decided on Sept. 27 that the dispute should be settled by plebiscite. On July 10, 1920, Poland, whose existence was menaced by the Soviet offensive, agreed at Spa that the Conference of Ambassadors should draw a final frontier. On

July 28 less than half of Teschen Silesia was awarded to Poland (390 sq.mi. [1,011 sq.km.] out of 881 sq.mi. [2,283 sq.km.], with a population of 142,000 out of 435,000). Czechoslovakia secured all coal mines. No Czechs were left on the Polish side of the new frontier, but on the opposite side were 140,000 Poles. The decision relating to Orawa and Spisz was likewise disadvantageous to Poland, which kept 27 villages; the 44 villages awarded to Czechoslovakia had a Polish population of 45,000.

Eastern Galicia.—Of 4,743,000 inhabitants of Eastern Galicia (18,245 sq.mi. [47,255 sq.km.]), Ukrainians formed 52.7%, Poles 39.3%, and Jews 7.2%; there was, however, a considerable Polish majority at Lwow (64% of a population of 300,000) and in some other towns. Enabled by the Austrian authorities to assume control of the whole area, the Ukrainians on Nov. 1, 1918, proclaimed at Lwow (Lvov) an independent republic of the Western Ukraine. Thereupon the local Polish population organized military formations, which succeeded in freeing the city by Nov. 22. In May 1919, after the fighting had continued for six months, the Polish Army occupied the whole of the disputed province.

In March 1919 the Commission on Polish Affairs at the Paris Peace Conference considered the following alternatives regarding the future of Eastern Galicia: (1) a Polish mandate over the whole territory for 25 years, after which its fate was to be settled by plebiscite; (2) partition between Poland and a Ukrainian state. There were alternative demarcation lines in connection with these schemes: line A to run east of Przemyśl, if the whole territory were to be entrusted to Poland under a mandate; and line B, which would leave Lwow and the Drohobycz (Drogobych) oil fields to Poland in the event of the creation of a Ukrainian state. On June 25 the Supreme Council accepted line A and authorized Poland to occupy the whole area; on Nov. 21, it approved the draft of an autonomous statute for the area with a 25-year mandate; on Dec. 22, 1919, giving satisfaction to Polish demands, the Supreme Council rescinded its previous decision and allowed Poland to incorporate the whole area (see also GALICIA).

The Polish-Soviet Frontier.—Under the terms of the Armistice of Nov. 11, 1918, the German Armies had to evacuate western Russia and Poland. As the Germans withdrew, the Soviet Army was advancing westward. In Nov. 1918 it was still on the Dnieper, but by Feb. 1919 had moved forward to the Bug. Soviet Russia needed territorial contact with revolutionary Germany and this could only be won across Poland. The Soviet government hoped, of course, that the Polish workers and peasants would greet its armies as liberators, and was greatly dismayed when they did not. (See also RUSSO-POLISH WAR.)

A counteroffensive launched by the Polish Army under Pilsudski brought the Polish-Soviet front, by the end of 1919, along the Berezina River in Belorussia, and in the Ukraine Novograd-Volynski, Staro-Konstantinov, and Bar were in Polish hands. Although in no haste to decide on Poland's eastern frontiers, the Supreme Council, on Dec. 8, 1919, authorized Poland to organize a regular administration within a temporary line of demarcation "on the territories of the former Russian empire"; i.e., not encroaching upon the formerly Austrian territory of Galicia. The declaration of Dec. 8 stated explicitly that the line fixed was a provisional minimum frontier, without prejudice to later terms which might be designed to fix the final eastern frontier of Poland.

On Jan. 28, 1920, V. I. Lenin, Georgi Chicherin, and Lev Trotsky handed a peace proposal to the Polish government suggesting the actual front as the armistice line. Pilsudski doubted the sincerity of this offer because he had information that the Soviet command was concentrating new divisions on the front and Trotsky himself, in a letter to three prominent French Communists, had written shortly before: "When we have finished with Denikin, we are going to attack the Poles" (*Internationale Communiste*, Dec. 15, 1919). When, however, on March 27, 1920, the Polish government decided to open negotiations the Soviet government's rejection of Borisov, near the front, as a suggested meeting place confirmed Pilsudski's suspicion of a threatened Soviet offensive. On April 21, 1920, he accordingly signed a treaty of alliance with Symon Petlyura (*q.v.*), head of a Ukrainian government at Kamenets-Podolski, and three days later a Polish offensive started

in the Ukraine. (See also UKRAINIAN SOVIET SOCIALIST REPUBLIC: *History*.) On May 7 the Poles occupied Kiev, but on June 8 the Soviet Cavalry under Semen (later Marshal) Budenny broke through the Polish line southwest of Kiev, and on July 4 Mikhail (later Marshal) Tukhachevski attacked north of Borisov. The military situation of Poland became critical. On July 6 W. Grabski, the prime minister, went to Spa, Belg., where the Supreme Council was assembled to ask for immediate help in the shape of war supplies.

With the assent of representatives of France and Italy, the British prime minister Lloyd George undertook to act as mediator. He suggested an armistice along the line of Dec. 8, 1919; in Eastern Galicia the armies were to stand on the line reached on the date of the armistice. Grabski agreed, and on July 11 Lord Curzon, the British foreign secretary, suggested an armistice to Moscow and the Polish Army's withdrawal to the line of Dec. 8, 1919, and in Eastern Galicia to the line A (see above), an obvious discrepancy with the agreement reached the previous day. Thus was born the "Curzon line." (See also SPA, CONFERENCE OF.)

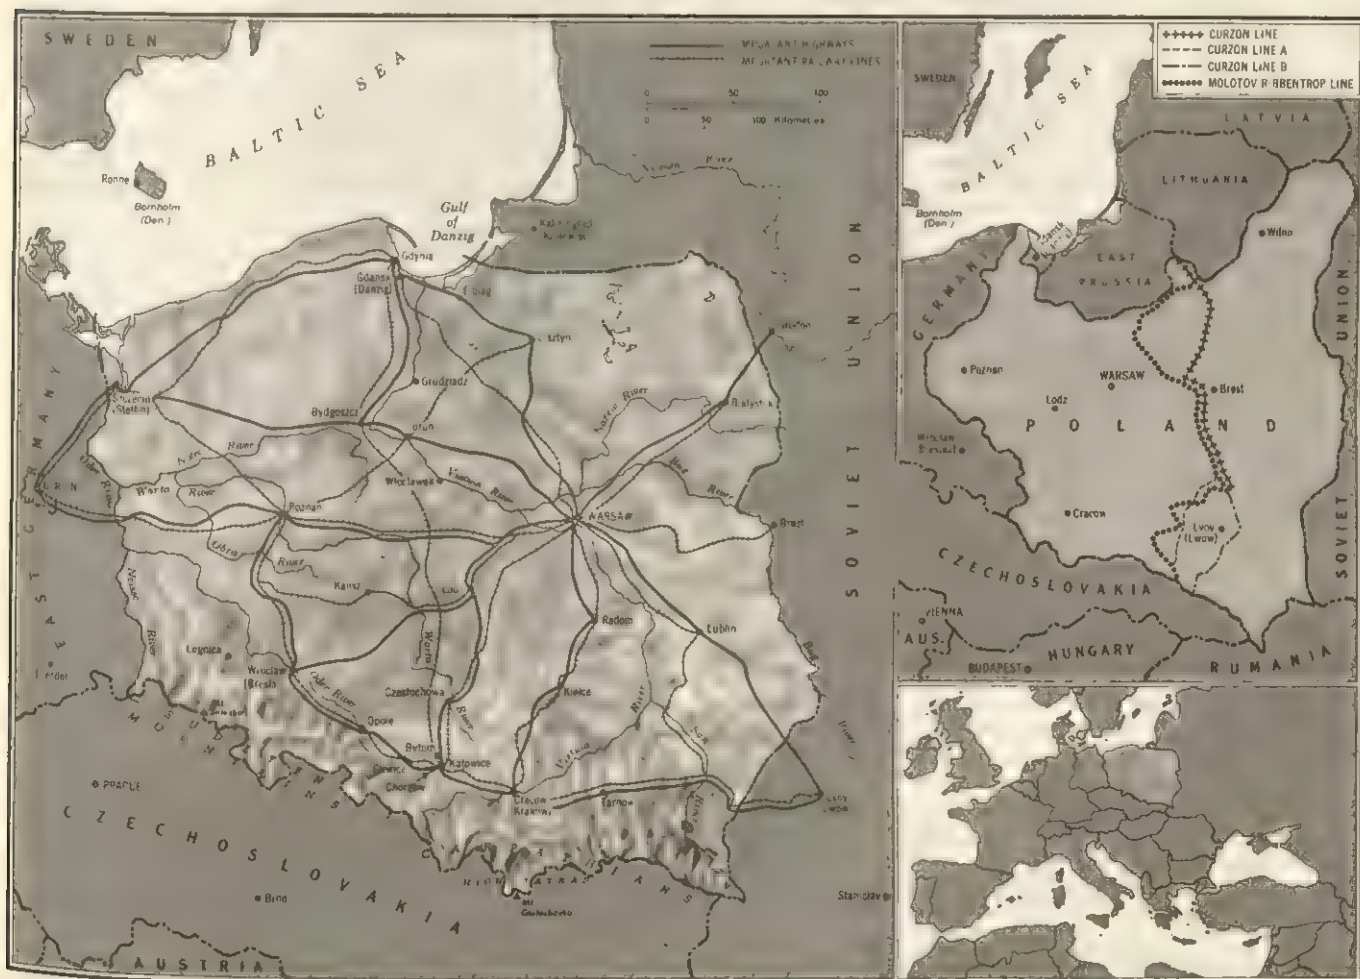

Meanwhile the situation on the front gradually changed. By mid-August Pilsudski's counteroffensive brought a decisive victory. Poland was saved, but not only Poland. "By attacking Poland," said Lenin in Moscow on Oct. 8, 1920, "we are attacking also the Allies. By destroying the Polish army we are destroying the Versailles settlement." A Soviet-sponsored government for "liberated" Poland, headed by Julian Marchlewski, Feliks Dzerzhinski, and Feliks Kon, which had already established itself at Bialystok, had to flee back to Moscow. A Polish-Soviet peace treaty, concluded on March 18, 1921, at Riga, Latvia, added to Poland an area of 51,762 sq.mi. (134,064 sq.km.) E of the line of Dec. 8, 1919.

The Wilno Dispute.—The Polish Army captured Wilno (Vil-

nius) on April 20, 1919, and Pilsudski issued a proclamation suggesting the creation of a federation of Poland with the lands of the former Grand Principality of Lithuania. On July 27 the Supreme Council approved a demarcation line between Poland and Lithuania, leaving Wilno on the Polish side. During the advance of the Soviet armies westward, the Soviet government "ceded" Wilno to Lithuania by a peace treaty signed on July 12, 1920. The city was evacuated by the Russians during their general retreat following the Polish victory and on Aug. 26 was entered by Lithuanian troops. The Poles appealed to the League of Nations and a partial armistice was signed at Suwalki on Oct. 7. Pilsudski was still inclined toward a federal solution of the dispute, with Wilno and its region providing an independent link between Poland and Lithuania. Gen. Lucjan Zeligowski (1865–1947) accordingly occupied Wilno on Oct. 9 and set up a local government. Pilsudski's scheme, however, was incompatible with the prevailing temper of the Poles and Lithuanians. On Feb. 20, 1922, therefore, the democratically elected Regional Assembly of 106 members voted the incorporation of the whole province in the Polish republic; 96 members voted for the incorporation, 6 abstained, and 4 were absent. It remained only to obtain the approval of the principal Allied Powers. The Soviet government had declared in the Riga Treaty its disinterestedness in the Polish-Lithuanian dispute.

The Council of the League of Nations was no longer interested and on Feb. 3, 1923, adopted a final resolution fixing the Polish-Lithuanian line of demarcation. On March 15, 1923, the Conference of Ambassadors, requested by both the Polish and Lithuanian governments to use their right to fix the frontier, recognized the demarcation line of Feb. 3 as the final frontier between the two states.

By the same decision the Conference of Ambassadors recognized

POLAND IN THE 20TH CENTURY: (LEFT) LIMITS OF THE COUNTRY SINCE 1951, SHOWING PRINCIPAL CITIES AND PHYSICAL FEATURES; (TOP RIGHT) POLAND'S BOUNDARY CHANGES BETWEEN 1919 AND 1937 (see TEXT)

as final the Polish-Soviet frontier fixed by the Treaty of Riga. On April 5, 1923, both Polish-Soviet and Polish-Lithuanian frontiers were recognized by the government of the United States. The long series of territorial disputes which handicapped Poland's foreign policy and its internal reconstruction was definitely settled, both legally and in fact. The new Poland had a total area of 150,052 sq.mi. (388,634 sq.km.) with an approximate population of 27,200,000. (K. SM.)

3. Internal Affairs, 1920-26.—The Witos government continued its duties until Sept. 13, 1921, but after the resignation of Daszynski (Jan. 4) it had lost its character of a national coalition. The social and political struggle flared up in the country. In February and March of 1921 there were a railwaymen's strike and a general strike. Particularly acute contradictions appeared in connection with the constitution's being prepared. The left wing in Parliament wanted to stress the role of the president of the republic and expected Pilsudski to be elected to the post. The National Democrats strove for a senate, in addition to the *sejm*, and wanted this chamber to be appointed without general elections.

In the end the constitution of March 17, 1921, was a compromise by both sides and was modeled after the French constitution of 1875. In the Polish republic the legislative power was wielded by the *sejm* and the Senate but the latter had no right to initiate legislation. Both chambers were elected for five years by a system of proportional representation. The *sejm* by a two-thirds majority could dissolve itself before the expiration of its term, but the president could dissolve the *sejm* only with the consent of three-fifths of the Senate. The president and the Council of Ministers were the executive. The president was elected for a seven-year term by both chambers. He nominated and dismissed the prime minister and the ministers, but the government was responsible to the *sejm* and at its demand the cabinet or any minister had to resign. The president promulgated laws and government acts but together with the prime minister and the appropriate minister who bore the full responsibility. He also represented the state externally and was the commander in chief of the armed forces in peacetime, but in wartime, at the recommendation of the government, he had to appoint a commander in chief. The Council of Ministers had the right to initiate legislation.

The president appointed judges who were independent in carrying out the duties of their office. Civic rights were guaranteed. Property was under the care of the state and the abolition or limitation of property by legislation could be effected only with compensation. Citizens had the right to work or to social insurance. Roman Catholicism was accorded a special position, and the state's relations with the church were to be determined in a concordat with the Holy See. Education in state and local government schools was to be free.

Administratively Poland was divided into voivodeships (*województwa*), these in turn into districts (*powiaty*), and the latter into communes (*gminy*). The Silesian voivodeship had partial autonomy and it elected its own local *sejm*. At first the old legislation of the partitioning powers remained in effect in the several parts of the country; gradually, however, unifying work was carried out in the field of judicial administration and codification, but by 1939 it was not completed.

The adopted constitution complicated the solution of the urgent agrarian problem. According to the census of 1921 the landed estates accounted for 47.3% of the total arable land. There were 1,100,000 peasant farms under 2.5 ac. (1 ha.) in size. As early as July 10, 1919, the *sejm* passed a law calling for agrarian reform and on July 15, 1920, during the Russo-Polish War, it passed an act providing for the compulsory partition of the large estates among the peasants. The opponents of that law acted to prevent its implementation by referring to the constitutionally guaranteed property rights. It was not until Dec. 28, 1925, that the *sejm* passed a new law which made provision primarily for voluntary partition of the estates.

In addition to the agrarian question, there was the problem of national minorities. According to the census of 1921 the latter constituted 30.8% of the population, including Ukrainians 14.3%, Jews 7.8%, and Belorussians and Germans 3.9% each. The

Ukrainians, mainly under the influence of nationalist organizations, opposed the Polish government with particular vigour. Among the Polish population there developed anti-Semitism fostered by the National Democrats; among the Jews there grew separatism.

Parliamentary elections were held on Nov. 5-12, 1922. Of the 444 seats in the *sejm*, the ND and its allies won 166, Polish Peasant Party 70, the left-wing Peasant parties 42, the National Workers' Party 18, the PPS 41, the Communists 2, the crypto-Communists 15, the national minorities 81, and others 9. The previous head of state Pilsudski, declined to stand for the office of president in view of its merely representative nature. The votes of the PPS, the Peasant parties and the national minorities elected Pilsudski's old friend, Gabriel Narutowicz (1865-1922), formerly minister of foreign affairs. The ND launched a violent campaign against the president and a week after this election, on Dec. 16, 1922, a sympathizer of this party assassinated him. The same parties which had elected Narutowicz elected a new president, Stanislaw Wojciechowski, on Dec. 20. On Dec. 16 Gen. Wladyslaw Sikorski (*q.v.*) had become prime minister. Pilsudski (a marshal from March 19, 1920) took the position of chief of the general staff.

In 1922 the policy of the Polish Communist Party changed. Its leadership, headed by Maria Koszutska (pseudonym Wiera Kostrzewa; 1879-1939), emphasized patriotic slogans and the movement's need to make its decisions independently. The leadership strove to ease the acuteness of the conflict with the parliamentary left wing and advanced a program, not of direct struggle for a socialist revolution, but of agrarian reform, improvement of the living conditions of the workers, and the strengthening of democracy against the attacks from the right. In 1924 Koszutska and the leaders working with her were removed by the Comintern. From 1925 on, however, they again played a certain role in the leadership of the party.

The steadily growing inflation reached a peak in 1923 and disorganized the life of the country. On May 28, as a result of an understanding between the ND and the PSL, the Witos government took office, and two days later Pilsudski resigned as chief of the general staff, formally retiring from political life. A wave of strikes culminated in a general strike in November, combined with armed uprisings, above all in Cracow (Nov. 6). There was a split in the PSL; the government lost its majority in the *sejm* and resigned on Dec. 14.

The next government was headed by W. Grabski, who also became minister of finance. The government vacillated between the ND and the supporters of Pilsudski. In order to stabilize the currency (74% of budgetary expenditure in 1923 had been covered by the printing of money), Grabski increased tax revenues and cut expenditure. The attempts to make foreign loans brought little result. A British adviser, Edward Hilton Young (later Lord Kennet) was asked to come to Poland, but Grabski did not agree to the formation of a permanent mission of British financial advisers in Poland. On Feb. 1, 1924, a new currency, the zloty, was inaugurated, to be backed up to 30% by gold and hard foreign currencies. On April 28 the Bank of Poland opened its doors: it was a private limited company controlled by the state, with a capital of 100,000,000 zl. subscribed by 52,000 Polish citizens. From February 1925, however, state expenditure again began to exceed the revenues. The economic situation was worsened when in June 1925 Germany began applying trade restrictions against Poland, a move which resulted in both sides engaging in a "tariff war." The inability to overcome the financial crisis induced the Grabski government to resign on Nov. 14, 1925.

While the Grabski government was in office a concordat was signed with the Vatican on Feb. 10, 1925, ensuring for the Roman Catholic Church complete internal freedom with only the nominations to the higher church posts having to be agreed with the government. The church properties were exempted from the agrarian reform. The teaching of religion in state and private schools was organized by the church and the teachers of religion in state schools approved and paid by the state.

Grabski was followed by Aleksander Skrzynski (1882-1931) who formed a government of national coalition. The financial crisis continued, the salaries of state employees were cut, and

treasury notes were printed to cover expenditures. Attempts to obtain foreign loans failed. The PPS ministers opposed the dismissals of workers, the reduction in old age pensions, and the rise in taxes levied on working people; accordingly they left the government, which resigned on May 5, 1926. The government crisis came at a time when there was universal dissatisfaction caused by the instability of the currency, the rise in prices, and also by the endless changes of government.

4. Foreign Policy, 1921-26.—In the first years of Polish independence France's support was Poland's greatest asset. In February 1921 Marshal Pilsudski, as head of state, visited France, and talks led to the signing in Paris, on Feb. 19, of a political agreement. It provided that the two governments should take concerted measures for the defense of their territories if either or both should be attacked without provocation. Circles close to Pilsudski studied the possibility of *rapprochement* with Great Britain, but without success.

Pilsudski also strove to build an alliance of states bordering with the U.S.S.R. on the west. A conference of representatives of Poland, Latvia, Lithuania, Estonia, and Finland, meeting in Helsinki, Fin. (Jan. 15-22, 1920), yielded no results. On March 3, 1921, in Bucharest, Rum., Poland and Rumania signed a treaty of alliance, providing for mutual assistance in the event of an aggression. On March 17, 1922, Warsaw was the venue of the signing of a political treaty by Poland, Latvia, Estonia, and Finland, but it was not ratified by the latter. This treaty envisaged consultation on countermeasures in the event of aggression against one of the contracting countries. The relations between Poland and Lithuania were bad, since Lithuania continued to claim Wilno.

The National Democratic Party wanted to tie Poland with the Little Entente (*q.v.*). This seemed possible after a visit to Prague, Czech., by the Polish foreign minister, Konstanty Skirmunt (1866-1949), and the signing on Nov. 6, 1921, of a political agreement on joint action in the implementation of international treaties signed by both countries. This referred particularly to the treaties of Versailles, Saint-Germain, and Trianon. It was in the interests of Poland to stress the anti-German character of the Little Entente, which had hitherto been directed chiefly against Hungary. In June 1923, the Polish foreign minister, Marian Seyda (1879-), proposed the transformation of the Little Entente into a quadruple alliance with Poland's participation, but he got no support from the countries of the Little Entente. Correct Polish-Czechoslovakian relations, however, were maintained and the Czechoslovakian foreign minister, Edvard Benes, visited Poland in April 1925.

The Dawes Plan was received in Poland with some anxiety as an expression of a desire to rebuild Germany, and this anxiety was deepened by the policy of Gustav Stresemann, linking Germany's power aspirations with *rapprochement* to Great Britain and France. The treaties initialed at Locarno, Switz., on Oct. 16, 1925 and signed in London on Dec. 1 guaranteed the borders of the western neighbours of Germany, but the borders of its eastern neighbours were left without safeguards. The danger was only lessened by two additional treaties concluded at the same time (1) by Poland and Germany on the peaceful settlement of disputes and (2) by France and Poland, giving a French guarantee for the Polish western border.

Locarno weakened the position of the National Democratic Party as an anti-German and pro-French force and strengthened the position of Pilsudski, a statesman with relatively high prestige in Germany. In international and Polish political circles Pilsudski was regarded as being capable of reducing the tension in Polish-German relations and of getting Poland a more advantageous position in the new balance of power.

5. The May Coup d'État and Pilsudski's Rule.—After the fall of Skrzynski's government there was a new understanding between the National Democrats and the PSL and, as in 1923, a government headed by Witos was formed on May 10, 1926. This was a challenge both to Pilsudski and to the left-wing parties. At the head of army units led by his supporters, Pilsudski marched on Warsaw and after fighting on May 12, 13, and 14, he took control of the city. On May 14 the Witos government and Pres. Wojciechowski resigned. In keeping with the constitution Maciej Rataj

(1884-1940), the speaker of the *sejm*, assumed supreme power. The Pilsudski *coup d'état* took place under the slogan *sanacja*, or the moral "cleansing" of society and the state, a fight against corruption, for the restriction of the parliamentary regime, and for the strengthening of the executive power. Pilsudski was backed by the left-wing Peasant parties, by the Socialists, and for several days even by the Communists. The army was split between supporters of Pilsudski and opponents, the latter headed by Gen. Tadeusz Rozwadowski (1866-1928), while General Sikorski remained neutral.

Rataj called to office a government with Kazimierz Bartel (1882-1941) as prime minister and Pilsudski as minister of military affairs. The members of the cabinet were linked with the victorious camp, but they did not belong to any of the large parties supporting Pilsudski. On May 31, 1926, Pilsudski was elected president of the republic by the votes of the parties which backed the coup and of some of the representatives of the PSL who, headed by Witos, were disposed to come to an understanding with Pilsudski. However, Pilsudski refused to accept the election and proposed the candidacy of a prominent scientist, Ignacy Moscicki (*q.v.*), who was elected president on June 1.

One month after the coup Pilsudski inspired a project to change the constitution so as to restrict the power of the *sejm*. The president could dissolve both Houses of Parliament and issue decrees with the force of laws. This second change was opposed by the Socialists, but the constitution was revised by an enormous majority. On Oct. 2, 1926, Pilsudski himself became head of the government, retaining the portfolio of minister of military affairs and, as from Aug. 27, also taking over the office of inspector general of the armed forces, a newly formed post. Socialist and Peasant leaders closest to Pilsudski were also in the government. Two portfolios went to representatives of the Conservative landowners from the eastern regions of the country. On Oct. 25-26 Pilsudski called on the most powerful aristocratic family, the Radziwills, at their estate in Nieswiez. His *rapprochement* with the Conservatives led to a drop in his support from the parliamentary left wing. In September 1927, Col. Walery Slawek (1879-1939), a close friend of Pilsudski, concluded a pact with the Conservatives at Dzikow. The pact provided for the strengthening of the role of the Roman Catholic Church, acceptance of the principle of social solidarity and, in the long run, the introduction of a monarchy. The Polish Socialist Party and the Peasant parties went more and more sharply into the opposition and the groups most closely linked with Pilsudski in 1927 and in 1928 either left these parties or were expelled.

In spite of the tense relations between the *sejm* and the government, Pilsudski did not want to dissolve Parliament before its term of office expired; but he treated it with demonstrative disregard. Presidential decrees restricted the freedom of the press. There were few cases of naked abuse of power, but the authorities disclaimed any responsibility for several political murders and acts of violence against anti-Pilsudski military men and political leaders. The mood of the people was affected by the improvement in the country's economic situation. On Oct. 12, 1929, Poland received an international (mainly U.S.) stabilization loan of \$72,000,000. A stabilization plan was worked out by U.S. adviser, Edwin W. Kemmerer, and another U.S. adviser, Charles S. Dewey, sat on the board of directors of the Bank of Poland. There was an increased influx of foreign capital into Poland. An important development in improving the situation was an enormous increase in coal exports, because of a six-month strike by British miners (1926).

In the elections to the *sejm* on March 4, 1928, the nonparty bloc of Pilsudski's supporters won 130 seats, the National Democrats obtained 37, the Christian Democrats 19, the Polish Peasants 21, the Peasant left wing 66, the National Workers' Party 14, the Socialists 63, the Communists 8, and the national minorities 86 (of which 11 were close to the Communists). The administration supported the government lists and the nonparty bloc received considerable government funds for propaganda purposes. The *sejm* elected as speaker the Socialist leader Daszynski over the Pilsudski candidate, Bartel. However, Bartel formed on June 27

a new government composed almost the same as the previous one.

The struggle between Pilsudski and the *sejm* grew sharper and on March 20, 1929, the *sejm* decided to refer to the High Court of Justice the case of Gabriel Czechowicz, minister of finance, who was charged with having transferred state funds to the non-party bloc before the elections. On April 14 the first so-called "colonels' government" was formed by Kazimierz Switalski (1886-1961). On Oct. 31, when 50 officers in uniform came to the opening of the *sejm*, Daszynski refused to open the meeting.

The left-wing and centre opposition to Pilsudski, from Socialists to Christian Democrats, who had formed the centre-left bloc, with the backing of the National Democrats and the Communists, overthrew the government when the *sejm* session opened on Dec. 5, 1929. This was only a demonstration, since the opposition was aware that the Pilsudski dictatorship could not be overthrown by parliamentary means. The next Bartel government was unable to ease the situation, and a new strong-arm cabinet formed by Slawek on March 29, 1930, aggravated the situation.

On June 29, 1930, the centre-left bloc convened a congress in Cracow and decided to go over to a mass protest campaign. Pilsudski became head of the government on Aug. 23 and Parliament was dissolved on Aug. 30. In September about 70 deputies of the Polish and national minority opposition parties were arrested and the most prominent, including Witos, Korfanty, and the Socialist Herman Liberman (1870-1941), were imprisoned in the fortress of Brzesc (Brest). The persons arrested were subjected to physical maltreatment. At the same time the areas inhabited by Ukrainians were the scene of military "pacification" by searches, economic repressions, and violence.

In the *sejm* elections on Nov. 16, 1930, according to official returns, the nonparty bloc received 44.7% of the votes, gaining 247 seats. The National Democrats won 62 seats, Christian Democrats 15, Polish Peasants 15, left-wing Peasants 33, National Workers' Party 10, the Socialists 24, the Communists 5, and the national minorities 33. From then on the cabinets headed by successive prime ministers (Slawek, Aleksander Prystor, Janusz Jedrzejewicz, Leon Kozłowski, and Slawek again) had a majority in the *sejm* but not enough to change the constitution.

The economic crisis of 1929-33 again engulfed industry and agriculture alike. The value of industrial output in 1932 was only 54% of what it had been in 1928. According to the census of 1931, meanwhile, 21.5% of the workers were unemployed. The prices paid to agricultural producers in 1933 were a mere 40% of those of 1928.

The influence of the formally banned Communist Party grew during the years of the crisis; from 1928, when the Koszutska group had been removed from the leadership, the Communists had cut themselves off even more sharply from the other opposition forces. The centre-left bloc fell apart, the slogans of the Polish Socialist Party became more radical, and so did those of the Peasant Party (SL) which came into being on March 15, 1931, as a result of the unification of all the peasant groups under Witos' leadership. In the right-wing opposition, there were growing reflections of Italian Fascism; these tendencies were represented by those of the National Democrats who, from December 1926, were organized in the Camp for a Great Poland, set up by Dmowski. The activities of all forms of opposition were weakened by the restriction of parliamentary activities, by repressions, and by the censorship of the press.

On Jan. 26, 1934, the nonparty bloc took advantage of the fact that the opposition deputies had walked out of the chamber and, with a dubious interpretation of the rules, passed the draft of a new constitution. With some amendments adopted by the Senate, Pres. Moscicki promulgated it on April 23, 1935. The constitution entrusted supreme power to a president responsible "to God and to history." The legislative powers of the *sejm* and the Senate, as compared to the constitution of 1921, were cut back by the president's right to issue decrees. Both chambers were elected for five years, the *sejm* by a general election: One-third of the senators were appointed by the president, and the manner of election of the remainder was to be specified in an election act. The president called elections for Parliament and dissolved it. He

also exercised executive power and the government was politically responsible to him. If both houses demanded it, the president had to dismiss the government or dissolve Parliament. The candidate for the presidency was chosen by a college of electors, most of whom were to be selected from the deputies and senators. If the outgoing president nominated another candidate, there were general elections, otherwise the candidate of the college of electors became president for a seven-year term.

The constitution made provision for freedom of conscience, speech, and assembly, but made the reservation that the limit of these freedoms was the "common good" of all the citizens. The government could declare a state of emergency with the president's consent and this state was lifted only if the Senate endorsed the *sejm's* bill to this effect.

6. Pilsudski's Successors—On May 12, 1935, Pilsudski died at the age of 68. His death caught the government camp at a time of increased pressure by the opposition. In 1935 the Communists called for a popular front and defense of the independence of Poland against the menace from Nazi Germany; and these slogans evoked a response from the left-wing Socialists and some Peasant leaders. The leadership of the PPS and the Peasant Party rejected an alliance with the Communists, but the antigovernment agitation was intensified. In 1936 and 1937 the country was swept by a wave of political demonstrations and strikes by workers and peasants. Among the intellectuals, the campaign conducted by the Communists and left-wing Socialists was joined even by some writers and scientists who had previously been under the spell of Pilsudski. The activity of the Polish Communists, however, decreased from the end of 1936 in connection with the arrest of their leaders in the U.S.S.R. In March 1938 acting on Stalin's orders, the Comintern dissolved the Communist Party of Poland, branding its leaders as provocateurs and agents of capitalist intelligence services. Many of them were shot.

On the extreme right, on March 17, 1934, the National Radical Camp (ONR) came into being; in the same year it was dissolved by the government, but it continued its activities in two factions. It took up the totalitarian slogans and acquired an overwhelming influence among the university students. Sikorski, Paderewski, Haller, and Witos strove to create a bloc of moderate opposition forces and were particularly active in this respect in 1936-38, but with no result worth mentioning. The Ukrainian movement, which was primarily nationalist, grew more intense even though the government tried to suppress it by new "pacifications."

In the fight for the political heritage of Pilsudski were Pres. Moscicki, Gen. Edward Smigly-Rydz (1886-1943), inspector general of the armed forces, and Slawek, the leader of the nonparty bloc, which had been dissolved on Oct. 30, 1935. Before the dissolution of the bloc, elections had been held. The new electoral law for the *sejm* restricted the nomination of candidates; and for the Senate only citizens with higher education or an officer's rank, teachers, and members of certain institutions were to be eligible. The opposition parties boycotted the elections. On Sept. 8, 1935, according to the official returns, 45.9% of the electorate cast their votes, the figure for Warsaw being only 29.4%. It was generally felt that the elections had been falsified.

Moscicki appointed a government headed by Marian Zyndram-Kosciolkowski (1892-1946); and on May 15, 1936, after an understanding with Gen. Smigly-Rydz, he named a cabinet headed by Gen. Felicjan Slawoj-Skladkowski (1885-1962), which remained in office until September 1939. On July 15, 1936, there appeared a government circular which declared that Smigly-Rydz, "in keeping with the will of the President," was his first collaborator, to whom the government and state officials should give obedience. On Nov. 10, 1936, Smigly-Rydz was made a marshal.

In June 1936 the ruling groups called to life the Camp of National Unity (OZN). Slawek was ignored, but there were sharp differences between Moscicki and Smigly-Rydz. The presidential group tried to ease the opposition on the part of the Peasant Party. The head of the Camp, Col. Adam Koc (1891-), and Smigly-Rydz decided in 1937 to enter into an alliance with the right wing of the National Radical Camp. However, this alliance soon disintegrated.

In the years 1935-39 there was an improvement in the economic situation. Eugeniusz Kwiatkowski (1888-), minister of finance, implemented a policy of a moderate planned economy. By mid-1936 the government published a four-year investment plan. The main aim was to build a central industrial region in the San-domierz area to work primarily for national defense. This caused some rise in employment, but the economic balance sheet in industrial and agricultural production was finally still unsatisfactory. In many branches of industry less was produced in 1938 than in 1913, though new industries had been developed; and agricultural production was stagnant. Implementation of the agrarian reform lagged far behind the timetable foreseen in the act of 1925.

7. Foreign Policy, 1926-39.—After the May *coup d'état* of 1926, Pilsudski influenced Poland's foreign policy. He suggested that August Zaleski (1883-) should be the foreign minister, and the latter kept this portfolio for more than six years. The Franco-Polish alliance was maintained, though some loosening of it resulted from repeated attempts, both from Berlin and from Paris, at a Franco-German reconciliation. In September 1926 Germany joined the League of Nations, with a permanent seat in its council. Poland demanded the same privilege, but obtained only a semipermanent seat. The Polish government tried without success to achieve a *détente* with Germany as well as to increase contacts with Great Britain. Poland signed the Kellogg-Briand Pact of July 24, 1929, considered as a sort of additional guarantee against German aggression.

Soviet-Polish relations became strained after Pilsudski's return to power, but a *détente* followed when on Feb. 9, 1929, Poland, Rumania, Latvia, and Estonia signed with the U.S.S.R. a protocol outlawing wars of aggression. On July 25, 1932, a five-year Polish-Soviet nonaggression treaty was signed; and in December 1934 it was prolonged for ten years. Zaleski resigned on Nov. 2, 1932, and was succeeded by Col. Jozef Beck (*q.v.*), formerly Pilsudski's *chef de cabinet*. A Polish-German ten-year nonaggression treaty was concluded with Germany on Jan. 26, 1934. There was of course a reservation that the new treaty was not to affect Poland's previous engagements, particularly its alliance with France.

After Pilsudski's death (May 12, 1935) Beck continued his master's difficult policy of holding the balance between the U.S.S.R. and Germany. When on March 7, 1936, Hitler reoccupied the demilitarized zone of the Rhineland, violating the treaties of Versailles and of Locarno, Poland assured France that it was ready to fulfill the duty of an ally. During the critical year 1938 Poland twice declared its readiness to use force to settle local disputes: on March 17 it demanded and obtained from Lithuania the establishment of normal diplomatic relations (*see LITHUANIA: History*); and on Sept. 30 it demanded and obtained from Czechoslovakia the cession of that section of the Czech part of Teschen Silesia in which Polish population remained predominant (*see above*).

From October 1938, Germany increased its political pressure on Poland, demanding consent to the annexation of the Free City of Gdansk to the *Reich* and the construction of extraterritorial highways between the *Reich* and East Prussia across Poland. Regarding these demands as the first step toward the subjugation of Poland to Germany, the Polish government rejected them. On March 31, 1939, Neville Chamberlain, the British prime minister, speaking also on behalf of France, announced that Poland would receive help if its independence were threatened. Beck went to London and after talks with him Chamberlain said on April 6 that Poland and Great Britain would conclude a treaty of mutual assistance. During the talks Beck gave the assurance that the Polish government treated the pledge of mutual assistance as a bilateral one. On April 28 Hitler abrogated the nonaggression treaty with Poland. The Germans started organizing provoking incidents in Gdansk and on the Polish-German frontier.

The military negotiations between Great Britain, France, and the U.S.S.R. in Moscow in August were broken off when Poland rejected the proposal that Soviet troops should march across its territory in the event of a conflict with Germany. On Aug. 23, in Moscow, Joachim von Ribbentrop, the German foreign minister, and V. M. Molotov, the Soviet people's commissar for foreign af-

fairs, signed a nonaggression treaty. A secret protocol provided, in the event of "a territorial and political transformation of the territories belonging to the Polish state," for mutual respect of the spheres of interest bordered by the Pisa-Narew-Vistula-San line. On Aug. 25 a Polish-British treaty of alliance was signed in London.

G. POLAND DURING WORLD WAR II

On Sept. 1, 1939, without declaration of war, German troops marched into Poland from the north, the west, and the south. Two days later, Great Britain and France declared war on Germany. The Polish forces, weaker numerically and technically, were overcome by the German superiority of arms in spite of fierce resistance. By mid-September the main Polish forces were smashed, Warsaw was surrounded, and German troops were occupying Bialystok and Brest and approaching Lwow (Lvov). On Sept. 17 Soviet troops crossed the eastern Polish border without encountering any notable resistance. Pres. Moscicki, the commander in chief, Marshal Smigly-Rydz and the government, who had left the capital on Sept. 6 and 7, entered Rumania, where they were interned. Encircled Warsaw, bombed from the air and bombarded by artillery, surrendered on Sept. 27 after heroic resistance by the army, backed by the civilian population. The Polish campaign was ended on Oct. 5, when the group of Gen. Franciszek Kleeberg capitulated near Kock, southeast of Warsaw.

In a protocol signed in Moscow on Sept. 28, 1939, Ribbentrop and Molotov established a new border between the Soviet and German spheres of interests. On the territory which had hitherto belonged to the Polish state it ran along the San and Bug rivers, and then westward of Bialystok. The Germans annexed to the *Reich* that part of the occupied territories which included Poznan, Gdynia, Bydgoszcz, Katowice, Lodz, and Plock, while the rest was set up as a *General-Gouvernement* with four districts—Cracow, Warsaw, Lublin, and Radom. The governor-general, Hans Frank, resided in Cracow. About 1,000,000 Poles and Jews were deported from the annexed territories, primarily into the *General-Gouvernement*. Part of the population was deported to Germany to do forced labour or concentrated in special "reserves." With the Jews, mainly townspeople were deported. The Polish population which was left, chiefly in Pomorze and Silesia, was subjected to a policy of germanization. At the same time the lands annexed to the *Reich* were settled by more than 700,000 Germans.

In the *General-Gouvernement* the administration was in German hands. Polish secondary schools and institutions of higher learning were closed. The teaching of Polish history and the history of Polish literature in primary schools was forbidden. However, clandestine education was conducted at all levels. From the very first days of the occupation persecution of the Poles began. On Dec. 27, 1939, there was a mass execution of civilians at Wawer near Warsaw. In November 1939 several dozen professors of the University of Cracow were sent to concentration camps, where some of them died. In June 1940 prominent political leaders—among them Rataj and the Socialist leader Mieczyslaw Niedzialkowski (b. 1893)—were shot; and the infamous concentration camp was set up at Oswiecim (Auschwitz). Other camps were also established.

The area occupied by the U.S.S.R. was annexed to Soviet Belorussia and the Ukraine; the territories bordering on Lithuania, including Wilno (Vilnius), were transferred to it, but on Aug. 3, 1940, Lithuania was declared a constituent republic of the U.S.S.R. Mass deportations carried Poles deep into the U.S.S.R., often at random, though in principle these measures were to involve persons suspected of political activity and employees of the former Polish administration. Some Polish professors, however, were allowed to lecture at institutes of higher learning.

After the German invasion of the U.S.S.R., Eastern Galicia was joined to the *General-Gouvernement*. The Bialystok region was incorporated into the *Reich*. The remaining eastern provinces which had belonged to Poland until 1939 were later incorporated into the *Reichskommissariat Ukraine* and *Reichskommissariat Ost*. Immediately upon entering these provinces the Germans began to persecute Poles and Jews there, and in this they received sup-

port from Ukrainian nationalist organizations. In Lwow, 21 professors of the university and the higher school of engineering were shot in July 1941.

It is estimated that the death of more than 6,000,000 persons was caused by the Germans within the 1939 Polish frontiers. More than 600,000 died directly as the result of military operations, including about 500,000 civilians. Of the persons murdered 3,200,000 were Jews. As early as October 1939 the Germans began to organize walled ghettos for the Jews in the towns. From autumn 1941 to autumn 1943 nearly the entire Jewish population was transported to death camps. In the face of the danger of extermination, the Warsaw ghetto on April 19, 1943, took to arms, and this rising was suppressed only after three weeks of bitter fighting. Jews from Poland were taken to be exterminated at Oswiecim-Brzezinka, Majdanek, Chelmno, Treblinka, Belzec, and other camps. Poles were sent to camps at Oswiecim-Brzezinka, Majdanek, Ravensbrück, Sachsenhausen, Dachau, Stutthof, and elsewhere. About 200,000 Polish children from 6 to 10 years of age, who were classified as "racially valuable," were sent to the *Reich* and subjected to germanization. Approximately 2,500,000 Poles were taken to Germany for forced labour.

After the campaign of 1939, a Polish government in exile was set up in France. Pres. Moscicki, interned in Rumania, appointed Wladyslaw Raczewicz (1885-1947) as his successor. Gen. Sikorski became commander in chief of the Polish Army formed in France out of wartime refugees from Poland and other Poles abroad. He also became prime minister of the government, which represented all political parties and allowed greater influence than before to the prewar opposition. The Polish Army in France amounted to about 85,000 men. One brigade took part in the Battle of Narvik during the Norwegian campaign, two divisions fought in Champagne and Lorraine during the French campaign of 1940. After the fall of France, the Polish government and about 20,000 soldiers managed to get to Great Britain. Polish airmen took part in the Battle of Britain. A Polish brigade which came into being in Syria in 1940 passed to Palestine after the capitulation of France. In 1941 it took part in the fighting in Egypt and Libya, including the defense of Tobruk.

The Polish underground resistance movement began to take shape immediately after the defeat in 1939. On Sept. 27 the Victory of Poland Service came into being, and in January 1940 it was transformed into the Union for Armed Struggle. Political parties began illegal activities. In August 1940 a delegate of the London government in exile was appointed in Poland. The resistance movement soon began sabotage and subversive activities.

Shortly after the German attack on the U.S.S.R., a Polish-Soviet agreement for cooperation during the war and for the creation of a Polish Army in the U.S.S.R. was signed in London on July 30, 1941. The Soviet government declared that the Soviet-German agreements of 1939 dealing with territorial changes in Poland were no longer valid. On Aug. 14, 1941, a Polish-Soviet military convention was signed in Moscow, and the organization of an army started under the command of Gen. Wladyslaw Anders (*q.v.*). On Dec. 4, 1941, in Moscow, Sikorski and Stalin signed a declaration on the participation of the Polish Army in the fighting on the eastern front. The army was to consist of six divisions, and in February 1942 it comprised about 75,000 men. The misunderstandings between the Soviet authorities and the Polish Army Command, which had existed from the beginning, grew more acute in 1942. In March and April part of the Polish Army was transferred to the Middle East and in August the remainder left the U.S.S.R. The relations between Sikorski's government and the Soviet government deteriorated further. In April 1943 the Germans announced the discovery of mass graves at Katyn Forest near Smolensk and accused the Soviet authorities of having murdered about 14,300 Polish officers there in April 1940. The Soviet government maintained that these officers had been murdered by the Germans when they occupied the Smolensk area in autumn 1941. Sikorski's government asked the International Red Cross to carry out an investigation, but this was turned down. On April 25, 1943, the Soviet government severed diplomatic relations with the Polish government in London, since it regarded that govern-

ment's attitude on the Katyn affair as hostile to the U.S.S.R.

On July 4, 1943, Sikorski died in an aircraft crash near Gibraltar. The new prime minister was Stanislaw Mikolajczyk (1901-66), leader of the Peasant Party, and the new commander in chief was Gen. Kazimierz Sosnkowski (1885-). The Polish Army that had been evacuated from the U.S.S.R. was reformed in Iraq and Palestine; and as the II Corps it took part in the fighting in Italy from May 1944. A Polish Armoured Division in Great Britain (under Gen. Stanislaw Maczek) participated from August 1944 in the fighting on the western front, including the Battle of Falaise. A Polish parachute brigade (under Gen. S. Sosabowski) took part in the Arnhem operation.

On the Soviet government's severance of diplomatic relations with the Polish government in London, the Union of Polish Patriots, led by the Communists Wanda Wasilewska (1905-64) and Alfred Lampe (1900-43), came into being in the U.S.S.R. at the end of April 1943. The formation of a Polish division began under the command of Gen. Zygmunt Berling (1896-), formerly chief of staff of 5th Division in the Anders Army. This division was transformed into an army corps in August 1943 and into the 1st Polish Army in March 1944. In October 1943 the 1st Polish Division distinguished itself in fighting at Lenino, near Mogilev.

The rupture between the Soviet government and the Polish government in London brought up the question of the future Polish-Soviet frontier, which had not been raised officially before. At the Teheran conference (Nov. 28-Dec. 1, 1943) Franklin D. Roosevelt, Winston Churchill, and Stalin began to concert the views of the Allied Powers on this matter. On Feb. 2, 1944, in the House of Commons, Churchill spoke in favour of transferring the lands east of the Curzon line (*see above*) to the U.S.S.R. and of compensating Poland with territory in the west and the north.

The London government's delegate in Poland, Jan S. Jankowski (1882-1953) on April 26, 1944, was appointed deputy premier of that government. Three other ministers were appointed, and together with Jankowski they constituted the Home Council of Ministers, which had the Council of National Unity, representing all political parties, as its advisory body. The Union for Armed Struggle became the Home Army under the command of Gen. Stefan Rowecki (1895-1944), known as Grot, on Feb. 14, 1942, and under that of Gen. Tadeusz Komorowski (1895-1966), known as Bor, after Rowecki's arrest. The armed organizations of parties associated with the London government, which previously had been independent, also joined the Home Army.

In January 1942 Polish Communists founded the Polish Workers' Party (Polska Partia Robotnicza or PPR), which undertook a political struggle against Germany. The successive secretaries-general of the PPR were Marcei Nowotko (1893-1942), Pawel Finder (1904-44) until his arrest in November 1943, and finally, Wladyslaw Gomulka (*q.v.*). In May 1942 the People's Guard, the military organization of the PPR, began action. The People's Guard, and in its footsteps the Home Army, developed more and more intensive guerrilla warfare against the Germans from mid-1942 and especially from spring 1943. On Jan. 1, 1944, on the initiative of the PPR, the National Home Council came into being under the chairmanship of Boleslaw Bierut (1892-1956) and with the participation of the left-wing Socialists and some leaders of the Peasant and Democratic parties. At the same time the People's Army was organized under the command of Gen. Michal Zymierski (1890-), known as Rola. Its core consisted of the previous People's Guard.

When the Soviet Army, with the Polish Army formed in the U.S.S.R., crossed the Curzon line on July 21, 1944, the Polish Committee of National Liberation (PCNL) was established; and when the Germans were driven out of Lublin, that city became its seat. In a manifesto on July 22 the PCNL declared itself the sole legal Polish executive power and proclaimed that the constitution of 1921 was in force. It called for a continued struggle against Germany in alliance with the U.S.S.R., for settlement of the Polish-Soviet frontier according to the principle of nationality, and for a westward realignment of the Polish-German frontier. The committee announced the restoration of democratic rights, agrarian reform, and the introduction of provisional state administration

of heavy industry. On July 22 a decree united the Polish Army in the U.S.S.R. and the People's Army into a single force.

On Aug. 1, 1944, the Home Army began a rising in Warsaw in an effort to take over the city before the Soviet Army could occupy it. However—either as a political maneuver or because of German resistance (an issue still debated)—the Russians failed to relieve the Polish home army. The insurgents found themselves in a disastrous situation. The Germans gradually reconquered the city, bombarding it from the air and by artillery fire. The insurgents and the civilian population were murdered or deported to concentration camps or to forced labour in the *Reich*. After a heroic resistance of more than two months Warsaw capitulated on Oct. 2. The insurgents, with their commander in chief, were taken prisoners; the entire population of the city was evacuated and the city itself almost totally gutted by fire.

Mikolajczyk visited Moscow early in August 1944, but his negotiations with Stalin and with the PCNL did not lead to any understanding; equally inconclusive were the negotiations during Mikolajczyk's next visit in October, when Churchill was in Moscow. On Nov. 24 Mikolajczyk resigned and a new London government was formed by an opponent of negotiation, Tomasz Arciszewski (1877–1955), a senior Socialist leader who until July 1944 was the chairman of the underground Council of National Unity in Warsaw.

H. THE PEOPLE'S REPUBLIC

Poland came out of World War II with enormous losses of population, industry smashed, and agriculture devastated. Warsaw had almost ceased to exist. The people were divided between rival political camps. A consolidating bond, however, was the hatred felt for the Germans. There was general approval for the battles fought by the Polish forces in the final stages of the war, first on lands to be incorporated into Poland, later in Germany proper till Berlin was captured. In these final stages, two Polish armies of about 150,000 men fought alongside the Soviet forces.

The PCNL was composed of Communists, left-wing Socialists, left-wing Peasant leaders, and representatives of the Democratic Party. It was headed by the left-wing Socialist, Edward Osobka-Morawski (1909–). The National Home Council functioned as the provisional Parliament. On Dec. 31, 1944, the PCNL was transformed into a provisional government. The decisive role was played by the PPR, led by Gomulka who became deputy premier. After the winter offensive by the Soviet forces the provisional government took control of all of Poland in the early months of 1945. Political groups connected with the government in London remained partly underground; some took up arms. Gen. Leopold Okulicki (1898–1946), who had succeeded Komorowski as commander in chief of the Home Army, Jankowski, and their ten colleagues were arrested on March 20, 1945, by the Soviet military authorities on charges of conducting armed action against them. They were tried in Moscow on June 21; Okulicki was sentenced to ten years' imprisonment, Jankowski to eight, the others to terms varying from five years to four months.

1. The Provisional Government of National Unity.—At the Yalta conference in February 1945, Roosevelt, Churchill, and Stalin decided that a new "Polish Provisional Government of National Unity" should be formed, based on the existing provisional government (which on Feb. 1 had moved from Lublin to Warsaw), but also including "other Polish democratic leaders from Poland and from abroad"; then democratic elections to the *sejm* should be held as soon as possible. Only a small part of the Polish émigré leaders took part in the roundtable conference which began in Moscow on June 17. On June 28 a Provisional Government of National Unity was formed with 16 ministers from the old provisional government and five new ones, with Osobka-Morawski as premier and Gomulka and Mikolajczyk as deputy premiers. In the reorganized presidium of the National Home Council, Bierut remained president, and Wincenty Witos (who died shortly after) and Stanislaw Grabski became vice-presidents. On July 5 the new government was recognized by the United States and Great Britain, who withdrew their recognition from the London government. However, this government tried to continue its activities.

2. The New Frontiers.—In February 1945, at Yalta, the Allied Powers established in principle Poland's eastern frontier more or less identical with the Curzon line. On Aug. 16, 1945, in Moscow, Poland and the U.S.S.R. signed a treaty demarcating the new Polish-Soviet frontier. The overwhelming proportion of the Polish population on Soviet territory moved to Poland. Small changes in the Polish-Soviet frontier were made on Feb. 15, 1951.

On Aug. 2, 1945, in Potsdam, U.S. Pres. Harry S. Truman, Clement Attlee, and Stalin issued a declaration establishing a new *de facto* western frontier of Poland along the Oder and Lusatian Neisse rivers. Poland took over the administration of lands previously held by Germany to the east of this line, with the exception of the northern part of East Prussia, which was incorporated in the U.S.S.R. Gdansk was also turned over to Poland. Like Czechoslovakia and Hungary, Poland was authorized by the Potsdam conference to transfer the German population to Germany (for details see *GERMANY: History: Germany After World War II, 1945–49*). On July 6, 1950, the Oder-Neisse frontier was recognized as final in a treaty signed in Zgorzelec (Görlitz) by the German Democratic Republic and Poland. The Polish-Czechoslovakian frontier was identical with that of July 28, 1920; in other words, the disputed territories taken by Poland in 1938 were restored to Czechoslovakia. Poland's territory was reduced in the east by 69,290 sq.mi. (179,460 sq.km.), and increased in the west and north by 39,597 sq.mi. (102,556 sq.km.), the new area amounting in all to 120,359 sq.mi. (311,730 sq.km.).

3. Social and Economic Reforms.—The PCNL undertook fundamental social reforms. The major industrial establishments which had been under German management during the war were put under Polish state management. On Sept. 6, 1944, the committee issued a decree on land reform, which was implemented immediately in the territory under the committee's power and subsequently by the government for the rest of Poland. Farms of more than 123.5 ac. (50 ha.) of arable land and farms of more than 247 ac. (100 ha.) overall size were subject to expropriation without compensation. Former German farms and farms left by Ukrainians who were repatriated to the U.S.S.R. were taken over for the agrarian reform as well. Peasants, chiefly smallholders, and agricultural workers received 5,891,000 ac. (2,384,100 ha.) in the old Polish territories and 9,107,000 ac. (3,685,600 ha.) in the new ones. Forests were nationalized, and part of the arable land of the former private estates became state farms. On Jan. 3, 1946, the National Home Council passed a bill nationalizing those industrial establishments which employed more than 50 workers per shift and all former German property. The settling of the new western and northern territories, partly with Polish people from prewar eastern territories, started immediately after the war. The reconstruction of Warsaw began.

On Nov. 10, 1945, the Central Planning Office was set up; it was transformed into the State Planning Commission in 1949 and into the Planning Commission of the Council of Ministers in 1956. On Sept. 22, 1946, the National Home Council promulgated a three-year plan for economic reconstruction (1947–49).

4. Internal Affairs, 1945–48.—The Provisional Government of National Unity consisted of representatives of all legally authorized political parties. In addition to the Polish Workers' Party (PPR), the Polish Socialist Party (PPS, with some Socialists who had previously collaborated with the London government), the Peasant Party, and the Democratic Party, there were also the new Polish Peasant Party (PSL) led by Mikolajczyk and the Christian-Democratic Labour Party. While remaining in the government, the PSL enjoyed the support of all the legal and illegal opposition forces. On Aug. 2, 1945, the government issued a decree of amnesty for all members of illegal military and political organizations. More than 44,000 persons took advantage of this amnesty. However, some members of the illegal organizations remained in the underground, concentrated chiefly around the Association for Freedom and Independence, set up in place of the Home Army. The illegal groups, with a membership of about 22,000, carried on propaganda activities and some terrorist activities as well. Apart from these, there were nationalist Ukrainian groups with about 6,000 members.

The Democratic bloc, consisting of the PPR, the PPS, the Peasant Party and the Democratic Party, favoured close cooperation with the U.S.S.R. and the introduction of a socialist system. The PSL gravitated toward the Western Powers and the retention of the capitalist system, though officially it supported the land reform and nationalization of industry as envisaged by the decisions of 1944 and 1946. On June 30, 1946, a referendum was held. The Democratic bloc urged voters to vote "yes" for three questions: "Are you for the elimination of the senate?"; "Do you want the future constitution to consolidate the economic system introduced by the land reform and to nationalize the basic branches of the national economy, with private business retaining its legal rights?"; and "Do you want the consolidation of the western borders of the Polish state on the Baltic, and the Oder and the Lusatian Neisse rivers?" The PSL urged a "no" vote only to the first question, the illegal organizations a "no" vote to the first two questions. According to the official returns, 80.8% of the voters went to the polls, and 68.0%, 77.2%, and 91.4% voted "yes" for the three questions, respectively. Just before the referendum a small group of leaders left the PSL to create a new Peasant Party close to the Democratic bloc, while the strong minority in the PSL, led by Czeslaw Wycech and Jozef Niecko, demanded an easing of the opposition line. The struggle between the PSL led by Mikolajczyk and the Democratic bloc, however, grew sharper.

Elections to the *sejm* took place on Jan. 19, 1947. The PPR and the three parties allied with it came out with a joint list for the Democratic bloc. The main opponent, and in many areas the only opponent, of the bloc was the PSL. The official returns were that 89.9% of the voters took part in the elections, and 80.1% of the votes were cast for the Democratic bloc. On Feb. 5, the new *sejm* elected Bierut president of the republic. The new government was headed by Jozef Cyrankiewicz (1911-) of the PPS, Gomulka becoming deputy premier; the most important posts in the government were given to the former ministers representing the Democratic bloc. On Feb. 19 the *sejm* passed the so-called "Small Constitution." In addition to the president and the government, executive power was to be exercised by a Council of State, comprising the president, the marshal (speaker) and deputy-marshals of the *sejm*, the president of the supreme audit chamber, and possibly other members elected by the *sejm*. The Council of State supervised the territorial local people's councils and approved government decrees issued as laws on the basis of powers given to the government by the *sejm*. On Feb. 22 the *sejm* adopted a new amnesty, of which many members of illegal political and military organizations took advantage. Backed by the Democratic bloc, opposition to Mikolajczyk within the PSL increased; and on Oct. 21, 1947, in danger of being arrested on charges of cooperation with illegal organizations, Mikolajczyk fled to England with the U.S. ambassador's help. The opposition within the PSL took over the leadership of that party, which from then on played little role in Polish political life.

5. The Eclipse of Gomulka, 1948-55.—In the first months of 1948 preparations began for the unification of the PPR and the PPS. These preparations ran into opposition on the part of the Socialists, who wanted to maintain the independence of their party and had hitherto treated cooperation with the PPR as a necessity. They were also distrustful of the Soviet system of government and were afraid of its being transferred to Poland. Gomulka emphasized the necessity of the political link with the U.S.S.R., but also the need of independent internal policy and the importance of the tradition of independence in the Polish Workers' Movement. He accepted the formation of the Communist Information Bureau, known as Cominform (see COMMUNISM), in September 1947 with reservations, but in 1948 he opposed the condemnation of Yugoslavia and the beginning of the collectivization of agriculture in Poland. Gomulka was removed from the post of secretary-general of the PPR, and on Sept. 3, 1948, his place was taken by Bierut. The Cominform's recommendations were accepted in full and a purge took place in the PPS. On Dec. 15, 1948, the PPR and the PPS merged into the Polish United Workers' Party (*Polska Zjednoczona Partia Robotnicza* or PZPR) led by Bierut.

The merger Congress adopted the basic economic premises of the 1950-55 six-year plan which was later approved by the *sejm*. The plan provided for the rapid industrialization of the country, especially the extension of heavy industry. During these six years the economic reconstruction of formerly German lands east of the Oder-Neisse line was in principle completed. The rapid industrialization, however, took place in part at the expense of a reduction in the standard of living: rises in wages and salaries did not compensate for the rises in prices for some groups of working people. The countryside moreover was burdened with compulsory deliveries to the state; and as the prices paid were kept low these deliveries constituted a form of tax in kind. On Oct. 28, 1950, a drastic currency revaluation was introduced: savings accounts and all bank deposits up to 100,000 zlotys were revalued at the ratio of 100 to 3; wages and prices were reduced at the same ratio; but all deposits over 100,000 zlotys were exchanged at the rate of 100:1. In the countryside collectivization under administrative pressure yielded small results: by the end of 1953 there were about 8,000 producers' cooperatives owning 9% of arable land, and agricultural production was stagnant. The one-sided expansion of heavy industry and the situation in agriculture led to an undermining of the market equilibrium, most markedly in the years 1951-53.

Within the ruling PZPR the main decisions were made by a political bureau of about a dozen persons. In addition to Bierut the greatest influence was wielded in the bureau by Jakub Berman (1906-) and Hilary Minc (1905-). Gomulka and his closest friends, Gen. Marian Spychalski (1906-) and Zenon Kliszko (1908-), were removed from the bureau in November 1949; and in July 1951 they were arrested. Marshal Zymierski, the minister of national defense, resigned on Nov. 6, 1949, and was replaced by a Polish-born Soviet marshal, Konstanty Rokossowski, who on May 8, 1950, was co-opted to the political bureau of the PZPR. Many former active members of the PPR and the People's Army were arrested. In addition to Communists suspected of the "rightist-nationalist deviations," a considerable number of non-Communist political leaders and senior military men were arrested and sometimes tortured. Several political trials were staged with numerous sentences of death, which however were mainly not carried out. A trial of Gomulka and Spychalski was prepared.

The other political groupings outside of the PZPR did not play any noteworthy role in political life. On Nov. 29, 1949, the peasant parties combined into the United Peasant Party. The Christian-Democratic Labour Party was dissolved in July 1950, some of its members going into the Democratic Party. The "Pax" association, which cooperated with the three parties, comprised Catholic activists with a right-wing political past; it was sharply opposed by the Catholic Church hierarchy. Relations between the hierarchy and the government were tense and on Sept. 27, 1953, Stefan Cardinal Wyszynski (1901-), the primate of Poland, was interned. On Dec. 17, 1953, the bishops took an oath of loyalty to the Polish state.

On July 22, 1952, the *sejm* passed a new constitution. In the elections on Oct. 26, 1952, there were single lists of the National Front, with as many candidates as seats. According to the official data, 99.8% of the valid votes were cast for these lists. In accordance with the new constitution the president of the republic was replaced by the Council of State, of which Aleksander Zawadzki (1899-1964) became chairman. The new government was formed by Bierut, but on March 19, 1954, he resigned to become first secretary of the PZPR. Cyrankiewicz was again appointed premier.

Stalin's death and the new political course taken in the U.S.S.R. led to changes in Polish political life. The first modest changes came in the economic sphere. In March 1954 the 2nd congress of the PZPR adopted a resolution calling for the reduction of investment outlays in industry, for acceleration of the development of agriculture, and for the raising of the standard of living in 1954-55. Collectivization of agriculture was to be continued, but with less pressure on the peasants. Stanislaw Radkiewicz (1903-), the minister of public security, was removed from

office on Dec. 7, 1954, several high officials of that ministry were arrested on charges of using torture to force some persons to give evidence, and the ministry itself was dissolved. The slow, evolutionary process of liberalization was continued in 1955. Many political prisoners were released, but the political charges against Gomulka were not lifted. Great activity was displayed by intellectuals who demanded the acceleration and deepening of the democratization process. The turning point came after the 20th congress of the Communist Party of the Soviet Union and the famous report delivered at it on Feb. 25, 1956, by Nikita S. Khrushchev. (J. Hr.)

6. The Return of Gomulka.—The year 1956 was one of great upheaval, which some described as a successful bloodless revolution. Bierut's death (March 12) left the leadership of the PZPR deeply divided. No member of the political bureau had any real prestige. On March 20 the party's Central Committee elected Edward Ochab as its first secretary—obviously a temporary measure. Berman was dismissed from the political bureau and from his office as deputy premier on May 6.

On June 28, 1956, an event of historic significance broke down the pretense of popular support for the regime introduced by the Bierut-Berman-Minc triumvirate. Industrial workers of Poznan—in a province of traditionally law-abiding citizens—staged a general strike, and a procession of 50,000 demanded bread, freedom, free elections, and the departure of the Russians. Riots followed, a security police officer was lynched, and order was restored the following day only by the army's use of tanks. According to official reports, 53 people were killed and 200 wounded.

The plenary session of the Central Committee in July 1956 became a contest during which three trends were apparent. The Stalinists or Moscovites (so-called because they stayed in the U.S.S.R. during World War II) recommended strict censorship of the press and the curtailment of liberalization. They were opposed by the younger generation of Communist leaders who had remained in German-occupied Poland and who wanted liberalization to continue. Between these two groups were the Realists, led by Ochab and Cyrankiewicz, also supporters of change but desiring to achieve it without creating anarchy. The only man who could restore party unity and authority and count on wider support was Gomulka. All three groups agreed to his return to the political bureau, though it was clear that the Stalinists wanted him only as a figurehead. On Aug. 4 Gomulka was rehabilitated and restored as a party member. On Oct. 9 Minc, the last of the triumvirate, resigned from the political bureau and from his office of deputy premier. Agreement was reached between Ochab, Cyrankiewicz, and Gomulka as to the composition of the new political bureau.

On Oct. 19, 1956, when the party's Central Committee had assembled to elect a new political bureau, quite unexpectedly N. S. Khrushchev, V. M. Molotov, L. M. Kaganovich, and A. I. Mikoyan arrived in Warsaw. Marshal I. S. Konev, commander in chief of the armed forces of the Warsaw Treaty (signed on May 14, 1955), also arrived; Soviet divisions stationed in Silesia were moving toward the capital, allegedly on "autumn maneuvers." The meeting of the Central Committee, after co-opting Gomulka as its new member, decided that the old political bureau, with Gomulka, would discuss Polish-Soviet relations with the Soviet guests.

The consequent meeting, held in the Belweder Palace on the night of Oct. 19–20, was stormy, as the Polish leaders boldly explained to the Soviet visitors that the Polish people's democracy must be an equal and sovereign member of the Socialist camp. Meanwhile Polish workers and students, aroused by the Soviet intervention, demonstrated in protest against foreign pressure and in support of Gomulka. Khrushchev chiefly wanted to learn that the return of Gomulka to power would not mean an estrangement in Soviet-Polish relations. Convinced that such a danger was imaginary, he retreated and on Oct. 20 returned with his colleagues to Moscow.

On Oct. 21 the Central Committee elected a new nine-member political bureau. In a secret ballot, Gomulka obtained 74 votes, the maximum possible being 75. No member of the old Stalinist

group remained in the new key body of the party.

In quick succession Gomulka introduced a series of important changes. On Nov. 13, 1956, General Spychalski succeeded Rokossowski as minister of defense, and 32 Russian officers in the high command of the Polish armed forces were replaced by Poles. The powers of the security police were curtailed, and the police body itself was subjected to government control. Political prisoners were freed and many of them rehabilitated. The *sejm* ceased to be a political recording machine and a *claque*; to some extent at least it became a legislative body and an organ to control the administration. Gomulka also put an end to forced collectivization of agriculture, permitting the unsound producers' cooperatives (similar to Soviet kolkhozy) to dissolve themselves. Almost overnight, about 9,000 out of a total of 10,616 of such farms disappeared; four-fifths of the arable land remained private property of the peasants. Censorship of printed matter and theatrical performances became more liberal. Last, but not least important, Cardinal Wyszynski was released from internment and on Oct. 28, 1956, returned to Warsaw. Five bishops and dozens of priests were released from confinement; and by the agreement of Dec. 8, freedom of worship was restored and appointment of bishops according to canon law guaranteed.

On Jan. 20, 1957, a new *sejm* was elected. According to the new electoral law there was only one list of candidates in every one of the 116 constituencies, but there were 723 candidates for 459 seats. The elections of April 16, 1961, and of May 30, 1965, were held according to the same principle. In 1961 and 1965, however, there were 80 constituencies and, respectively, 616 and 670 candidates for 460 seats: in both years, 255 Communists, 117 Peasants, 39 Democrats, and 49 Independents (including, in 1965, 13 Catholic leaders) were elected.

In March 1959 the third congress of the PZPR was held in Warsaw. The party numbered then 1,072,932 full members and candidates as compared with 1,296,938 at the time of its second congress in March 1952. At the time of its fourth congress (June 1964) the party's membership had risen to 1,614,273.

By 1966 the fundamental gains of the upheaval of 1956 were being upheld; but censorship of the printed word became stricter, though exercised mainly on discussion of Marxist themes or of Poland's relations with the U.S.S.R. Serious friction flared up between church and state in December 1965, when the government learned from the West German press that the Polish and German hierarchies had exchanged highly political letters. Having proclaimed the Oder-Neisse frontier as final, the Polish bishops recognized this frontier as being, for the Germans, "a bitter fruit of the last war of mass annihilation"; "We forgive and ask for forgiveness," they concluded. The Polish government protested against this exchange, first because it had taken place without its knowledge, second because the German bishops, in their reply, had countered by endorsing the "revisionist" claim of a "right to the homeland." The ensuing polemics between Gomulka and Cardinal Wyszynski marred the millenary celebrations, in 1966, of Poland's conversion to Christianity. Gomulka considered himself the responsible leader of the nation, while the cardinal saw himself as its true spiritual pastor; both were men reluctant to compromise.

7. Foreign Policy from October 1956.—In November 1956 Gomulka and Cyrankiewicz visited Moscow. There they agreed with Khrushchev and his colleagues that the Polish-Soviet alliance was a guarantee of security for both sides; secured confirmation of "the inviolability of the Polish-German frontier on the Oder-Neisse line"; and acknowledged that the temporary presence of Soviet Army units on Polish territory was still "desirable." As certain financial problems between Poland and the U.S.S.R. had been unadjusted for years, the two governments agreed to consider as canceled, as from Nov. 1, 1956, Poland's indebtedness for the credits granted by the U.S.S.R. between 1949 and 1956—credits amounting to 2,300,000,000 rubles (\$575,000,000). From 1945 to November 1953 Poland had delivered to the U.S.S.R. about 50,000 tons of coal at a nominal price of \$1.25 per ton. From 1954, world market prices without exception were applied to Polish-Soviet trade.

On Feb. 14, 1958, Adam Rapacki, the foreign minister, proposed that in a zone comprising Poland, Czechoslovakia, and the two German republics no nuclear weapons should be manufactured or stockpiled, that all equipment and installation designed for servicing of such weapons should be banned, and that the use of these weapons against the four states of the zone should be prohibited. On Nov. 4 Rapacki presented a revised version of his plan, dividing it into two stages: in the first stage, all the parties should agree that no nuclear weapons should be manufactured in the zone and that no nuclear weapons should be supplied to armies in the area that did not already possess them; in the second stage, a ban on nuclear weapons should be tied up with a reduction of conventional forces in the zone. On March 28, 1962, Rapacki submitted to the 18-nation disarmament conference in Geneva a third version of his plan, introducing a section dealing with international control and inspection within the zone. On Feb. 29, 1964, a Polish memorandum on the freezing of nuclear armaments in central Europe was delivered to the governments of the area and to those controlling military contingents in it. This proposal was known as the Gomulka Plan.

Leonid Brezhnev and Aleksei Kosygin, the new Soviet leaders, visited Warsaw in April 1965, and on April 8 a new Polish-Soviet 20-year treaty of mutual assistance was signed.

By 1966 there were still no diplomatic relations between the Federal Republic of Germany and Poland. One reason was the so-called Hallstein Doctrine, according to which no diplomatic relations could exist between the Federal Republic of Germany and any other state (the U.S.S.R. excepted) which recognized the German Democratic Republic. Another reason was the Warsaw government's demand that, as a precondition to the establishment of diplomatic relations, the Bonn government should accept the existing Polish-German frontier.

IV. POPULATION

The first census (1921) after the restoration of the Polish state revealed a total population of 27,176,717; the second (1931) a total of 32,107,252, and an official estimate for September 1939 put the total at 35,339,000 (excluding the Cieszyn disputed territory). Between World Wars I and II Poland was not a homogeneous national state. At the 1931 census just under one-third of the population gave their mother tongue as other than Polish.

Poland: Administrative Units

Province (województwo)	Area		Population (Dec. 6, 1960, census)
	(sq.km.)	(sq.mi.)	
Warsaw (city)	446	172	1,139,189
Warsaw	29,370	11,340	2,314,930
Białystok	23,146	8,937	1,090,231
Bydgoszcz	20,798	8,030	1,708,298
Cracow (city)	230	89	481,296
Cracow	15,350	5,927	1,990,359

Wroclaw (city)	225	87	430,522
Wroclaw	18,827	7,269	1,806,310
Zielona Gora	14,514	5,604	782,332
Total	311,730	120,359	29,775,508*

*Source: *Rocznik Statystyczny 1964*; 369,779 people not included in the above mentioned administrative units.

No part of Europe was more profoundly affected by the great displacements of population which occurred in and immediately after World War II and for a few years afterward. Polish citizens were deported by both occupying powers during the German-Soviet partition and by the Germans over the whole of Poland after June 1941. Of Poland's 3,351,000 Jews (1939 est.) the great majority were murdered at Oswiecim (Auschwitz) and other extermination camps, and only about 90,000 remained in Poland after 1945; most of these had been hidden by Poles at risk of death.

The territories annexed by the U.S.S.R. had in 1939 a population of 10,864,000; by June 1949, 1,503,800 persons of Polish nationality had been transferred from Soviet territory to the new Poland, while 518,200 Ukrainians, Belorussians, and Lithuanians had been moved from Poland to their respective Soviet republics. A smaller repatriation of Poles from the U.S.S.R. took place between 1955 and 1959 when about 275,000 persons returned to Poland.

According to the German census of May 17, 1939, the population of the then German lands east of the Oder-Neisse line incorporated into Poland in 1945 amounted to 8,372,700. To this total must be added the German population of the Free City of Danzig (392,000 in 1939) and the German minority in the pre-1939 frontiers of Poland (741,000), but there must be subtracted 1,011,700 Poles living between the Versailles and Potsdam frontiers of Poland. Theoretically, the total number of Germans living within the frontiers of 1945 Poland was about 8,494,000. In fact, toward the end of 1944, they were more than 10,000,000, because their number was increased by the repatriation of the Germans from the Baltic states, Bukovina, and Bessarabia (353,000); by the German personnel of the civil and military administration sent there after occupation (470,000); and by 725,000 evacuees from central and western German cities bombed by the British and U.S. Air Forces. The majority of those Germans fled westward before the advancing Soviet armies and in May 1945 only about 4,400,000 remained.

According to the census of February 1946 the population of Poland within its new frontiers was 23,929,757, including 2,288,300 Germans. By the end of 1948 a further 2,170,866 Germans had been repatriated from Poland to the Soviet, British, and U.S. zones of occupied Germany, while 2,266,000 Polish forced labourers, prisoners of war, and demobilized soldiers returned to Poland from Germany and from western Europe. The Polish census of December 1950 revealed a total population of 25,008,179; that of December 1960 a population of 29,775,508. It was overwhelmingly Polish, although small national minorities, which enjoyed cultural autonomy, were: Ukrainians 180,000; Belorussians 165,000; Jews 31,000; Slovaks 21,000; Russians 19,000; Lithuanians 10,000; Germans 3,000; Czechs 2,000; others (gypsies, Greeks, etc.) 22,000.

The natural increase in the years 1950-56 was on the average 19.1 per thousand; between 1957-60 it fell from 18.1 to 14.9 per thousand. In 1950 the female population constituted 52.3% of the total, but in 1960 this proportion fell to 51.6%. The density of population in 1960 was 247 per sq.mi. (236 in 1939), and approximately 49% of the people were classified as urban (27% in 1931). This increase in urban population does not reflect a steady growth of towns. Many towns, particularly Baltic and Silesian, suffered damage and population loss during World War II but most of them had regained their former size by the 1960s. Warsaw, for example, had a population of 937,000 in 1921, 1,289,000 in 1939, 479,000 in 1946 and 1,139,189 in 1960.

Poles abroad are divided into two categories: the autochthonous Poles inhabiting alien territory contiguous with the political frontiers of Poland, and the emigrants or refugees. Between the two World Wars the largest groups of autochthonous Poles were in eastern Germany, their number being estimated in 1939 at more than 1,000,000. Nearly 1,220,000 lived in the Ukraine, Belorussia, Lithuania, Latvia, Rumania, and Czechoslovakia. The situation changed radically after World War II. According to the Soviet census of January 1959 there were 1,380,000 Poles in the U.S.S.R., mainly in the Ukraine, in Belorussia, and in Lithuania. Poles in the German Democratic Republic numbered about 50,000 and in the Federal Republic of Germany (mostly in the Ruhr basin) about 132,000. Their number in Czechoslovakia (1961 census) was 84,500.

The largest number of emigrants from mid-19th century to 1939 settled in the United States. In the early 1960s, 6,372,000 Americans were estimated to be of Polish descent; and an additional 178,000 Poles had entered the U.S. between 1941-62 as displaced persons, refugees, or immigrants. The 1940 census revealed that there were 2,416,320 persons in the United States whose mother

tongue was Polish—the largest non-English-speaking group after the German and Italian speakers. According to the 1960 census 747,750 of the U.S. population were born in Poland. These loyal U.S. citizens were proud of their origin and maintained a strong interest in Polish culture through their own Polish-speaking educational and religious organizations. In the 1960s nearly 60 Polish periodicals appeared in the United States, including daily and weekly newspapers. Other groups of Polish emigrants in the 1960s included: 400,000 in Brazil, 260,000 in Canada, 120,000 in Argentina, and 72,000 in Australia. The largest group of emigrant Poles in Europe after World War I went to France, settling for the most part in the northern and eastern mining areas. In the early 1960s they numbered about 750,000, mostly French citizens. More than a dozen Polish journals were published.

A significant change brought about by the political consequences of World War II was the establishment of a Polish colony in Great Britain. The majority of the 140,000 Poles in that country, including 36,200 naturalized British (1962), was constituted by former servicemen and their families. Many cultural, social, professional, and trade organizations were established. There were in the early 1960s more than 30 Polish periodicals published in Great Britain.

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—The first constitution after the restoration of the Polish state, promulgated in March 1921, was modeled on the French system. The first *sejm*, or Chamber of Deputies, elected under a system of proportional representation, contained 16 parliamentary groups, four of which represented national minorities. A new constitution promulgated in April 1935 increased the power of the president of the republic, but the *sejm* fixed the budget and had the right to demand the resignation of the government. Under Article 24, in time of war the president had the right to appoint his successor.

After World War II the Warsaw provisional government promulgated (in February 1947) a temporary constitutional act which was democratic but never became effective, and a new constitution was passed by the *sejm* in July 1952. Under this the supreme organ of state authority was the Council of State (*rada stanu*), composed of a chairman, three deputy chairmen, a secretary, and nine members. The supreme organ of state administration was the Council of Ministers appointed by and responsible to the *sejm*, or to the Council of State if the *sejm* were not in session. The electoral law adopted by the *sejm* in August 1952 accorded the franchise to all citizens of 18 years, including members of the armed forces; citizens of 21 years were eligible for election. There was one deputy for every 60,000 inhabitants, but in every constituency there could be only one list of candidates equal in number to the deputies fixed for the constituency. The candidates were formally nominated by the National Front, which grouped the three existing political parties, the Polish United Workers (Communist), the United Peasant, and the Democratic. In October 1956 the electoral law was slightly improved so that in January 1957 the electors could select their 459 deputies from 723 candidates. At the election of April 1961 there were 616, and at that of May 1965 there were 670, candidates for 460 seats. The Communists always managed to obtain an absolute majority in the *sejm*.

2. Local Government.—From June 1950 the number of provinces (*województwa*) was increased to 17 by the creation of three new provinces in the western territories. The five largest cities (Warsaw, Poznan, Lodz, Wroclaw, and Cracow) formed separate administrative units (*see* Table). Each province is divided into a number of districts (*powiaty*).

3. Taxation.—In Poland, as in every other people's democracy, direct taxation is small and amounts to about 7% of the national budget revenue; the main direct tax is that on wages. Indirect taxation is high and is included in the price of goods produced by the socialized economy and supplied to the population in state-owned stores and shops.

4. Living Conditions.—**Employment.**—In prewar Poland, according to the 1931 census, there were 4,881,500 persons employed, including 3,452,600 outside agriculture and forestry. In postwar

Poland, in a different area and with a smaller population, the total employment rose between 1949 and 1963 from 4,025,800 to 8,050,800. While in 1931 the number of employed in agriculture and forestry amounted to 1,428,900, in 1963 it was only 605,700, but the number of persons employed in industry rose during the same period from 1,781,500 to 3,370,300. Postwar figures for industry comprise only persons employed in state enterprises. In addition, in 1961, there were 23,880 persons employed in small private industrial enterprises and 167,028 self-employed artisans.

Housing.—In prewar Poland most houses were built privately and up-to-date housing was accessible only to those who could afford to pay high rents. After 1945 the great bulk of housing construction was taken over by the state. The share of rent (plus utilities rates) in the family budgets of working people dropped substantially as compared to the prewar period. In 1960 there were in Poland 3,849,500 dwelling houses with 17,242,900 rooms; these totals included 2,828,200 houses in the countryside with 8,382,500 rooms; the average number of persons per room amounted to 1.53 in towns and to 1.8 in the countryside.

5. Social Welfare.—Medical care was provided in the 1960s free of charge to all workers and their families, that is to about 60% of the population. Connected with this was the expansion of hospital facilities and of the medical and nursing staff. Though there was a substantial increase in all fields, much was still to be done. Between 1938 and 1963 the number of doctors rose from 12,917 to 35,171, that of dentists from 3,686 to 10,593.

All workers have the right to paid holidays. After one year of employment white-collar workers receive a 30-day holiday; physical workers are entitled to 12 days after one year, 16 days after three years, and 30 days after ten years of employment. The Workers' Holiday Fund, functioning under the supervision of the Central Council of Trade Unions, helps the workers to arrange their vacations. The fund has more than 1,500 rest homes and about 500,000 persons benefit yearly from these holidays.

6. Justice.—Administration of justice is assured by the Supreme Court, 19 provincial courts, and 331 district courts. According to the constitution judges are independent.

7. Education.—The policy of the post-1945 Polish government was the gradual replacement of the old system of state, municipal, and private establishments by a uniform, secular state educational system at every level. All private and independent institutions had by 1952 been closed or subjected to governmental supervision. Primary education is compulsory for all children of 7 to 15 years of age. The state created no obstacles for parents who wished their children to be taught the principles of religion, but religious teaching should be given out of school. There are various types of secondary schools, such as the four-year general secondary school, the three-year vocational school, and the five-year technical school. Institutions of higher education include universities, colleges of engineering, and medical academies. Education at all schools and higher institutions is free, but admission to a secondary or high school requires the passing of preliminary examinations. In post-1945 Poland there was a considerable increase in the number of schools, pupils, and teachers. Between 1937 and 1963 institutions of higher education increased from 32 to 74 and students from 49,534 to 212,558.

The University of Cracow is one of the oldest in Europe (*see* CRACOW), but the loss of the eastern territories deprived Poland of its old universities of Wilno (Vilnius), founded by Stephen Báthory in 1578, and of Lvov, founded by John Casimir in 1661. There were also in pre-1939 Poland state universities in Warsaw and in Poznan, and a Catholic university in Lublin. Four new state universities were founded after 1945, in Wroclaw, Torun, Lodz, and Lublin. The Catholic university in Lublin survived, the only institution of its kind in a Communist country. Before 1939 there were two colleges of engineering (Warsaw and Lvov); in the 1960s there were ten.

In January 1949 an act to eliminate illiteracy was passed. As a mass phenomenon illiteracy ceased to exist in Poland. Various opportunities were provided for adults to pursue their education and attain higher standards of skill.

8. Defense.—Between the armed forces of pre-1939 Poland and

those established after 1945 there was no continuity; personnel, organization, training, and equipment were completely changed. The Polish Army suffered catastrophically from the German and Soviet invasions, although certain Naval, Army, and Air Force units escaped abroad and made an important contribution to the Allied war effort from the Polish headquarters in Britain.

Including the forces of the interior (frontier guards and security troops), the Polish Armed Forces were estimated in the early 1960s at 300,000. There were three military areas (Warsaw, Bydgoszcz, and Wrocław) comprising 14 motorized and armoured divisions of the land forces. The Air Force was believed to amount to 12 air divisions (about 1,000 fighters and tactical bombers) and there was a separate antiaircraft command. The Polish Navy had three destroyers, seven submarines, and a number of minesweepers and auxiliary craft (190 ships in all).

Military service was universal and compulsory between the ages of 20 and 50. According to the law of Jan. 30, 1959, active service was two years for the Army, three years for the Air Force and the Navy, two years for antiaircraft units, and 27 months for the forces of the interior. In March 1963 the *sejm* lowered the call up age from 20 to 19, and cut the period of service in the Army from 24 to 18 months, but lengthened it in a number of specialized units, which use modern weapons and equipment. (K. Sm.)

VI. THE ECONOMY

The economic development of Poland following its emergence as a modern independent state after World War I was greatly influenced by its vulnerable position in a continent riven with deep national and political antagonisms. Economic viability in the interwar years was complicated by the widely contrasted social conditions in the areas inherited from Germany, Russia, and Austria, while the new, sinuous frontiers caused severe disruption of former trading patterns and induced great economic and political tensions in areas such as Upper Silesia and the so-called Polish Corridor. Political dismemberment and massive destruction of human and physical resources during World War II (two-fifths of the total national wealth and one-fifth of the population were destroyed) bequeathed serious problems of postwar reconstruction and resettlement to a country which was territorially displaced westward while being ideologically incorporated in the Communist bloc. The transformation of economic conditions which subsequently occurred owed much to the acquisition of new resources and to Communist policies such as emphasis on heavy industrialization and on the attempted collectivization of peasant agriculture. Important modifications of economic planning, particularly in agriculture, occurred after the political changes of October 1956.

A. PRODUCTION

1. Agriculture.—Between World Wars I and II Poland was

a predominantly agricultural country. Agricultural land accounted for two-thirds of the total area and arable land alone nearly half. After World War I large estates of 123 ac. (50 ha.) and more accounted for about one-quarter of the total area (those exceeding 1,235 ac. [500 ha.], one-fifth), the remainder being divided into smaller estates, of which nearly one-third were less than 5 ac. (2 ha.) and a similar proportion between 5 and 12 ac. (2 and 5 ha.). In 1920 a land reform act was passed to encourage redistribution of land, with compensation, under state control. By the end of 1938 one-quarter of the land belonging to the large estates had been distributed and the amount of land which had by then passed from the large estates to the small farmers and landless peasants equaled the area of all the arable land in England and Wales. In this interwar period more than 700,000 people received land in this way, yet Poland continued to suffer from rural overpopulation, particularly in the south and east.

Although Poland was one-fifth smaller after 1945 than before 1939, arable land was reduced proportionately less, for it occupied a smaller share in the east than in the west. Thus agricultural land still accounted for about two-thirds of the total area, but the share of arable land alone rose to nearly three-fifths. By its decree of Sept. 6, 1944, the Polish Committee of National Liberation expropriated without compensation all private holdings exceeding 124 ac. (50 ha.), except church land, although that too was confiscated in the reform of March 20, 1950. In all, in January 1949, in the territories which were part of Poland before 1939, more than 2,965,200 ac. (1,200,000 ha.) of arable land were received by about 400,000 peasants, while in the recovered territories in the west 9,884,000 ac. (4,000,000 ha.) were shared out and about 480,000 new small holdings were created.

The land reform increased, in number and proportion, both the very small farms of under 5 ac. (2 ha.), which were economically unsound, and the larger holdings between 25 and 124 ac. (10 and 50 ha.) owned by the richer peasants. The economic and political problems thereby posed to the government, which was anxious to rationalize agriculture as a means of releasing labour for the industrialization program, led to efforts to collectivize peasant holdings in producers' cooperatives. By June 1956 there were nearly 10,000 cooperatives occupying one-tenth of the agricultural land. Collectivization proceeded fairly rapidly in most of the recovered territories, but in the older areas of Polish peasant farming the policy met with stronger resistance (less than 2% of Kielce and Cracow *województwa* were collectivized). Another one-eighth of the agricultural area was administered by about 6,500 state farms, established predominantly in the recovered territories on the basis of the large prewar German estates. Following the political upheaval of October 1956 the unpopular cooperative farms were largely disbanded; by the early 1960s only about 1,800 survived, accounting for little more than 1% of the agricultural land.

HENRYK HERMANOWICZ, KRAKOW

FARMLANDS GIVE WAY TO STEEL MILLS AT NOWA HUTA, A SUBURB OF CRACOW

The state farms, in contrast, were largely maintained, although there was a small reduction to about 6,000 by the early 1960s.

In 1959 approval was given to a seven-year plan for Polish agriculture which involved a gross increase in output of 30% between 1958 and 1965 and stressed the need for mechanization and for a reduction in the number of horses. A new form of cooperation was defined in terms of "agricultural circles" entitled to financial help, particularly for mechanization, from an agricultural development fund. By the early 1960s there were about 25,000 such circles, with a membership (including that of the rural housewives' associations) approaching 1,000,000, and utilizing 190,267 ac. (77,000 ha.) of agricultural land.

Crops.—Climate and soil combine to give Poland a mixed type of farming. The main crops are grains (rye, oats, wheat, and barley, in that order of importance), potatoes, sugar beet, and fodder crops. Rye and potatoes are more characteristic of the poorer sandy soils of the glaciated regions, wheat and sugar beet of the more fertile brown soils of southern Poland. Hops and tobacco are located on favourable soils in the centre and south, and fruit is grown in most districts.

Livestock.—Dairy and poultry farming and the raising of pigs are found in most areas of the country. During the second half of the 1940s there was a striking recovery in the number of livestock, and by the early 1960s there were nearly the same number of cattle as in 1938 (for the post-1945 territory), while the number of pigs and sheep had increased by about 40 and 80% respectively. The drop of about one-sixth in the number of horses reflected the increasing degree of mechanization.

Postwar Trends.—The 1950s witnessed a growing concentration on foodstuffs of value to the export market, such as sugar, poultry products, bacon, and ham. By the early 1960s sugar production, for example, was double the prewar figure. The demands of the export drive and the victualing of the considerable armed forces imposed heavy demands on agriculture. Moreover, production was hindered by changes in the agrarian system, lack of incentives for farmers, and locally by the diversion of agricultural labour into industrial employment. At the beginning of the 1930s the agricultural population had been three-fifths of the total, but 30 years later the proportion was less than two-fifths. Internal food shortages became apparent in 1948 and have been intermittently experienced since. From 1953 Poland had to import large quantities of grain, whereas before World War II there had been both grain and potato surpluses for export.

2. Forestry.—Nearly one-quarter of Poland was afforested by the mid-1960s, compared to 21% at the end of the war. The proportion of the forest area covered by the state forest administration rose to over 80%, compared to only 37% in prewar years. About one-sixth of the forests are still owned by small peasant

proprietors. The growth of industrial demand for timber, for example in construction and chemicals, encouraged a major afforestation program on poorer land, which was planned to increase the total area under forests to 27% of the country by 1975. Most of the forested regions are on the sandy, lighter soils of the lowlands, notably in Zielona Gora and Olsztyn *województwa*, and in the upland and mountainous areas of the southern margins, where afforestation is further encouraged by flood prevention requirements.

3. Fishing.—The growing role of Poland as a maritime power since 1945 is reflected in the increasing importance of fishing, in terms both of catch and of building vessels. By the mid-1960s Poland had become a major exporter of fishing vessels, and was second only to Japan in their construction. In the early 1960s most Polish trawlers were operating in the North Sea and North Atlantic (mainly off Norway), but falling and variable yields led to intensive search for new and more distant fishing grounds for the deep-sea vessels.

4. Industry.—After World War II a short-term (1947–49) recovery plan was drawn up to make good the war losses and to adjust the economy to the conditions presented by major frontier changes. The total capital expenditure envisaged was nearly \$2,000,000,000, of which two-fifths was for industry and one-quarter for transport. Rapid industrialization, however, was hindered by the inability of the U.S.S.R. to spare capital goods and by the growing reluctance of the Western industrialized countries to supply capital (and potentially strategic) goods to Communist countries. Supplies valued at \$471,000,000 were provided by the UN Relief and Rehabilitation Administration, and \$42,000,000 of Polish gold and other assets in U.S. and British banks were released in 1946–47. However, following Poland's rejection, at the behest of the U.S.S.R., of the European Recovery Program, the six-year industrialization plan (1950–55) was compelled to rely for its capital largely on internal or other Communist sources. This imposed severe strains upon the economy, and, with the worsening of East-West relations forcing further investment funds into heavy strategic industries at the expense of consumer goods and housing, general living standards remained low or even deteriorated. In 1950 the industrial targets of the plan were revised upward drastically, the proposed increase in industrial output for the period being put at 158% instead of the 95% originally envisaged.

Although the ambitious targets of the six-year plan were not always realized, substantial progress was recorded. Over a rather longer period, 1949–57, total industrial output increased about three times, with an increase in industrial employment of only two-thirds. In 1956 a new five-year plan was introduced, envisaging a great expansion of the chemical industry, the doubling of production of machinery and metal products, and a further increase of one-third in nonagricultural employment in the socialized

economy. In 1957 work was begun on a long-term (1961-75) plan to serve as a general framework for the more detailed five-year plans, and in 1959 it was announced that during these 15 years industry's contribution to the national income would rise from 46 to 57%.

The targets set in the 1956-60 plan were generally achieved, with a total increase in gross industrial production of 58%. Iron ore production rose by 32%, while the new copper field near Glogow provided an increase of over 70% on the 1955 output of copper ore. The production of sulfur, calcinated soda, insecticides, and pharmaceuticals more than doubled. The growth of employment during the same period was relatively small (11%), indicating substantial increases in industrial productivity.

The main objective of the 1961-65 plan was to encourage such increase in productivity by modernization and technological advances. The gross increase in industrial production was to be 52% (compared with only 22% in agriculture), with particularly high rates of growth planned for electricity, chemicals, iron and steel, and building materials. About 600 new industrial plants were included in the investment program, and by 1964 industrial employment had risen by about 380,000 (12% above 1960) to reach 3,390,000.

Throughout the two postwar decades the implementation of industrial plans was aided by the acquisition of major economic resources and by fresh discoveries of mineral deposits. Such resources included, in particular, coal and copper in Silesia. This region, moreover, together with the ports of Danzig, or Gdansk, and Szczecin (Stettin), was already highly industrialized by pre-war Polish standards and became the focus of major new investments.

Coal Mining.—Postwar boundary changes led to the inclusion of the whole of the Upper Silesian coalfield within Polish territory, while further gains included the smaller but valuable coking coal deposits near Walbrzych and the lignite fields near Sagan (Zagan) and Zgorzelec. By 1955 production of hard coal had reached 95,000,000 tons a year, but the target figures of the 1956-60 plan were not quite attained because of a decrease in volunteer working on public holidays. A slow growth rate of 11% over the whole period was partly compensated by an increase of more than 50% in lignite production to a total of over 9,000,000 tons in 1960. This disproportion was maintained in the 1961-65 plan, with a 10% increase for hard coal strikingly exceeded by an increase of nearly 200% for brown coal. Lignite was playing a more important, but still relatively minor, role (5% in 1960) in the generation of electricity, and it was intended that this function should figure prominently during the period 1965-80 when long-term plans envisaged a total brown coal output of about 110,000,000 tons. The main lignite fields occur near Konin and Leczyca in central Poland, and near Turow in the southwest.

Metal Industries.—Communist planning has placed great emphasis on the growth of the heavy-metal industries, notably iron and steel, and an early spectacular example of this priority occurred during the six-year plan with the construction of the Nowa Huta steelworks (capacity 3,500,000 tons annually) immediately east of the historic capital of Cracow. Steel production was also expanded at Czestochowa and at centres such as Zabrze in the Upper Silesian industrial district (Gornoslaski Okreg Przemyslowy, or G.O.P.). Between 1956 and 1960 steel production increased by over 50% to a total output of 6,700,000 tons, and the following five-year plan forecast a further increase of about 40%. During this plan period capital outlays in the metallurgical industry as a whole amounted to 13.5% of total investment in industry. Other major products include electrolytic copper and zinc, whose production in the early 1960s yielded 24,000 and 180,000 tons respectively. The expansion of the metal industries has been hindered by the paucity of good native iron ore resources, and despite rapid expansion at such centres as Leczyca, Poland still relies heavily on imports from the Soviet Union and Sweden.

Power.—The expansion of electric-power production has been rapid since the war, and from less than 10,000,000,000 kw-hr. in 1950 there was an increase to 29,300,000,000 kw-hr. in 1960, and an even faster annual rate of increase during the early 1960s.

Many new power stations were installed, notably the Turoszow plant based on lignite in the extreme southwest of the country. Coal continued to provide the overwhelming bulk of Poland's power requirements, but there was a growth too in the production of oil and natural gas with the discovery of new oil deposits in the Carpathian foothills and of rich natural gas fields in the Lubaczow region. The makeup of the country renders unlikely any major contribution from hydroelectricity.

Chemicals.—Since 1955 this has been one of the conspicuous growth industries of Poland. The traditional centres of the industry were in the south, related to the fossil-fuel deposits in particular, but new centres have appeared at Plock and Pulawy on the Vistula, whose primary materials were to be supplied by pipeline from the Soviet Union. The Plock oil refinery receives oil from the Volga field (the Romashkin area), and the Pulawy nitrogen combine was to use natural gas from the Soviet fields north of the Carpathians. The Pulawy combine was one of the major industrial investments of the 1960s and was particularly intended to improve the productivity of Polish agriculture. The Plock refinery was one of several consequences of the completion of the oil pipeline in late 1963, which would help satisfy a national oil consumption expected to rise from 4,000,000 tons in 1963 to 9,000,000 tons in 1970. Other major chemical plants, based also on natural gas, were to be expanded during the 1960s at Oswiecim, Tarnow, and Blachownia Slaska. At Tarnobrzeg the intensive development of sulfur mining to a yield of 400,000 tons in 1965 permitted an increase of 94% in the production of sulfuric acid between 1961 and 1965. Particular emphasis was also placed on the production of plastics, rubber, man-made fibres, and detergents.

Building.—The devastation caused by World War II, notably in large cities such as Warsaw, Szczecin, Danzig, and Wroclaw, presented a major challenge to the building and construction industries. The priority given to heavy industrialization in the post-war plans, together with the rapid influx of population into the towns, led to generally low-housing standards persisting until the late 1950s. Between 1956 and 1960, however, a slow improvement was felt, with the building of 618,000 flats, or an increase of 80% over the comparable period at the beginning of the decade. The deterioration of living standards in the small country towns, which had been marked in the early 1950s, was also arrested, and some encouragement was given to private house building. Shortages of building materials continued to be felt, despite the expansion of such materials as cement near Opole and a growing emphasis on prefabrication. A notable feature of the late-1950s and early-1960s was a lively architectural experimentation in marked contrast to the postwar style of "socialist realism."

B. TRADE AND FINANCE

1. Foreign Trade.—The transition from a mixed to a Communist economy was paralleled by important changes in Poland's economic relations. Before World War II its main trading partners were Western European countries and the United States, but after the war there was a very pronounced shift of trade toward other Communist countries. Increasing reliance upon the U.S.S.R. during the three-year plan, and even more so during the six-year plan, led to that country's playing a commanding role in Polish trade turnover in the early 1950s. Toward the end of the six-year plan the Communist bloc handled seven-tenths of total Polish trade, with the U.S.S.R. itself responsible for about half of Poland's trade with all the Communist states. However, after October 1956 the Polish government, concerned about improving material standards of living, began to forge fresh trade links with the West. A three-year (1957-59) trade agreement was signed with Great Britain and by the early 1960s trade with that country had increased by one-third in value compared with 1956. Britain remained in fourth position among Poland's trading partners, after the Soviet Union, the German Democratic Republic, and Czechoslovakia, with the Federal Republic of Germany fifth. Sixth position was occupied by the United States, which had quadrupled the value of its trade with Poland compared with 1956. There was also a rapid growth of transactions with underdeveloped countries. Nevertheless, the increased attention paid by the Council

for Mutual Economic Assistance (Comecon) during the early 1960s to coordinating national economic plans guaranteed a sustained growth in Polish trade with the countries of the Soviet bloc.

In 1963 two-thirds of Polish imports were derived from the Soviet bloc, which in turn absorbed 64% of Polish exports, and with the growing importance of such raw materials as Soviet oil and iron ore in Polish industrialization, this pattern of trading emphasis continued during the 1960s. Such a consolidation of links with the Communist countries was partly because of developments such as the Common Market and European Free Trade Association which implied a threat of west European trade discrimination against Poland. In 1964, however, Poland became a member of the GATT (General Agreement on Tariffs and Trade) Trade Negotiations Committee in preparation for the "Kennedy round" of international tariff negotiations.

Another transformation of Polish commercial relations in the postwar period sprang from the structural changes effected in the economy. Before 1939 Polish exports consisted predominantly of agricultural products and raw materials such as coal and timber. In the late 1940s postwar disorganization of agriculture was partly responsible for a greater dependence on coal exports, though these exports declined rapidly after 1956. The replacement of livestock losses resulted in a steady increase in the export of meat products during the 1950s, but the decade was more notable for the growth in industrial exports. The shipbuilding industry began to play an increasing role, and by the early 1960s the sale of machines and fully-equipped industrial plants amounted to more than one-quarter of the total value of exports. Another important export was electric power, principally to the German Democratic Republic and Czechoslovakia. Changes in imports also reflected the development of industrialization. Iron ore imports, mainly from Krivoi Rog, U.S.S.R., increased more than fourfold between 1946 and the early 1960s, and in 1963 work was completed on a pipeline to bring Soviet oil from the Volga-Urals field.

2. Banking and Currency.—The Narodowy Bank Polski was created as a state issue bank by a decree of Jan. 15, 1945, and a uniform currency for the whole country was introduced. In 1948 a major reform produced three state banks, the Narodowy (or National) Bank, the Investment Bank, and the Agricultural Bank. These banks handle exclusively the credit requirements of socialized enterprises, and thereby act in a controlling capacity within the planning mechanism. The bulk of credit and clearing operations is handled by the National Bank, while 75% of the national financial resources are kept on account with the National Bank. Its role was further defined in a law of December 1958, and in 1960 a further law defined the legal status of the other banks. The Agricultural Bank, for example, finances and controls the management and investments of state farms, cooperative farms, and state forestry enterprises. Another state bank to be set up was the Powszechna Kasa Oszczednosci (P.K.O.) which handles the savings of the general public. The monetary unit is the zloty, with a foreign trade exchange rate of 4 zl. to U.S. \$1, or 11.20 zl. to £1 sterling, and a tourist rate of 24 zl. to U.S. \$1, 67.20 zl. to £1.

3. National Finance.—From 1950 Poland had a comprehensive Soviet-type budget including not only all government revenues and expenditures but also those of the whole nationalized economy. After 1952 expenditure

on the national economy accounted for more than half the total budget.

In 1948 and 1950 the U.S.S.R. granted credits totaling 2,200,000,000 rubles, to be made available during 1950–58 in the form of raw materials, machinery, and equipment. These credits supplemented the 185,000,000,000 zlotys to be raised from the Polish people themselves to finance the six-year plan.

German reparations were also expected to assist the industrialization of Poland. In 1945 the U.S.S.R. undertook to settle reparations to Poland by the allocation of 15% of all reparations received by the Soviet Union from Germany. In 1950, however, when the Soviet government estimated that the German Democratic Republic had paid \$3,658,000,000 (Western calculations put the figure much higher), it announced, in agreement with the Polish government, the reduction of the remaining demands by half to \$3,171,000,000. In 1953 both countries renounced further payments. The amount of the Polish share was not published.

In November 1956 the Soviet government agreed to consider as settled Poland's indebtedness for the credits already granted, thus indirectly recognizing the Polish claim that, by delivering to the Soviet Union during 1946–53 about 50,000,000 tons of coal at a nominal price of \$1.25 a ton, Poland had lost about \$740,000,000. In addition, the Soviet government agreed to grant Poland a five-year loan of 400,000,000 rubles for grain purchases and a new long-term credit of 700,000,000 rubles to purchase other Soviet products during 1958–60.

C. TRANSPORT AND COMMUNICATIONS

1. General.—The restored Poland inherited in 1918 three differing systems of communications, of which the Prussian was most highly developed, the Russian least so. The damage resulting from World War I and the Polish-Soviet War was very great. Roads were singularly ill-provided, a disadvantage from which the country was still to suffer despite continuous road building between 1921 and 1939.

The shift of frontiers in 1945 enriched the system of communications by bringing in the industrial areas of German Silesia and their outlet through the Oder Valley, a region well supplied with railways, canals, rivers, and roads. War damage was, however, higher than in World War I, and the period 1945–50 was occupied mainly with the work of reconstruction and the improvement of existing facilities. Destruction was estimated at two-

C.A.F., WARSAW

FREIGHTERS AND HARBOUR CRAFT AT GDYNIA, BALTIC PORT AND NAVAL BASE WHICH, WITH DANZIG, IS THE PRINCIPAL SHIPPING CENTRE OF POLAND

fifths of main railway tracks and locomotives, more than two-thirds of large railway bridges, almost all the freight cars, nine-tenths of passenger cars, all the motor trucks, nearly one-third of road surfaces and four-fifths of boats and barges on inland waterways. Among the more spectacular achievements after 1945 were the rebuilding of an east-west thoroughfare through Warsaw and the electrification of the two trunk lines: the Warsaw-Gliwice line (completed in 1957) and Warsaw-Poznan line (1964). The Gliwice-Wroclaw-Poznan line was also being electrified. By the mid-1960s of a total standard-gauge railway length of more than 14,292 mi. (23,000 km.) more than 932 mi. (1,500 km.) were electrified. On the roads more than 183,000 passenger cars and 155,000 trucks were in use.

Poland's merchant marine made a phenomenal increase, its total tonnage, approaching 1,000,000 tons gross (ships over 100 tons), being about ten times the tonnage before World War II. Foreign trade through the main ports (Danzig, Gdynia, and Szczecin) reached a yearly average of 24,000,000 tons by the mid-1960s.

2. Inland Waterways.—The inland waterways have always been of considerable importance to Poland. By far the greatest stretches of inland navigation are provided by the Vistula and Oder and their main tributaries. The low sandy banks, the fast-flowing streams, and the tendency to flood after the spring thaw necessitated regulation and canalization. The interconnecting glacial valleys provided means of linking by short canals a whole series of east-west tributaries and so, eventually, the main river systems of Germany, Poland, and the U.S.S.R. Thus the Oginski and Royal canals (built in the 18th century, north and west of Pinsk, now in the U.S.S.R.) and the Augustow Canal (1825) joined the Vistula and Bug with the Neman, Pripet, and Dnieper. The Bydgoszcz (Bromberg) Canal (1773–74) was used for barge traffic between Germany and East Prussia; it linked Königsberg (now Kaliningrad in the U.S.S.R.) with the Oder and central Germany by way of the sheltered lagoons of the Baltic coast, the canalized Nogat distributary of the Vistula, and the Brda and Notec rivers. This canal was linked in 1949 through Lake Goplo with the canalized Warta River. In 1959 a short canal was opened between Warsaw and the lower Bug to avoid the navigational hazards at the confluence of that stream with the Vistula. In the 1960s the Vistula River between Warsaw and Torun was being canalized. The Upper Silesian coalfields are served by the Gliwice Canal leading into the Oder.

3. Air Services.—The Polish state-owned airline, Lot, provides services to and from a number of foreign capitals, including Moscow, Paris, Brussels, Copenhagen, Amsterdam, and Athens, while regular internal services link Warsaw with Szczecin, Poznan, Danzig, Wroclaw, Katowice, Cracow, and Rzeszow.

4. Postal Services and Telecommunications.—All these services are state controlled. By the mid-1960s there were more than 7,000 post offices, and more than 675,000 telephones were in use. There were more than 5,700,000 radio-receiving sets and about 1,300,000 television receivers.

POLARIMETRY is the science of measuring the angle of rotation of the plane of polarized light (see LIGHT: Polarization and Electromagnetic Theory).

Polarimetry is primarily of interest to the chemist, because many compounds, either in the pure state or in solution, possess the power of rotating the plane of polarization of a beam of polarized light. The phenomenon is displayed by compounds which lack a centre of symmetry in their molecular or crystalline structure, such that the compound and its mirror image are not superimposable. This situation most commonly results from the presence of a carbon atom which is covalently bound to four different atoms or groups of atoms. The angle through which the plane is rotated varies directly with the length of the light path through the sample and, in the case of solutions, with the concentration. For a given path length and concentration, the angle depends on the wavelength of the light, the temperature, and the nature of the sample and its solvent, if any. Substances which are capable of producing this effect are said to be optically active. They are characterized by a constant known as the specific rotation, designated by the symbol $[\alpha]$, usually accompanied by a subscript letter to indicate the wavelength and a superscript number for the temperature. Thus, $[\alpha]_D^{20}$ means that the value was determined at 20° C with the D-line of sodium as light source. The specific rotation is defined by the relation,

$$[\alpha] = \frac{a}{dc}$$

where a is the observed angle of rotation in degrees, d is the length of light path through the sample in decimetres, and c is the concentration in grams per millilitre.

FROM G. W. EWING, "INSTRUMENTAL METHODS OF CHEMICAL ANALYSIS"; BY COURTESY OF MC GRAW-HILL BOOK CO., INC.

DIAGRAM OF A CONVENTIONAL POLARIMETER

The angle of rotation is measured with a polarimeter (see figure). Monochromatic radiation, polarized by a Nicol prism (see LIGHT, fig. 13), is passed through the sample and a second Nicol (the analyzer) to the eyepiece for visual observation. Between the first Nicol and the sample a small, auxiliary Nicol is so placed as to cause a slight modification of the polarization angle of one-half of the light beam. This permits visual balance of the two half-beams at an intermediate level of intensity between dark and light, as the eye is most sensitive under such conditions. Several manufacturers offer completely automatic or semiautomatic recording instruments which operate on similar principles.

The chief application of polarimetric analysis is in the sugar industry, since sucrose has a much greater specific rotation than impurities likely to be present. Many other compounds, principally organic, are optically active; some are of biological and pharmacological significance.

Wheland, *Advanced Organic Chemistry*, 2nd ed., pp. 130 ff. (1949); Galen W. Ewing, *Instrumental Methods of Chemical Analysis*, 2nd ed., pp. 151 ff. (1960). (G. W. E.)

POLAROGRAPHY (POLAROGRAPHIC ANALYSIS, VOLTAMMETRY), an electrochemical method of analyzing solutions of reducible or oxidizable substances, was invented by Jaroslav Heyrovsky at Charles University, Prague, Czech., in 1922.

The majority of the chemical elements can be determined by polarographic analysis, and the method is applicable to the analysis of alloys and to various inorganic compounds. Polarography is also used to identify many types of organic compounds, and to study chemical equilibria and rates of reactions in solutions.

The solution to be analyzed is placed in a glass cell containing two electrodes. One electrode consists of a glass capillary tube (internal diameter about 0.05 mm., or 0.002 in.) from which mercury slowly flows in drops (dropping mercury electrode), and the other is a pool of mercury or some other nonpolarizable electrode. The cell is connected in series with a galvanometer (for measuring the flow of current) in an electrical circuit that contains a battery, or other source of direct current, and a device by means of which the voltage applied to the electrodes can be varied from zero up to about two volts. With the dropping mercury electrode connected (usually) to the negative side of the polarizing voltage, the voltage is increased by small increments and the corresponding current is observed on the galvanometer. The current is very small until the applied voltage is increased to a value large enough to cause the substance being determined to be reduced at the dropping mercury electrode. The current increases rapidly at first as the applied voltage is increased above this critical value, but gradually attains a limiting value and remains more or less constant as the voltage is increased further. The critical voltage required to cause the rapid increase in current is characteristic

of, and serves to identify, the substance being reduced (qualitative analysis). Under proper conditions the constant limiting current is governed by the rate of diffusion of the reducible substance up to the surface of the mercury drops, and its magnitude is a measure of the concentration of the reducible substance (quantitative analysis). Limiting currents also result from the oxidation of certain oxidizable substances when the dropping electrode is the anode.

In 1925 J. Heyrovsky and M. Shikata invented an instrument called the polarograph, which automatically applies an increasing voltage to the dropping electrode cell and photographically records the resulting current-voltage curve. Curves thus recorded are called polarograms.

When the solution contains several substances that are reduced or oxidized at different voltages, the polarogram shows a separate current increase (polarographic wave) and limiting current for each. The method is thus capable of detecting and determining several substances simultaneously, and is applicable to relatively small concentrations, e.g., 10^{-6} up to about 0.01 moles per litre, or approximately 1 to 1,000 parts per 1,000,000.

In recent years specialized measuring techniques, using superimposed alternating or pulsed voltage impulses, have been used to study mechanisms of reactions at the dropping mercury electrode.

POLAR REGIONS: see ANTARCTICA; ARCTIC, THE.

POLDING, JOHN BEDE (1794–1877), English Benedictine, first Roman Catholic bishop in Australia, first archbishop of Sydney, and a man full of zeal for the spiritual welfare of the isolated settlers of the new continent and of the numerous convicts who were constantly being shipped from England, was born at Liverpool on Oct. 18, 1794. He became a Benedictine monk and quickly rose to positions of influence and trust in his order. Consecrated as the first Australian bishop, he arrived at Sydney in September 1835. There were but four Roman Catholic clergymen to meet him. The new bishop vigorously set to work dividing up his territory into missionary districts and providing priests, churches, and schools as rapidly and extensively as he could. Visits to Europe enabled him to procure help for his people in various ways. From one of these visits he returned in March 1843 as archbishop of Sydney (appointed April 10, 1842). Nevertheless his kindness and humility were more evident than his administrative gifts. He died on March 16, 1877.

See P. F. Moran, *History of the Catholic Church in Australasia*, (1894); H. N. Birt, *Benedictine Pioneers in Australia*, 2 vol. (1911). (E. McD.)

POLE, the name of two families famous in English history.

The de la Poles, earls and dukes of Suffolk, were descended from Sir WILLIAM DE LA POLE (d. 1366), of Kingston-upon-Hull, the richest English merchant of his age. The parentage of Sir William, his elder brother, Sir RICHARD (d. 1345), and his younger brother, JOHN, remains uncertain; they may have been sons of Sir Lewis de la Pole (d. 1294) and grandsons of Gruffydd ap Gwenwynwyn (d. 1286), prince of Powys.

Sir Richard, vintner of Hull and London, made loans to Roger Mortimer's government (1327–30) and later to Edward III; he was king's butler from 1327 to 1331 and from 1333 to 1338. Joan, Lady Cobham (d. 1434), whose fourth husband was the Lollard Sir John Oldcastle, was the daughter and heiress of Sir Richard's grandson, Sir John de la Pole (d. 1380).

Sir William (d. 1366), first mayor of Hull (1332–33) following the grant of a royal charter in 1331, represented the borough in five parliaments between 1332 and 1338. At the beginning of the Hundred Years' War, he was Edward III's chief financial agent and in just over a year (1338–39) he loaned the king more than £100,000; in 1339 he was made 2nd baron of the exchequer and created knight banneret. De la Pole was among those arrested in December 1340 after the king's return from Flanders and charged with frauds in connection with the wool transactions; his lands and goods were forfeited and he remained in prison until May 1342. He organized the "English Company" which was granted a monop-

oly of the wool export trade in 1343. Despite his losses in 1340–41, he possessed great wealth and was the first English financier to found a noble house. His eldest son, MICHAEL DE LA POLE (c. 1330–89), acquired estates in Suffolk by his marriage with Katharine, daughter of Sir John Wingfield, and was summoned to Parliament as a baron before his father's death. He served in France under Edward the Black Prince and John of Gaunt, and in 1380 led the embassy which arranged Richard II's marriage with Anne of Bohemia. In 1383 he became chancellor of England, and his heir, MICHAEL (d. 1415), married Katharine, daughter of Hugh, 2nd earl of Stafford, a descendant of Edward I. When the earldom of Suffolk was revived in de la Pole's favour in August 1385, a royal grant gave him the East Anglian lands formerly held by the De Ufford earls of Suffolk. His opponents, led by the king's uncle, Thomas, duke of Gloucester, obtained his dismissal from the chancellorship in the Parliament of October 1386, and he was impeached, convicted, and imprisoned. Richard II soon released his fallen minister and Suffolk was the leader of the court party in the struggle that followed. After being charged with treason by the victorious lords appellant in November 1387, Suffolk escaped abroad and was sentenced to death and forfeiture in the Merciless Parliament of February 1388. He died in exile in Paris in 1389.

After Richard II's triumph in 1397, the sentence on Suffolk was reversed and in the Shrewsbury Parliament of January 1398, his son, Michael, was restored to the earldom. (For his descendants, see SUFFOLK, EARLS AND DUKES OF; SUFFOLK, WILLIAM DE LA POLE, Duke of; POLE, RICHARD DE LA.)

Another family of the name of Pole, having no kinship with the house of Suffolk, owed their advancement and their fall to a match with a princess of the royal house. SIR RICHARD POLE (d. 1505), a Buckinghamshire knight, was the son of Geoffrey Pole, a squire whose wife, Edith St. John, was half sister to Henry VII's mother, Lady Margaret Beaufort. About 1491 Sir Richard married the Lady Margaret, daughter of George, duke of Clarence (d. 1478), a brother of Edward IV.

In 1513 Henry VIII created Sir Richard's widow countess of Salisbury, as some amends for the judicial murder of her brother, Edward, earl of Warwick, in 1499. Her eldest son, HENRY (d. 1539), henceforth styled Lord Montague, was summoned to Parliament as a baron in 1529. Until the king's marriage with Anne Boleyn (1533), the countess of Salisbury was governess of her godchild, the Lady Mary (afterward Mary I). When her third son, Reginald, Cardinal Pole (d. 1558), published his *Pro ecclesiasticae unitatis defensione*, the whole family fell under the displeasure of the king, who resolved to make an end of them. The Lord Montague was the first victim, beheaded in 1539 on a charge of treasonable conversations, on evidence exacted from his brother, SIR GEOFFREY POLE (d. 1558). In 1541 the aged countess, attainted in 1539 with her son Montague, was also executed; a woman of great piety, she is among the English martyrs who have been beatified. Sir Geoffrey Pole joined the cardinal in exile and returned with him at Mary's accession. His sons ARTHUR and EDMUND, taken in 1562 as plotters against Queen Elizabeth, were committed to the Tower of London, where they died after eight years of imprisonment. See also POLE, REGINALD.

POLE, REGINALD (1500–1558), English cardinal and archbishop of Canterbury, who, at the accession of Mary I, reconciled England with the Holy See and became a close counselor of the queen, was born at Stourton castle, Staffordshire, in March 1500, the third son of Sir Richard Pole and Margaret, countess of Salisbury, a niece of Edward IV. Intended for the church, he spent five years at the grammar school founded by John Colet at Sheen, where his kinsman Henry VIII contributed to the cost of his education. In his 13th year he went to Oxford, matriculating from Magdalen college. Thomas Linacre and William Latimer were among his tutors. He took his B.A. in 1515. In 1518 the

king appointed him to the deanery of Wimborne and then to two prebends in Salisbury cathedral. In 1521 he went, with an annual grant of £100 from the king, to continue his studies at Padua, where during the next few years he corresponded with Desiderius Erasmus and formed friendships with Pietro Bembo, Christophe de Longolius, and other prominent humanists. He paid a brief visit to Rome for the 1525 jubilee.

Two years later he returned to England and was appointed dean of Exeter. He showed, however, little desire to desert his studies for a more active career; and it is possible that Thomas Cromwell, by recommending to him the precepts of Niccolò Machiavelli, helped to encourage this distaste for public life. When the question of Henry VIII's "divorce" from Catherine of Aragon arose, Pole at first sought to avoid taking part on either side. In 1529 he obtained the king's leave, and £100, to continue his studies at the University of Paris. The following year, however, by the king's order he helped to secure that university's pronouncement in favour of the divorce. On returning to England he was offered the archbishopric of York, vacant by Thomas Wolsey's death, but was required first to declare his opinion about the divorce, Henry not wishing to confer so great an honour upon an adversary. Pole suggested that he was ready to satisfy the king, but then apparently changed his mind, for in a stormy interview at York place he roundly denounced the royal policy. He later wrote to Henry, explaining his reasons against the divorce, and in January 1532 he received permission to go abroad again, without losing the revenues of his benefices. After a brief stay at Avignon, he settled once more at Padua and devoted himself to the serious study of theology. These studies soon led him to become a prominent member of the group of Catholic reformers, headed by Gasparo Cardinal Contarini, Giovanni Giberti and Giampietro Carafa, who were eager to reform ecclesiastical abuses but regarded the maintenance of papal supremacy as necessary to preserve the unity of Catholic Christendom.

At this point in his development his relations with Henry VIII reached their crisis. In February 1535, after the king's final break with Rome, Pole was called upon to make a formal statement of his opinion about the divorce and the royal supremacy. The executions of Bishop John Fisher and Sir Thomas More (June and July 1535) gave him grim warning of the fate which his answer might bring upon his family as well as upon himself; and the task of answering was not made easier by the genuine admiration which hitherto he had felt for Henry or by his reluctance to abandon all hope of reconciliation. Thus he took a year to write his reply and by the time it was dispatched to England (May 1536) it had grown into a full-sized book. Although later published, without Pole's consent, under the title *Pro ecclesiasticae unitatis defensione* (usually known as *De Unitate*), it was meant for the king's eye alone. It contained a severe attack on the royal policy and a strong defense of the pope's spiritual supremacy.

In July 1536, Paul III summoned Pole to Rome to serve with Contarini, Giberti, Carafa and others on the commission to consider the reform of church discipline. After some hesitation, caused by letters from his mother and brother emphasizing the dangers that his conduct might lead them into, he eventually obeyed this papal call. In December he was made a cardinal and by February 1537 the commission's report, *Consilium de emendanda ecclesia*, was completed. This most important document trenchantly summarized the outstanding abuses in the church and pointed to the remedies with plain-spoken directness. Pole's share in this notable work was hardly completed when a new task was thrust upon him. Paul III, who had already prepared a bull of deposition and excommunication against Henry VIII, now appointed Pole legate *a latere* for England and sent him to persuade the Catholic powers to take advantage of the difficulties created for Henry by the Pilgrimage of Grace. The mission was ill-timed and quite unsuccessful. The pilgrimage had been crushed almost before Pole left Rome (February 1537); Francis I refused to let him stay in France; Charles V's representative would not admit him to the Netherlands; Henry would not negotiate with him in his capacity as papal legate; and in August 1537 the pope recalled him to Rome. A second mission in 1538–39 to persuade Charles

and Francis to enforce the bull resulted in an equally humiliating failure and Pole, his life threatened by Henry's agents, sought refuge with his old friend Jacopo Sadoletto at Carpentras before returning to Rome at the end of 1539. Meanwhile the royal vengeance had fallen upon his family in England. His eldest brother, Lord Montague, and his cousin, the marquess of Exeter, were executed in 1538; his mother and he himself were attainted in 1539; and his mother executed in 1541.

On Aug. 21, 1541, Pole was appointed legate of the *Patrimonium Petri*, the oldest of the papal states, and took up his residence at Viterbo. There he gathered around him a group which included Marc-Antonio Flaminio and Vittoria Colonna, the poetess and friend of Michelangelo. With them he discussed many of the great theological questions raised by the German reformers and by the Spanish reformer Juan de Valdes. Justification by faith, the burning question of the day, was a special subject of discussion. Pole's own attitude at this time may be best summed up in his advice to Vittoria Colonna, that she should believe as though she could be saved by faith alone and act as though she could be saved by works alone. His open-mindedness, the leniency of his rule at Viterbo, and his reluctance to abandon all hope of healing the divisions of Christendom were, however, by now beginning to separate him from Carafa and those who felt that, after the failure of Contarini's negotiations with the Lutherans at Ratisbon (Regensburg) (1541), the time had come for sterner measures to defend and define the Catholic faith. Indeed, after the conversion to Protestantism in 1542 of Vittoria's friend Bernardino Ochino and of Peter Martyr, whom Contarini had defended, the newly established Roman Inquisition, headed by Carafa, regarded the entire Viterbo circle as no better than heretics.

Nevertheless Pole was one of the three legates appointed in 1542 to open the Council of Trent and, when the council eventually met in December 1545, he was one of the three who presided over its session, after journeying to Trent by a devious route for fear of assassins hired by Henry VIII. He urged the council very strongly to reform the abuses as well as to define the doctrines of the church and when the question of justification came up for discussion he entreated the fathers to study the subject well before committing themselves to a final decision. Soon after this discussion began, however, his health broke down and he retired to Padua (June 1546). There is no reason to believe that this was a feigned illness. It is true that the council did not accept the compromise on justification that Contarini had put forward at Ratisbon and which Pole still favoured. But Pole kept in touch with its proceedings by letter; his view was well represented in the discussions by Seripando; and he accepted readily enough the decree that the council finally passed.

On the death of Paul III (November 1549) Pole, thanks to Charles V's support, came near to election as pope. After hesitating to let himself be acknowledged by acclamation before all the French cardinals had arrived, he just failed to obtain the necessary two-thirds of the votes. In the end the French and imperialist factions compromised by electing Julius III. Under him reform made little headway. Pole lost his legacy at Viterbo (1550), was openly (though vainly) denounced by Carafa for heretical leanings, and about 1553 retired to the monastery of Maguzzano on Lake Garda.

However, on the accession of Mary Tudor (July 1553), the pope at once appointed Pole legate for England. Yet even now his course was not smooth. He had often been spoken of as a possible husband for Mary—he was still only in deacon's orders, so that a papal dispensation might have been obtained—and Charles V was therefore determined to keep him out of England until Mary's marriage to his own son Philip had been arranged. Moreover Pole himself thought this marriage a mistake, although he failed to convince the pope. Even when Philip and Mary were safely married (July 1554), other obstacles remained, notably the English parliament's insistence upon adequate guarantees that lay holders of confiscated church lands should not be disturbed. Thus it was not until Nov. 20 that he landed at Dover. Ten days later he formally absolved the realm and received it back into the Roman fold. On Dec. 24 he issued a decree guaranteeing holders of church property against all ecclesiastical censures, though he would

not add that they might hold it with a clear conscience. On Philip's departure in September 1555, Mary turned more and more to Pole for advice on all matters. He was not responsible for the religious persecution that disfigured the last four years of her reign, although he did nothing to stop it and occasionally himself issued commissions to repress heresy. First and foremost he was still the Catholic reformer. In November 1555 he assembled at Westminster a national synod of the two convocations, which quickly agreed to measures to enforce clerical residence, reduce pluralism, increase preaching, compel priests to set a good example to their flocks, and to provide a new book of homilies and a new translation of the New Testament. On Thomas Cranmer's deposition, Pole became archbishop of Canterbury (March 1556), after being ordained priest two days before, and sought to enforce these decrees by a metropolitanical visitation. He also attempted to refound some of the monasteries and sent commissioners to carry out a visitation of the universities. All this work, however, went forward too slowly to take any firm root within the few short years of Mary's reign.

Moreover, Pole was thwarted by the papacy itself. In May 1555 Carafa had become pope as Paul IV. He adopted a violent anti-Spanish policy which soon brought renewal of the war between France and the Habsburgs. Pole's efforts to prevent the conflict only infuriated Paul. In April 1557 he was deprived of his legatine authority and in June, after England's declaration of war on France, he was summoned to Rome, the aged William Peto being appointed legate in his place. At the same time the Pope inveighed against Pole as a heretic and handed his friend Cardinal Morone over to the Inquisition. Doubtless Pole would have shared this fate had Mary not prevented the delivery of the pope's summons. Instead, he remained in England until, broken as much by the unmerited blow of the papal disgrace as by ill health, he died at Lambeth on Nov. 17, 1558, 12 hours after Mary. He was buried at Canterbury, near the site of the shrine of St. Thomas à Becket.

BIBLIOGRAPHY.—G. Quirini's *Epistolarum R. Poli collectio*, 5 vol. (1744–57), also contains the life written in Italian by Pole's secretary Beccatelli, which Andrew Dudith translated into Latin (*Vita Poli cardinalis*, 1563). See also A. Zimmermann, *Kardinal Pole, sein Leben und seine Schriften* (1893); W. Schenk, *Reginald Pole, Cardinal of England* (1950). (R. B. Wm.)

POLE, RICHARD DE LA (d. 1525), claimant to the English crown, was the youngest son of John de la Pole, 2nd duke of Suffolk (d. 1491/1492), and Elizabeth, sister to King Edward IV. Since Edward IV's brother and successor Richard III died childless, and since Edward's own sons disappeared in the Tower (probably murdered by their uncle's orders), the de la Poles inherited the Yorkist claim to the throne, a claim strengthened when Richard III named Suffolk's eldest son John (d. 1487), earl of Lincoln, as his successor. The claims of the attainted line of Clarence, represented by the young earl of Warwick, were passed over under Richard III but were sufficiently alive under Henry VII to postpone the full assertion of the de la Pole claim until Warwick's execution in 1499. After the accession, in 1485, of the first Tudor, Henry VII, the family therefore lived under suspicion, nor did it help that Lincoln joined Lambert Simnel's rebellion (1487), which cost him his life. The claim thus devolved upon the second brother, Edmund, earl of Suffolk (d. 1513). After years of waiting, the earl fled abroad in 1499; and though he returned briefly he fled again in 1501, this time accompanied by his brother Richard. The brothers tried to interest the emperor Maximilian in their cause, but in 1502 Maximilian agreed with Henry VII on terms which included dropping the Yorkist claimants. Edmund, attainted as a traitor in 1504, was imprisoned in Burgundy in that year and surrendered to Henry in 1506, on condition that his life be spared. He lived a prisoner in the Tower until Henry VIII carried out the old sentence against him in 1513.

Meanwhile Richard had led an adventurous life, escaping (1504) the pressing attentions of his brother's creditors at Aachen, taking service with King Ulászló II of Hungary, and establishing something of a reputation as a *condottiere*. After Edmund's death he took over the claim to the crown, calling himself duke of Suffolk. In 1512, the outbreak of war between France and England encouraged him to seek French help, and he was given an army that

he might have used against England if time had served. However, when peace was concluded in 1514, Louis XII of France at once dropped him and forced him to leave the country. He went to live at Metz, but maintained his contacts with France. Louis XII's successor Francis I found him useful both as a man of military capacity and as a weapon in his complex diplomacy. In 1523, when he wished to prevent English assistance to the Habsburgs, he encouraged an intrigue which was meant to restore the Yorkist claimant to England with the help of an exiled claimant to the Scottish throne. Though nothing came of this, Richard de la Pole remained in Francis' service, accompanied him to the war in Italy, and was killed in the Battle of Pavia (1525). His death terminated the claims of the main Yorkist line and ended a threat to the Tudor throne which, however improbable in retrospect, seemed real enough to a generation that had seen the crown change hands several times as the result of dynastic civil war.

See J. D. Mackie, *The Earlier Tudors, 1485-1558* (1952).

POLE AND POLAR, in mathematics. If from a point P outside a circle the two tangents to the circle be drawn, the line joining the points of contact is called the polar of the point P , and P is called the pole of the secant line. If P is on the circle, the two tangents coincide and the polar of P is the single tangent at P . For Q , a point inside the circle, draw two secants to the circle through it. The line joining their poles is called the polar of Q . If the polar of P passes through Q , the polar of Q passes through P . In the figure shown, \overline{AB} is the polar of P_1 ; \overline{CD} is the polar of P_2 ; line P_1E is the polar of A ; P_1P_2 is the polar of Q . The same principle applies to any conic. In space there is a corresponding theory of points and polar planes as to a sphere or any fixed quadric surface. The idea is due to C. J. Brianchon, who first applied it in 1806, but it was developed by J. V. Poncelet, and presented in final form in 1829. Later the concept was extended to other curves and surfaces, and to other configurations.

DIAGRAM ILLUSTRATING THE THEORY OF POLE AND POLAR PLANES

POLECAT (FITCH), a weasel-like carnivore of the family Mustelidae, which also includes the weasel, mink, otter, etc. Polecats (*Mustela putorius*) are confined to the northern hemisphere, being found in the central and northern parts of the European continent, east to Siberia and Mongolia and south to the Himalayas. The polecat is well known in its domesticated, albino variety as the ferret. The wild polecat is brownish above and black below, the

face being variegated with white. The fur is long, coarse and of little commercial value. This polecat is more powerful than the marten (*q.v.*) but less active, and rarely climbs trees. Its food consists of small mammals and any birds it can catch, especially poultry. It also eats snakes, lizards, frogs, fish and eggs. It is extremely blood-thirsty and hunts at night. From three to eight young are produced in April or May, after a two months' gestation. It is tenacious of life and has a fetid smell.

On the central plateau of the United States is found the black-footed ferret, *M. nigripes*, a related species with creamy-yellow fur, brown legs and black feet and tail. A related genus, *Vormela*, whose fur is white marbled with reddish spots above, extends from east Poland to Afghanistan. These animals resemble *M. putorius* in habits. In the United States, the name polecat is often applied to skunks. See also FERRET; WEASEL.

POLEMONIACEAE, the phlox family, consisting of dicotyledonous herbs, rarely shrubs or small trees, with about 13 species native in Europe, Asia and America, chiefly North America. Leaves are alternate or opposite, simple or compound, the flowers bisexual, mostly regular and often showy, especially in the garden forms. Among the well-known genera are *Phlox*, *Polemonium*, *Cobaea* and *Gilia*.

See PHLOX.

(J. M. BL.)

POLENTA, DA, a despotic Italian family which ruled Ravenna (*q.v.*) during the 14th and the first half of the 15th centuries. They first appear in the 12th century as members of the minor feudal gentry, and took their name from the castle of Polenta (near Bertinoro), for which they were indirect vassals of the archbishop of Ravenna. They soon became prominent in the factions of Ravenna, and it was as leader of the Guelphs that Guido da Polenta (called Guido Minore), or the Younger, began to exercise control over that city in the last quarter of the 13th century. At the same time Cervia came under Polenta rule. Guido, whose daughter Francesca is famous in the history of the house of Malatesta (*q.v.*), was succeeded by his sons Bernardino and Lamberto and then, in 1316, by Guido Novello, remembered as a friend of Dante in exile and an early patron of writers and artists. In 1322 Guido was dispossessed by his cousin Ostasio I, and thereafter throughout the 14th century the family history is marked by successive acts of domestic murder and atrocity, as one Polenta seized power violently from another. Like other lords in the Romagna, the Polenta were alternately loyal and rebellious subjects of their nominal overlord, the pope, and like others they were from time to time invested with the power of papal vicars.

From the late 14th century the Polenta came increasingly under the control of the Venetians, whose policy on the Adriatic mainland of Italy became steadily more aggressive. As early as 1410 Obizzo da Polenta promised the reversion of his state to Venice if his sons should prove unwilling satellites; and on these grounds the Venetians finally took Ravenna from the Polenta in 1441. Soon afterward the last of the family died as exiles on the island of Crete, then under Venetian domination.

POLESIE (meaning in Polish and Russian "cleared forest land") is the largest swamp and bog area in Europe, covering the major part of the Pripyat (Prypec) river basin. It has roughly the form of a triangle with its apex near Brest (Brzesc Litewski) and its base between the points where the Berezina in the north and the Teterev in the south join the Dnieper River. Polesie was settled relatively early because food was abundant (fish in the rivers and the lakes, game in the forests) and because the area was easy to defend. The oldest known inhabitants were the Dregovichs, a Slavonic tribe, whose neighbours to the northwest were Lithuanians, and to the southeast other Slavs—ancestors of the modern Ukrainians. In the 11th century the local principality of Turov (on the Pripyat) was part of Kievan Russia. Conquered by Lithuania in the 14th century, it became part of Poland after the Polish-Lithuanian union of 1569. At that time Polesie formed the *województwo* (province) of Brzesc Litewski. After the partitions

YLLA FROM RAPHO-GUILLETTE

POLECAT (*MUSTELA PUTORIUS*)

of Poland the country was divided among the Russian *guberniye* of Grodno, Minsk, and Volhynia. When Poland was restored after World War I, western Polesie became a Polish *województwo*, while eastern Polesie was divided between the Belorussian and the Ukrainian Soviet Socialist republics; but after World War II the whole of Polesie was divided between the two latter republics.

(K. SM.)

POLE STAR (POLARIS), the (naked-eye) star nearest the north celestial pole, is the brightest star in the constellation Ursa Minor (*q.v.*), hence its Bayer designation, α Ursae Minoris. The closeness of the star to the pole (minimum distance about 27' in the year 2102) causes its apparent position to remain nearly constant all night and all year. The location and moderate brightness of Polaris make it a convenient object for navigators and surveyors to use in determining latitude and north-south direction in the northern hemisphere.

Polaris, a single star to the naked eye, is a system of three stars. A faint companion is visible in a small telescope; spectrographic observations indicate the presence of a third star very close to the brighter of the visual pair.

The bright star is a pulsating variable of the classical Cepheid type, undergoing changes in diameter and in brightness during a four-day period.

(E. R.)

POLE VAULTING, the art of jumping over an obstacle with the aid of a pole. Originally a means of clearing objects, such as ditches, brooks, and fences, pole vaulting for height, clearing a bar supported by two uprights, became a competitive sport. In competition, each vaulter is given three chances to clear a specified height. The bar, which rests on the uprights set not less than 12 ft. apart, is raised progressively until a winner emerges. Ties are broken by a "count back" based on fewest failures and fewest attempts throughout the contest. The pole may be of any material (fibre glass became the most effective, and popular, in the early 1960s) and of any length or diameter. A slideway, or box, is sunk into the ground, the back of which is placed directly below the crossbar. The pole is thrust into this box. A soft pit, generally of sawdust or foam rubber, is provided for the vaulter's landing.

Requirements of the athlete include a high degree of coordination, timing, speed, and gymnastic ability. The modern vaulter approaches the takeoff with great speed, carrying the pole with his hands about 2½ ft. apart. As the stride next before the spring is completed, he performs the shift, which consists in advancing the pole toward the slideway (known as the advance) and at the same time allowing the lower hand to slip up the pole until it reaches the upper hand, and raising both hands as high above his head as possible before leaving the ground. He is thus enabled to exert the full pulling power of both arms to raise his body and help the swing-up of his legs. There are two factors the pole-vaulter bears in mind—one is height and the other is carry. Height gives him the elevation, and carry takes him across the bar.

The modern pole-vaulter generally uses the following techniques: A long run of approximately 100 to 150 ft., great speed down the runway, and exact timing when the shift takes place, so that his hands are extended high above his head at the instant of the takeoff. He then runs off the ground (he does not jump) leaving his body hanging by the hands as long as possible, not pulling too soon. He then lets his legs swing upward and to the side of the pole. The athlete's feet should reach a point well above the crossbar, in an attempt to actually make a handstand. At this stage the vaulter shoots his legs high above the crossbar by means of a strong arm pull on the pole. He next turns his body face downward and converts his pulling force into a pushing force. The bar lies in the concavity of the stomach, so that his feet are on one side and his head and shoulders are on the other side. The athlete finally carries his body across the crossbar by what is known as the carry, which is the speed he has acquired from his run.

Astounding improvements in performance are best illustrated as follows: (1) H. B. Baxter (New York Athletic Club), in 1883, 11 ft. ½ in. (using old style), the first man to vault over 11 ft.; (2) Norman E. Dole, 1904 world's record, 12 ft. 1½ in., the first man to vault over 12 ft.; (3) Robert A. Gardner (Yale University), at

the Intercollegiate Association of Amateur Athletics of America games in 1912, 13 ft. 1 in., the first man to vault over 13 ft.; (4) Sabin W. Carr (Yale University), at the IC4-A games in 1927, 14 ft., the first man to vault 14 ft.; (5) Cornelius Warmerdam (Olympic Club), at Berkeley, Calif., in 1940, 15 ft. 1½ in., the first man to vault 15 ft.; (6) John Uelses (U.S. Marine Corps), using a fibre-glass pole, at Santa Barbara, Calif., in 1962, 16 ft. ¼ in., the first man to vault 16 ft.; (7) John Pennel (Northeast Louisiana State College), at Miami, Fla., in 1963, 17 ft. ¾ in., the first man to vault 17 ft.

Introduction of a bamboo pole, used with modern technique, added approximately a foot to the records; Warmerdam used a bamboo pole. Don Bragg achieved his world record of 15 ft. 9¼ in. (1960) with an aluminum pole. However, with mastery of the different timing and technique of fibre-glass poles, vaults of more than 16 ft. soon became commonplace. See OLYMPIC GAMES; TRACK AND FIELD SPORTS.

POLICE. In a broad sense, the term police (Lat. *politia*, the state) connotes the maintenance of public order and the protection of persons and property from the hazards of public accidents and the commission of unlawful acts; specifically, it applies to the body of civil officers charged with maintaining public order and safety and enforcing the law, including preventing and detecting crime. In its wider aspects, the term at one time also included such "public health" activities as street paving and lighting, or scavenging and sanitation, as well as applications broad enough to comprehend the entire range of government domestic policies. In modern usage, it includes various inspectional, licensing, and other regulatory activities.

A special use of the word is involved when authoritarian states set up secret political police organizations that operate independently of the regular civil police establishments. Political police are always highly centralized agencies. The Nazi Gestapo and *Schutzstaffel*, the tsarist Okhrana, the Soviet Cheka, OGPU, and NKVD, and Mussolini's *Ovra* all had common characteristics sharply distinguishing them from other civil police. Their governments may be called police states. Though democratic governments may need to protect themselves against subversion, they do not hesitate to entrust this protection to police forces charged with law enforcement in general. Lest private rights be infringed, police authority is then carefully limited and numerical strength is held within modest bounds. Under some systems the policeman bears a heavy responsibility for the manner in which he performs his law-enforcement functions, and he is personally answerable in the criminal and civil courts for abuses of his authority. With increasing experience in police management, the maintenance of adequate safeguards for both the state and its citizens is coming closer to realization, though reconciling the two will continue to require attention under all forms of government that support the exercise of substantial civil rights.

Popular governments permit much local autonomy in police administration while authoritarian states tend to centralize police control, but other factors also may produce centralized police control even in democratic countries. England, Wales, and Scotland have scores of local police forces, whereas the Republic of Ireland and the government of Northern Ireland each maintains a single police establishment. Belgium has dual police systems for the national and local levels, with municipal forces that are almost completely autonomous, whereas in Denmark all police activities are administered by functionaries of the crown. For the most part, western European countries follow the French pattern of a national police charged with the maintenance of public order, the investigation of all major crimes, and the full policing of the larger cities, together with locally recruited forces concerned with routine law enforcement duties, including local traffic control, in the smaller places. In some countries, such as France and Italy, a branch of the national police force also performs routine police duties in rural districts. Japan, under a law of 1954, centralized

all police forces under the National Defense Force; even so, a certain degree of autonomy in matters of authority, administration, and finance is left to the prefectural and larger municipal departments. In the United States and Canada, national and state (or provincial) police parallel the local police systems.

Police administration in the English-speaking countries has six major aspects: uniformed patrol, criminal investigation (detection of criminals), traffic regulation, special measures for controlling commercial "vice" (narcotics, prostitution, and gambling), regulation of the sale and consumption of intoxicating liquor, and procedures and facilities for dealing with women offenders and juvenile delinquents. (In this connection, *see* GAMBLING; INVESTIGATION, CRIMINAL; JUVENILE DELINQUENCY; LIQUOR LAW. For a general discussion *see* CRIME.)

United States.—Strictly speaking, the United States has no police system. It has about 40,000 police jurisdictions represented by the federal government, the states, the sheriffs and deputy sheriffs of 3,000 counties, a handful of county police forces independent of the sheriffs' offices, the police of 1,000 cities, and occasional constables in more than 20,000 townships, magisterial districts, or county districts, together with other minor forces in 15,000 villages, boroughs, and incorporated towns. In addition, there are a number of special districts concerned with the patrol of parks, parkways, tunnels, bridges, and aqueducts. In short, police administration follows the jurisdiction of the civil governments, whether federal, state, or local. This produces serious internal strains since in a given area there may be as many as five or six levels of police administration. It also unduly complicates the task of coordinating investigations and other police activities. However, central clearinghouses for crime records, criminal identification, and police training, and the vast interstate networks of police teletype and radio, serve in part to overcome some of the more flagrant defects. The total numbers of all full-time and part-time police, including administrative and clerical employees, in the service of these many jurisdictions in the 1960s was around 340,000, compared with an estimated 198,000 in 1940. The increase in police numbers was roughly proportionate to the population growth in the same period. The well-defined trend is away from part-time police, particularly the township constables and deputy sheriffs; but when these are found to be inadequate, state and local governments tend to create new and additional police bodies without eliminating the outworn agencies.

Local police agencies range in size from only one or two part-time employees to a highly developed force of thousands in the largest cities. The ratios of police to population generally are highest in the largest cities and decline by graduated steps. Thus, in cities of more than 250,000 population the ratio of full-time police to population was approximately 1:420 in the mid-1960s, while in places of less than 10,000 population the ratio was only about 1:770. The crime index also has been consistently higher in large metropolitan centres than in smaller cities or rural areas. Similar variations appear geographically. New England has the highest police ratios for cities over 250,000 population, the Pacific Coast for places under 25,000. Lowest ratios are most commonly found in the central states. Police strength thus is not only disproportionately greater in those parts of the country having large urban centres but it is in large degree actually concentrated in the big cities. Of the total number of police employed in about 3,700 urban places, more than half were concentrated in less than 50 cities with populations exceeding 250,000.

The inherent weakness of the smallest police establishments and the abdication of police authority by many rural functionaries combined to produce inadequate policing throughout most of the U.S. countryside. For many years this condition was ignored, but the advent of the motor age brought with it so many problems of crime control and traffic regulation that the ancient sheriff-constable system was quickly overwhelmed. A new type of police agency thereupon emerged—one destined to have a far-reaching influence upon the development of police in the United States and upon the distribution of functions among local and state governments. The 19th century witnessed several limited and tentative experiments in state police administration—in Texas, Massachusetts, and Con-

necticut—but it was not until 1905 that Pennsylvania established its state police force; and when New York and other large states followed at about the time of World War I, success of the state police idea was assured. Because these agencies were in fact wholly new, they did not inherit the old United States police tradition, parts of which were thoroughly bad. Furthermore they were able to experiment with new devices for selection, training, promotion, and discipline.

By the time of World War II every state had acquired a police agency of its own. Some of these were rudimentary in conception and limited in both authority and number of personnel. Some were charged merely with the patrol of state highways for traffic law enforcement. Others had broad enforcement powers exercised throughout populous states but especially in the rural areas where local policing was least adequate. Without exception, state police forces represented a break with the past and with the tradition of local autonomy in police management. But their numbers were nowhere great and their establishment was not accompanied by any large-scale abandonment of outworn and outdated local police units.

The federal government also was drawn more and more into the police field, because it could not be expected indefinitely to entrust the enforcement of many federal statutes to local and state police bodies. The stresses of the American Civil War brought several rudimentary investigative agencies into existence while the expansion of federal regulation encouraged the development of others. In all but a mere handful of these, law enforcement was either auxiliary to other administrative activities or was performed within a narrowly restricted area or involved in the conduct of military or naval operations.

General police jurisdiction at the national level is exercised only by the Federal Bureau of Investigation, the FBI. (*See* FEDERAL BUREAU OF INVESTIGATION.) This select corps of criminal investigators has had repeated additions to the scope of its responsibilities. The central services performed by the FBI for state and local law-enforcement agencies include maintenance of extensive crime laboratories and a uniform system of crime reporting for all jurisdictions in the United States and its possessions.

In a special category are the police organizations maintained by such federal agencies as the Treasury Department and the Tennessee Valley Authority. The police department of Washington, D.C., is wholly unique; commissioners appointed by the president administer the governmental affairs of the federal district and accordingly are responsible for law enforcement within its boundaries.

Great Britain.—Modern police administration in Great Britain stems from the establishment in 1829 of the metropolitan police in the sprawling urban and suburban area surrounding the City of London by the home secretary, Sir Robert Peel. (The popular term "bobby" to denote a policeman stems from his name.) Today the metropolitan police enforce the law in a wide circle of 700 sq.mi., most of it lying within a radius of 15 mi. from Charing Cross. The ancient City, however, which is only 1 sq.mi. in area, has only a small resident population but boasts great wealth and importance, has never been a part of the Metropolitan Police District. Under the London Government Act 1963, the Metropolitan Police District consists of Greater London (excluding the City and the Inner and Middle Temples) and parts of Essex, Hertfordshire, and Surrey.

Headquarters of the metropolitan force are at New Scotland Yard in the borough of the City of Westminster on the Thames embankment, close to the offices of the national government and the Houses of Parliament. The police commissioner of the metropolis is appointed by the crown, with the Home Office occupying the position of responsible police authority in all metropolitan police matters. The home secretary exercises direct control over this critically important law-enforcement agency. (*See* also SCOTLAND YARD.)

The commissioner of the City of London police is chosen by the mayor and aldermen, while in other cities and boroughs having their own police establishments the Watch Committee of the city or borough council appoints the chief constable. Each county

constabulary is under the control of a standing joint committee, consisting of specially designated members of the county council and justices of the peace, which selects the chief constable; but the choice of chief constable must in all cases be ratified by the Home Office.

The early county constabularies were created around 1840, primarily for the protection of rural areas, but many now are also charged with responsibility for policing towns in their areas, some of them of considerable size. This process of consolidation, which had gone on for many years, was speeded up greatly by the exigencies of World War II. Further absorption of 45 of the 47 noncounty borough forces followed application of the terms of the Police Act of 1946. Another trend toward integration is marked by the device of placing a single chief constable in command of two or more neighbouring forces.

The authorized strength of the London Metropolitan Police in the 1960s was about 20,000 but the actual strength was around 17,000; the figures for the City of London Police were about 1,000 authorized but 700 actual. The strength of the total county, city, and borough forces in England, Wales, and Scotland was approximately 92,000 authorized, 81,000 actual. Ratio of police to population throughout England, Wales, and Scotland was about 1:600, but this uniform ratio conceals great local differences due to differing population densities, differing conditions in town and country, the nature or value of property to be guarded, and any circumstances making such property unusually vulnerable.

Although the British police system is deeply imbedded in local political institutions, the national government nevertheless maintains a certain degree of surveillance over the administration of even the smallest borough forces and county constabularies and extends financial and technical aid in various important ways. This represents an effort to introduce some degree of unity and coherence into a system that in most respects is wholly decentralized. Hence, the home secretary (for England and Wales) and the secretary of state for Scotland may enforce standards of efficiency in all police establishments. They also control the conditions of police employment (appointment, promotion, discipline, compensation, etc.) through widely ranging regulations. Such controls are made effective by the grant-in-aid annually made to each police establishment, totaling one-half of the net cost of each force, including pensions. The various forces are thereby made largely dependent upon the national exchequer, for it is provided that the grants shall be made only to those meeting the required standards. Annual visitations by her majesty's inspectors of constabulary (five for the Home Office, including one woman, and one for the Scottish Office) operate to enforce compliance.

The national government provides various central facilities. It operates seven forensic science laboratories (in addition to the metropolitan police laboratory at New Scotland Yard), district recruiting offices, regional networks for wireless communication, and eight training centres serving a number of neighbouring forces in England and Wales, with a ninth serving Scotland. It also bears a special relationship to the metropolitan police that springs from the unique position and character of that force. For example, the Metropolitan Police Force through its Special Branch is charged with certain duties in the U.K. and British colonies not readily performed by any other existing body. It is responsible for the protection of the royal family, the ministers of government, and distinguished foreign visitors; for traffic and maintaining order in the vicinity of the Houses of Parliament; for guarding government buildings and taking special precautions at state functions; and for protecting against political agitators and sabotage. A special contribution of £100,000 a year is made from the exchequer for these purposes.

The Metropolitan Police Force performs a widely heralded and generally misunderstood function in investigating certain crimes committed outside the metropolitan area. For the most part these excursions are confined to cases of murder; and since they are authorized only upon the request of the local chief officer of police, their number in any one year is small. A new branch was formed in 1954 to cooperate on country crimes committed by London criminals. The Metropolitan Police Force also operates the Crim-

inal Record Office, a national registry of crimes and criminals, and publishes the daily *Police Gazette* which carries details of persons wanted for crime and of stolen property; this publication is distributed without charge to British and certain European police forces.

Commonwealth of Nations.—Canadian local police forces, unlike those in the United States, are usually under the jurisdiction of police boards or commissions comprised of the mayor, the county judge, and a police magistrate. While the county judge and police magistrate are appointed by the central and provincial governments respectively, in practice they are regarded as servants of the local community. For Canada's extensive federal police system see ROYAL CANADIAN MOUNTED POLICE. The RCMP act as provincial police except in Ontario and Quebec, which have their own provincial police forces, and as municipal police in many small communities.

Australia has a small Commonwealth police force, with restricted federal duties, but the various states maintain their own police forces. These are the smallest units; there are no separate city forces, though Canberra, the capital, has a detachment of about 25 men from the Commonwealth force. Commonwealth duties such as the registration and control of aliens, firearms, the drug traffic, and the trade in obscene literature are left to the state forces; these, however, cooperate so closely and confer so frequently that national uniformity is maintained.

(Br. S.; L. Gu.)

European Countries.—The main police forces in France are the Préfecture de Police and the Sûreté Nationale, both controlled by the Ministry of the Interior, and the Gendarmerie Nationale, a military force controlled by the minister for armed forces but made available to the Ministry of the Interior for police work. The Préfecture provides the "preventive" police force for Paris and the Seine département; its uniformed members, known as *gardiens de la paix*, are responsible for traffic and crowd control and are highly motorized. By contrast, their "plain clothes" members, who are known as the directorate of judicial police, investigate all serious crime throughout France. Their work frequently overlaps, not without occasional friction, that of the *juges d'instruction* in the early stages of a prosecution for crime. The Sûreté Nationale operates throughout the country and supervises the municipal police of provincial towns with over 10,000 inhabitants (each town having a *commissaire de police*). It has two rigidly distinct functions—"preventive" police work and criminal investigation, the latter being the concern of a Sûreté Urbaine. The Gendarmerie polices rural areas and small towns, its duties including those of military police. (See also FRANCE: *Administration and Social Conditions*.)

The state police (*Bundespolizei*) of West Germany are controlled by the Ministry of the Interior; and except in Baden-Württemberg, Bavaria, and Hesse there are no local police forces throughout the provinces of the union. Among the subdivisions of the state police, a National Boundary Guard (*Bundesgrenzschutzpolizei*) patrols the frontier of the German Democratic Republic, and a Criminal Investigation Department (*Bundeskriminalamt*) maintains a central information index, links with Interpol, technical laboratories, and specialist officers for dealing with particular crimes. All criminal investigation work is governed by a code of criminal process, arrests being permissible only under rigidly prescribed conditions, which vary to some extent in the various provinces. (See also GERMANY: *Administration and Social Conditions*.)

The Italian Corps of Agents of Public Safety (*guardia di pubblica sicurezza*), a part of the national armed forces, is responsible to the Ministry of the Interior for the protection of life and property and the prevention of crime throughout Italy. It has three sections: the territorial, operating from fixed police stations, with a central bureau (*questura*) in each province; the *mobile*, heavily armed and specially trained for dealing with strikes, riots, and revolutionary movements; and the special section, which controls road traffic and railways and guards the frontiers. The larger towns, such as Rome and Milan, have city police forces, but their duties are confined to traffic control. The Agents of Public Safety

enforce all the major laws and are responsible for public safety. The Ministry of the Interior also maintains a Carabinieri, which has ordinary police duties but is also a military corps. (See also ITALY: *Administration and Social Conditions*.)

U.S.S.R.—The MVD (*Ministerstvo Vnutrennykh Del*) is the nationwide police system at union-republic level. The MVD of the U.S.S.R. guides the activities of the MVD's of the autonomous republics. It polices the rural districts and the provincial cities of the larger republics and is entrusted with the security of public order and the protection of state property; many of its preventive purposes are achieved by installing secret agents in factories and offices. The Moscow militia, which has 134 militia precincts, comes under that city's own administration of internal affairs—a department of the executive committee of the Moscow Soviet of Working People's Deputies. It maintains law and order, investigates crimes for the district prosecutors, enforces passport regulations, and controls road traffic.

For the international police network known as Interpol, see INTERNATIONAL CRIMINAL POLICE ORGANIZATION. See also MILITARY POLICE; and references under "Police" in the Index.

(Br. S.; L. Gu.)

POLICE POWER is a term used in U.S. constitutional law to describe the permissible scope of state legislation. In spite of its importance, police power is not mentioned in the U.S. constitution; the concept was created by the courts to reflect the conclusion that an approved law did not violate specific constitutional prohibitions—especially the 14th amendment's provision that no state may "deprive any person of life, liberty or property without due process of law."

During the decades immediately preceding 1937, while the U.S. supreme court was forcefully using the due process clause to outlaw social and economic controls, such as minimum wage and maximum hour laws, an important step in the court's reasoning was a narrow definition of the police power. The freedom of labour to bargain was thought of as a liberty protected under the due process clause; an invasion of this liberty could be justified only by a proper exercise of the police power. The critical point in the court's reasoning was the further assertion that the state's police power existed only for certain limited objectives which the court frequently described as the promotion of "health, safety and morals."

Under this formula much social and economic legislation could be outlawed. Limiting the hours of work might not directly affect health, except in unusual situations such as underground mines and smelters; through this approach the supreme court in 1905 invalidated New York's 60-hour maximum work week for bakers. The court similarly concluded that minimum wage legislation did not fit under any of the permitted headings of the police power. Thus in 1923, the court invalidated the establishment of minimum wages for women, observing: "It cannot be shown that well-paid women safeguard their morals more carefully than those who are poorly paid." Even in cases where the police power was said to extend to "health, safety, morals and welfare," the court's early

decisions indicated that it was physical, rather than economic or social, welfare which fell within the permissible scope for legislation.

In 1937, notably first in a decision upholding a Washington state minimum wage law (*West Coast Hotel Co. v. Parrish*, 300 U.S. 379), the supreme court sharply altered its approach to allow wide latitude for social and economic legislation; in the course of this development the court virtually abandoned the police power concept as a means of limiting legislative power. For example, in the 1952 *Day-Brite* case upholding a state law which required that workers be paid for time spent going to the polls on election day, the court's opinion declared that the police power "is not confined to a narrow category" but "extends to all the great public needs." Although the validity of aesthetics as a goal of regulation was once in doubt, the court in 1954 sustained a program of urban development, declaring that the state may legislate to make the community "beautiful as well as healthy"; the goals of legislation may be "spiritual as well as physical, aesthetic as well as monetary." While police power as a concept for limiting governmental objectives thus was virtually abandoned by the supreme court, state supreme courts in construing their own state constitutional provisions in many cases continued the earlier approach which requires that legislation be justified under distinct and traditional headings.

Police power has occasionally been invoked to sustain rather than to invalidate legislation. This has been true in dealing with laws which impair the value of property, e.g., by shutting down a still on the advent of prohibition or by restricting the use of property through zoning; the court has sustained such legislation on the ground that effective exercise of the police power justified the restriction. But this reference to police power is only another way of saying that constitutional provisions for the protection of property, such as those of the 5th and 14th amendments, cannot have been intended to block the necessary processes of government even though some financial loss may result. In similar manner, the police power has been invoked in deciding whether laws, such as those suspending mortgage obligations in times of economic depression, violate the constitutional prohibition against impairing the obligation of contracts. In all these cases, resolving the question whether public or private interest must yield has called for balancing delicate and elusive considerations applicable to each individual case; the general concept of police power, although often invoked, has not in reality supplied the specific materials for decisions.

POLIDORO CALDARA DA CARAVAGGIO: see CARAVAGGIO, POLIDORO DA.

POLIGNAC, a noble family of France, represented in the 20th century by one line of ducs and princes de Polignac and by another of comtes.

The first viscounts of Polignac (in the modern *département* of Haute-Loire) were practically independent rulers of Velay, the country where the Loire rises, at least from the 1050s, perhaps from 860. Their ultimate heiress, VALPURGE, was married in 1349 to Guillaume III de Chalençon, whose descendants assumed the Polignac name in 1421. The actual power of the house declined as feudalism broke down, but it maintained its exalted rank in the nobility; and in the ninth generation after Guillaume de Chalençon it emerged into political prominence with MELCHIOR (1661–1741), known first as the abbé, then as the cardinal de Polignac. Early experienced in diplomatic affairs between France and Rome, the abbé was sent as Louis XIV's ambassador to Poland in 1693. There he procured the abortive election of François Louis de Bourbon, prince de Conti (q.v.), as king of Poland in 1697. After a temporary disgrace, he was elected to the French Academy in 1704. During the War of the Spanish Succession he played a major part in the negotiations at Gertruydenberg (1710) and at Utrecht (1712) before becoming a cardinal (creation *in petto* 1712, published 1713). He was exiled for participation in the Cellamare plot of 1718 (see MAINE, LOUIS AUGUSTE DE BOURBON, DUC DU),

but was French *chargé d'affaires* in Rome from 1724 to 1732 and was made archbishop of Auch in 1726. He died in Paris on Nov. 21, 1741. His long Latin poem, *Anti-Lucretius*, first printed in 1747, largely against Pierre Bayle's philosophy, went through many editions and translations.

The cardinal's grandnephew, ARMAND JULES FRANÇOIS (1745-1817), was married in 1767 to Yolande Martine Gabrielle de Polastron. She became a great favourite of Queen Marie Antoinette, and he was created duc de Polignac (1780). Their influence was savagely denounced in pamphlets during the Revolution.

JULES DE POLIGNAC (1780-1847), the 1st duc's second son, went from England back to France, with his elder brother ARMAND (1771-1847; later 2nd duc), to conspire against Napoleon in 1804, but they were arrested. Released in 1813, Jules was made a peer at the Bourbon Restoration (1815), but refused at first to take the constitutional oath as he thought it derogatory to the Holy See's rights. For this the Holy See granted him the Roman title of prince (1820; recognized in France 1822). His ultramontanism and extreme royalism appealed to Charles X (*q.v.*), who appointed him minister of foreign affairs on Aug. 8, 1829, and prime minister on Nov. 17. Responsible for the ordinances which provoked the July Revolution of 1830, he was arrested and, in December 1830, sentenced to life imprisonment. Released but banished in November 1836, he finally returned to France in 1845. The Bavarian monarchy in 1838 extended the title of prince to all his descendants, and as his elder brother died childless (March 2, 1847), he inherited the ducal title as well just before his own death on March 29. The comtes de Polignac descend from the 1st duc's third son, CAMILLE MELCHIOR HENRI (1781-1855). One of them, Comte PIERRE (1895-1964), was the father of Prince Rainier of Monaco.

Prince EDMOND MELCHIOR (1834-1901), fifth son of Jules, was a composer. In 1893 he married Winnaretta Singer (1865-1943), who, as Princesse Edmond de Polignac, was the outstanding Parisian patroness of *avant-garde* music in the first half of the 20th century.

POLIOMYELITIS (INFANTILE PARALYSIS) is an acute infectious disease caused by a filterable virus and characterized by symptoms that range from a mild nonparalytic infection to an extensive flaccid paralysis of voluntary muscles.

History.—There is evidence that the disease has existed for many centuries. However, the first clear description of poliomyelitis came from Jakob von Heine in 1840. It was not recognized in its epidemic form until Oskar Medin in 1887 reported observations on an outbreak in Sweden. In addition to the usual spinal form, he described the bulbar and certain less common types of the disease. C. S. Caverly, in 1896, recognized that the disease may occur in an abortive or nonparalytic form, a fact confirmed by others later.

While earlier outbreaks centred largely in Sweden, epidemics have occurred in many parts of the world and became particularly prominent in the United States after the beginning of the 20th century.

Incidence.—Severe epidemics have been reported in many countries and islands including North, Central and South America, Europe and Africa. The disease reached epidemic proportions in some region of the U.S. almost every year after the beginning of the 20th century until vaccine became available. The greatest recorded sustained incidence in the United States was in 1942-53; in 1950, for example, there were 33,344 cases in the U.S. In 1952 severe epidemics occurred in Denmark, Germany and Belgium. In Asia outbreaks have been reported in Bombay, Singapore, Japan, Korea and the Philippines.

Symptoms.—The commonest early complaints consist of mild headache, fever, sore throat, nausea, vomiting, diarrhea, restlessness and drowsiness. The temperature rises slowly, reaching its peak in two to three days, and then rapidly subsides. Fortunately more than two-thirds of the patients who develop these early symptoms recover and remain well without any signs of muscle weakness. When the disease is severer, the patient develops pain in the back and limbs, muscle tenderness, stiff neck, irritability and fretfulness.

Paralytic Forms.—*Spinal Poliomyelitis.*—This is the common-

est type of paralytic poliomyelitis and is caused by infection of the spinal cord. At about the third day of the illness, the patient develops weakness of the limbs. The paralysis may be of all grades of severity from transient weakness that soon disappears to complete and permanent paralysis. The lower limbs are more often affected than the upper limbs. Within a few months after the development of paralysis, the involved muscles begin to atrophy.

Respiratory Poliomyelitis.—The muscles of the chest that control breathing receive their nerve supply from the upper part of the spinal cord. When the virus injures this part of the spinal cord, the patient develops difficulty in breathing. Acts such as coughing, sneezing and sniffing cannot be carried out. When there is a definite loss of function to these muscles, it is essential that some mechanical device be used to aid respiration.

Bulbar Poliomyelitis.—That part of the nervous system situated just above the spinal cord is called the bulb or brain stem. In this region are situated the nerve centres that control swallowing and talking, and when poliomyelitis affects this area the patient has difficulty with these actions. Secretions collect in the throat. The voice becomes hoarse and develops a nasal twang. The accumulation of secretions in the throat may block the airway, causing the patient to suffocate. If this obstruction to the airway is not relieved, the patient loses consciousness and will die.

Diagnosis.—In the preparalytic stage of the disease, the diagnosis must depend on strong clinical suspicion supported by certain laboratory observations on the spinal fluid. This is particularly true of patients who become ill in the late summer and autumn in an area where poliomyelitis is prevalent. In 1951 a rapid method for identifying the infection became available, based on the direct inoculation of tissue cultures with stools of ill patients. Virus growth is manifested within 24 hours by a breakdown of the growing tissue culture cells.

Prognosis.—Of all patients who develop poliomyelitis, more than 80% recover within three to four days without the development of paralysis. When paralysis has occurred, considerable restoration of normal muscle powers may take place, although some residual weakness remains in almost half these patients. The over-all fatality rate in the United States was estimated in the 1960s at between 1% and 4%, while a death rate of 30% has been reported in Europe during periods of low prevalence.

Treatment.—Treatment during the preparalytic stages includes complete bed rest, isolation and careful observation. The patient should be permitted to assume whatever position he wishes. It is important to check carefully for evidence of limb paralysis or breathing or swallowing difficulty.

If paralysis occurs, good nursing care is of primary importance. The bed should be firm with a board under the mattress. Passive movement of the limbs can be used to avoid deformities. Moist heat usually makes the patient more comfortable. As muscle strength returns, exercises are increased. (See *Orthopedic Aspects*, below.)

When there is paralysis of the breathing muscles, some form of mechanical breathing aid is necessary. The one most commonly used is the tank respirator, or "iron lung." The patient is placed in the tank respirator with only his head emerging, and by a rhythmical increase and decrease of the pressure within the tank his chest is expanded and relaxed. In less severe cases it is possible to use a respirator that fits to the chest only (cuirass respirator) or a rocking bed.

When the patient develops difficulty in swallowing, with accumulation of secretions in the throat, it is important that the airway be kept open by removal of the secretions. This can be done by a mechanical suction machine. If suction of the machine is not adequate an artificial airway must be made from the outside into the throat (tracheotomy).

Etiology.—In 1909 Karl Landsteiner and Constantin Levaditi showed that the causal agent of poliomyelitis is a filterable virus. This virus cannot be cultivated on ordinary lifeless media since it grows only in media containing living tissue cells. It is fairly resistant to physical and chemical agents and is able to survive for some time in water, milk and sewage.

When the virus comes in contact with the defense mechanism

of the body it elicits the formation of specific antibodies that act to neutralize its infectivity. Of importance, however, is the fact that not all strains are antigenically or immunologically alike. Many strains have been isolated from patients with poliomyelitis from all parts of the world; they can be divided into three immunologically distinct types, and infection with one type does not protect against reinfection with one of the other types. The three types are known as type I, or Brunhilde; type II, or Lansing; and type III, or Leon.

Up to 1939 the virus could be transmitted to monkeys only. In that year, however, Charles Armstrong succeeded in transmitting the Lansing strain to eastern cotton rats and from these animals to white mice. In 1949 J. F. Enders and his associates demonstrated that the virus could be isolated and grown in tissue culture on nonnervous tissue cells, thus making it possible to study and grow this virus without the use of living animals. This inexpensive method of working with the virus greatly facilitated research and was directly responsible for the development of poliomyelitis vaccine.

Pathology.—The virus probably enters the body through the throat and intestinal tract, since large quantities are excreted in the stools for a number of weeks before and after an attack of poliomyelitis. The disease is probably spread from person to person by intimate human contact. It has been postulated that the virus migrates from the throat and intestines to the central nervous system along the peripheral nerves. However, more recent studies have suggested that the virus may spread from the alimentary tract into the blood and lymphatics, from whence it is disseminated widely throughout the body, including the nervous system. Within the central nervous system it spreads along nerve pathways (axonal transmission) and eventually reaches the more sensitive motor nerve cells in the spinal cord, medulla or brain. These are destroyed in varying numbers, and the destroyed cells are not replaced since nerve cells lack the power of regeneration. Not all cells attacked are destroyed, however, and those not severely injured recover their normal function in time. To the extent that they do recover a corresponding restoration of muscle function may be expected to take place.

Predisposing Factors.—Individual differences in the degree of natural susceptibility appear to exist. Many persons have acquired antibodies in their blood without having knowingly gone through a poliomyelitic infection. The disease commonly attacks those who seem to be in the best of health, so that undernutrition or faulty health do not appear to be predisposing factors.

It is generally held that a lasting immunity follows recovery from the disease. Second attacks are known to occur, however, some of which may be caused by strains differing immunologically from those that caused the first attack.

Among other predisposing factors, age has always been considered the most important. In early epidemics (*i.e.*, before *c.* 1945), most cases occurred in children under ten years of age. Later, however, there was a definite shift to the beginning of adult life.

Geographic areas appear to play little role in the disease. Although the majority of cases occur in temperate climates, the disease has a world-wide distribution and has been reported in the tropics as well as in Iceland and Alaska. Although the disease persists throughout the year, the highest incidence is in the late summer and early fall. Active cases may extend into early winter.

Strenuous exercise, sudden chilling and pregnancy all seem to predispose to the disease. It is generally accepted that removal of the tonsils at the time when the disease is prevalent predisposes to the severer forms of the disease. There is also suggestive evidence that injections of any type (vaccinations) may predispose to the disease, particularly when it is prevalent. (A. B. Br.)

Control.—Major interest regarding the control of this disease centred around the relative merits of the attenuated (live) oral poliovirus vaccine and the inactivated (Salk type) vaccine. The latter was employed throughout the world beginning in 1955 and it greatly reduced the incidence of paralytic poliomyelitis where used adequately.

An ultimate goal, however, has been elimination of epidemics of this disease and a further reduction of its sporadic incidence. To achieve this end, the oral type of vaccine began to be used in a number of countries in 1960, particularly in eastern Europe and Japan. Its manufacture was licensed in England in 1961 and in the U.S. in 1961–62.

Advantages of the oral poliovirus vaccine include its efficiency when given to the most susceptible age group, namely children of preschool age (six months to five years); its ease of administration; its ability to induce immunity very rapidly in the young child, a property that is particularly valuable in the face of epidemics; and finally its protection to a community, as well as to individual persons vaccinated, when used in community-wide programs or campaigns. It achieves this community protection by rendering the alimentary tract of those vaccinated resistant to reinfection by polioviruses, thus breaking the chain that allows the free spread of the virus and thereby preventing epidemics from spreading.

The most effective way of immunizing a population with the oral poliomyelitis vaccine is to employ it in a campaign in which the entire community participates. Such programs attempt to vaccinate as large a percentage of juveniles within a given geographical area as possible, the desirable goal being to give oral vaccine to a minimum of 80% of the local preschool and school children, particularly those who are five years of age and under. The most important age groups to be vaccinated are those under 18 and it is strongly advised that community-wide vaccination be conducted in winter rather than the summer months.

Subsequent to the community-wide vaccination campaign, continuing systems of vaccinating all the newcomers to the community should be maintained in order to protect all children brought into or born into the community after the campaign. For infants, this course of vaccination is usually integrated with other immunization procedures, such as those against diphtheria, whooping cough and tetanus. These are customarily started during the first year of life.

A complete course of vaccination with oral vaccine consists of the use of three separate types of oral vaccine, each of which represents a different attenuated strain of one of the three types of polioviruses. These three strains are given either individually or in various combinations.

With these two methods of control—the inactivated and attenuated vaccines, both of which have been shown to be effective in a slightly different way—it is likely that the incidence of poliomyelitis throughout the world may continue to be reduced. (See also VACCINE THERAPY.)

(J. R. PA.)

Orthopedic Aspects.—The orthopedic management of a paralytic patient is directed toward the prevention of deformities, correction of those that cannot be prevented and restoration of bodily function. Actually, 80% of patients with poliomyelitis require little more than general nursing care and recover without significant paralysis. Of the remaining 20%, not all require intensive orthopedic care. During the acute phase of the disease the patient must be kept at absolute bed rest. Attention is given to the prevention of joint contractures by proper positioning of the extremities. As long as the patient is bedridden care must be taken to prevent the development of decubitus ulcers (bedsores).

As muscle pain subsides active motion is begun. Frequently patients require assistance in certain movements to neutralize the opposing force of gravity. However, it is only through active contraction by the patient himself of the muscle groups still intact that sufficient strength can be restored to permit normal function of the part. In selected cases, supported walking or exercise in a water tank is of value. Other aids to the restoration of muscle power may occasionally be utilized. The relatively small group of patients who fail to regain enough muscle power to function independently can usually be taught to walk with the support of braces or crutches.

It is not until a permanent plateau of function is reached—usually 12 to 18 months after the acute illness—that surgical measures are considered. Surgery in poliomyelitis may be undertaken to (1) stabilize an unsupported joint; (2) correct fixed de-

formities; (3) adjust leg length inequalities; or (4) restore function. A common stabilizing procedure involves arthrodesis (fusion) of a joint. In such cases motion is sacrificed for position and strength. Extensive fusion is sometimes the treatment of choice in scoliosis (spinal curvature) resulting from postparalytic imbalance of the spinal musculature. Another useful type of surgical operation involves transplantation of one end of a functioning but expendable muscle in the region involved to a new insertion where its contraction will then produce a movement or perform a joint-stabilizing function formerly performed by a paralyzed muscle group. Leg length inequality, rarely considerable enough to require treatment, may, when necessary, be compensated for by a growth-arresting procedure on the uninvolved extremity at an age calculated to permit equalizing but not excessive growth of the shorter leg. Clearly the purpose of surgical treatment, whatever the type, is to restore the paralytic patient to as nearly normal function as possible and free him from the use of artificial supports.

POLISH LANGUAGE. Polish, the mother tongue of probably 30,000,000 speakers, belongs to the western group of the Slavonic (Slavic) languages (*q.v.*). Its first written records consist of proper names in Latin documents of the 12th century, and extant manuscripts containing any considerable amount of connected Polish text go back no earlier than the 14th century. The modern literary language may be dated from the 16th century, when the ferment of Reformation, Renaissance and Counter-Reformation produced the first outstanding Polish writers, such as Mikołaj Rej, Jan Kochanowski, Piotr Skarga and others associated with the Golden Age of Polish literature. Under their cultivation, Polish developed with astonishing rapidity into the refined instrument of literary expression that it has since remained.

Foreign influences on Polish have been numerous, but (except for the macaronic aberrations of the late 17th and early 18th centuries) have been easily absorbed without harm to the integrity of the language. The introduction of Christianity brought not only Latin, but also Czech, the language of the first missionaries, into living contact with Polish. As an already developed literary language, Czech continued to enjoy high prestige among the Poles as late as the 14th and 15th centuries, and there are still Polish words whose form betrays their Czech origin, such as *hańba* "disgrace," *brama* "gate," *władca* "to rule." The large medieval German immigration and settlement in Polish cities is reflected in an extensive layer of the vocabulary, such as *ratusz* "town hall," *burmistrz* "mayor," *malarz* "painter," *handel* "trade," *rachunek* "account," *gmach* "building," *szlachta* "nobility" and many others (compare German *Rathaus*, *Bürgermeister*, *Maler*, *Handel*, *Rechnung*, *Gemach*, *Geschlecht*). Italian (at the time of the Renaissance), French (in the 17th and 18th centuries) and English have supplemented the Polish vocabulary. In addition, special mention should be made of White Russian and Ukrainian influences, particularly as they penetrated into Polish through the works of writers from the eastern borderlands.

Polish shares with other West Slavonic languages a number of notable phonological characteristics, such as: (1) fixed stress ac-

cent—in Polish, on the penultimate syllable of the word; (2) non-palatization of Common Slavonic (CS) velars in forms like *kwiat*, *gwiazda*—compare Czech *květ*, *hvězda* and contrast Russian *cvet*, *zvezda*; (3) the development of CS *tj*, *dj* to hissing sounds, as in *świeca*, *miedza* (<CS **světja*, **medja*)—compare Low Sorbian *swěca*, *mjaza* and contrast Russian *svečá*, *mežá*; (4) *ś* (spelled *sz*) resulting from the second palatalization of CS *x*, as in *wszystek*, *wszak*—contrast the hissing sibilant in Russian *ves'*, *vsjákij*; (5) preservation of dental stops before *l*, as in *wiódt*, *mydło*—compare Czech *vedl*, *mýdlo* and contrast Russian *vël*, *mylo*.

More or less peculiar to Polish, particularly in contrast to Czech and Slovak, are such phenomena as: (1) nasal vowels (spelled *e*, *ę*), indirectly continuing the nasal vowels of CS, as in *mieśo*, *trzęść*—contrast Czech *maso*, *třásti*; (2) dispalatalization of CS *e*, *ě*, *ř* to *o*, *a*, *ar* before nonpalatalized *t*, *d*, *n*, *s*, *z*, *r* and *l* as in *zona*, *wiara*, *twardy*—contrast Czech *žena*, *vira*, *turdý*; (3) palatalization of consonants (indicated in the spelling by *i* following the consonant letter) before *e* from CS front *jer*—contrast, for example, Polish *pies*, *dzień* and Czech *pes*, *den*.

The dialects, whose differences cause no practical difficulties in understanding, are customarily grouped into a few major types, notably Great Polish and Pomeranian, Silesian, Little Polish and Mazovian. In addition, Cassubian has come to assume the role of a Polish dialect although, historically speaking, it is not. The dialect base of the literary language, which displays some features associated with Great Polish and others associated with Little Polish, is still a matter of dispute.

POLISH LITERATURE. Although Poland has been part of Christian Europe from the 10th century, Polish literature was slow to emerge as a distinct entity, partly because of Poland's geographical remoteness from cultural centres and the difficulties that assailed the young state, which was frequently attacked by plundering invaders and weakened by division into small principalities; and partly because of the domination of foreign priests, which resulted from the action of Mieszko I, prince of Poland, who, after accepting Christianity in 966, placed his lands in the hands of the pope. See **POLAND: History**.

THE MIDDLE AGES

Writings in Latin.—As in other European countries, Latin was at first the only literary language in Poland. Early writings in Latin included saints' lives and annals and chronicles written by monks and priests. An anonymous writer known as Gallus (probably a Benedictine monk from Provence) recorded the exploits of the Piast dynasty, and of Bolesław III Wrymouth in particular, to 1113 to a chronicle written in the style of the French epic *chansons de geste* (*q.v.*). Wincenty Kadłubek (1160–1223), a Polish bishop who had studied in Paris, wrote the *Chronica Polonorum* in the manner of an allegorical, devotional romance in an artificial and florid style. A chronicle known as the *Kronika*

Wielkopolska, probably written by a priest called Baszko, relates events up to 1271. The masterpiece among chronicles, however, is the *Annales seu Cronicae Incliti Regni Poloniae* (the *Historia polonica*) by Jan Długosz (q.v.; 1415–80), first printed (in part only) in 1615. It was the first, and, for centuries, the only, attempt at a systematic and scholarly history of medieval Poland. Długosz was also the author of a revision (publ. 1511) of one of two 13th-century accounts of the life of Stanisław of Szczepanów (see STANISŁAW, SAINT). The first history of Poland to be printed was the *Chronica polonorum*, by Maciej of Miechów (1457–1523).

The 15th century also produced the first lay writer, and the first official critic of the priesthood and the papacy, Jan Ostrobróg (c. 1436–1501), author of *Monumentum . . . pro Reipublicae ordinatione* (1475), a treatise attacking ecclesiastical power and urging reform of church and state. Stanisław Ciołek (1382?–1437) wrote court poetry modeled on that in other European countries.

Writings in Polish.—Use of the vernacular was at first allowed by the church only where Latin could not meet particular needs—in prayers, sermons, and songs, for instance. The oldest Polish literary text is a song in honour of the Virgin Mary, *Bogurodzica*, in which language and rhythm are used with high artistic craftsmanship. The earliest extant manuscript dates from 1407–08, but it was probably written much earlier.

Preaching in Polish became established toward the end of the 13th century. The oldest specimen of Polish prose, the *Kazania świętokrzyskie* ("Sermons of the Holy Cross"), dates from the end of the 13th or the beginning of the 14th century. Of the six surviving sermons, five are in fragmentary form only. *Kazania Gnieźnieńskie* ("Sermons of Gniezno"), another notable example of early Polish prose, dates from the late 14th century. The first extant translation of the psalms, the so-called *Psalterz królowej Jadwigi* ("Psalter of Queen Jadwiga") or *Psalterz Floriański* ("Florian's Psalter"), also dates from the end of the 14th century: the text is in Latin, German, and Polish, the Polish text being probably a copy of an earlier manuscript. Part of a translation of the Bible, made in 1455 by Jędrzej of Jaszowice for Queen Sofia, widow of Władysław II Jagiełło, has also survived. Lives and legends of the saints were also written in Polish during the 14th and 15th centuries.

Secular works began to appear toward the end of the 15th century. Satirical verse is represented by the *Pieśń o Wklefie* directed against the "Roman antichrist" (the pope) by Jędrzej Gałka, a follower of John Wycliffe and John Huss. A high literary standard was achieved in a morality verse dialogue, the satirical and grotesque *Rozmowa Polikarpa ze Śmiercią* ("Dialogue Between Master Polycarp and Death"). The style of the medieval period lasted late in Poland, and some of its characteristics continued well into the 16th century. Marcin Bielski (1495–1575) represented this late medievalism in his *Kronika wszystkiego świata* ("Chronicle of the World," 1551), the first general history in Polish.

Most of the surviving examples of medieval Polish literature long remained unknown, some major works being discovered only in the 19th century. But the complex technical organization of the best surviving examples implies a continuous literary tradition. Moreover, although its themes are those of the common European heritage, Polish writing of this period can be intensely personal within its anonymous framework. Devotional lyrics in particular, such as the fine *Żale Matki Boskiej pod krzyżem* ("Lament of the Mother of God Under the Cross") and the rich tradition of carols, reach a high level of poetic expression, and help to account for the rapid flowering of the language during the 16th century.

The groundwork for the leap into the ranks of major literatures was laid during the reign (1333–70) of Casimir III the Great (q.v.), who in 1364 founded the University of Cracow, and who promoted the entry of new ideas from west and south by his contacts with the courts of Hungary and Bohemia.

THE RENAISSANCE PERIOD

The Renaissance reached Poland comparatively late and lasted for a shorter time than in other countries. It flourished abun-

dantly, however, and is called the "golden age" of Polish literature. Several factors, such as external security, constitutional consolidation, and the ferment of the Reformation, contributed to this flowering; and the rapid development of printing in the early years of the 16th century facilitated the stabilization of spelling. The first permanent press was established at Cracow by Jan Haller at the turn of the 15th century, and the first book to be printed entirely in Polish, the devotional *Raj duszny* ("The Soul's Paradise") by Biernat of Lublin, was issued c. 1513. The modern literary language dates from this time.

The first generation of writers influenced by the Italian Humanist movement wrote in Latin. Among them were Jan Flachsbander (Joannes Dantiscus; 1485–1548), a courtier, diplomat, and author of incidental verse, love poetry, and panegyric; Andrzej Krzycki (Cricius; 1482–1537), the archbishop and primate, who wrote witty and frivolous epigrams, courtly panegyrics, political verse, and sincere religious poems; and Klemens of Januszkowo (Janicki,

Janicius; 1516–43), a peasant by birth, who studied at Padua and became poet laureate and the first original Polish poet. His elegies in the manner of Tibullus and Ovid bear the stamp of his emotional, melancholy personality.

A writer who combined medieval and Renaissance aspects was Mikolaj Rej of Nagłowice (1505–69). A self-educated man of great vitality and outstanding literary force, he was the first idiomatically Polish talent and the first widely read writer of his time; and he is known as "the father of Polish literature." His numerous works in verse include a large collection of satirical epigrams, *Figliki* ("Trifles," 1574),

but more important are his prose works, especially *Postilla* (1557), a collection of Calvinist sermons; and the *Zywot człowieka pociwiewego* ("Life of an Honorable Man," 1558), a description of the life of an ideal nobleman, which contains a unique account of customs and conditions in 16th-century Poland. It forms one section of *Zwierciadło* (1568), a larger work modeled on the medieval speculum. Rej's verse *Krótką rozmową między panem, wójtem i plebanem* ("Short Debate Between the Landlord, the Bailiff, and the Vicar," 1543) treats topical themes in a medieval manner and is the only Polish example of the medieval dialogue form.

The second generation of Humanist poets, and indeed the whole Renaissance period, is dominated by the personality of Jan Kochanowski (1530–84). The son of a country squire, he studied in Padua and Paris and was encouraged to write in the vernacular by the example of Pierre de Ronsard. He was the first Polish writer to attempt heroic satirical poetry and classical tragedy (in *Odprawa posłów greckich*, 1578; Eng. trans. *The Dismissal of the Greek Envoys*, 1918, on a subject taken from the *Iliad*). His lyrical works, however, surpass these experiments. His adaptation of the Book of Psalms, *Psalterz Dawidów* (1578), illustrates his mastery of form and metrical versatility; and his *Fraszki* ("Trifles," 1584) are typical of the Renaissance in their vigorous

joy of life and epigrammatic precision. The collection *Pieśni* (1586; Eng. trans. *Chants*, 1932) includes love songs, patriotic and festive songs, and reflective lyrics, often revealing a Horatian attitude to life. His crowning achievement, the first Polish work to equal the great poems of western Europe, is his *Treny* (1580; Eng. trans. *Lamentis*, 1920), inspired by his despair after the death in 1579 of his infant daughter, Ursula, and his final recovery of spiritual harmony. In Kochanowski's poetry, the archaisms still apparent in Rej's work have almost disappeared: language and idiom are modern. The flexibility and assurance of his poetic genius was recognized at once as a sign that the Polish literary language had attained its maturity; his diction remains a model of harmony and purity.

The most notable of Kochanowski's followers was Szymon Szymonowicz (Simonides; 1558–1629). A burgher of Lwów (Lvov), educated at Cracow and abroad, in his *Sielanki* ("Eclogues," 1614) he introduced to Poland a poetic genre which was to retain its vitality until the end of the 19th century. These pastoral idylls, influenced by both Theocritus and Virgil, exemplify the processes of imitation, adaptation, and assimilation by which Renaissance writers brought foreign models into the native tradition.

The numerous poems, in Latin and Polish, of Sebastian Klonowicz (1545–1602) are of interest for their detailed description of contemporary life. In the Latin poem *Roxolania* (1584), he gives the first complete account of the geography, landscape, and people of Ruthenia; and in *Flis* (1595) he vividly describes the valley of the Vistula and the life and customs of the raftsmen. *Worek Judaszów* ("Judas' Sack," 1600) is a satirical and didactic poem on the life, especially the folly and vice, of Lublin, of which he was mayor.

The prose of the 16th century ranks with its poetry in vitality and range. The most eminent prose writer in Latin was Andrzej Frycz Modrzewski (1503–72). In his *Commentariorum de re publica emendanda libri quinque* (incomplete 1551; complete ed. 1557) he evolved a bold social and political system extending far beyond the accepted ideas of his time, based on the principle of the equality of men before God and the law. Another notable writer in Latin was Marcin Kromer (1512–89), scholar, humanist, historian, and Catholic apologist, who studied in Italy, Germany, and France. His *Polonia sive de origine et rebus gestis polonorum* (1555) and *Polonia sive de situ, populis, moribus, magistratibus et Republica Polonici* (1577) are important for their detailed account of Polish history, geography, institutions, people, and customs, and for their elegant style. Of his theological and controversial works, the most interesting is the Polish *Rozmowy dworzanina z mnichem*, a defense of Catholicism in dialogue form. Other outstanding prose writers were Stanisław Orzechowski (Orichovius; 1513–66), Łukasz Górnicki (1527–1603), and Piotr Skarga (Powęski; 1536–1612). Orzechowski, who wrote in Latin and Polish, was a controversialist who commanded a keen and artistically sure range of expression for a great diversity of intellectual attitudes. Górnicki, in *Dworzanin polski* ("The Polish Courtier," 1566), his free version of Baldassare Castiglione's *Il Cortegiano* (which he transplanted to Polish soil and adapted to Polish conditions), created in aristocratic prose the ideal of Renaissance manhood. Skarga, a militant Jesuit and the first representative of the Counter-Reformation in Poland, wrote the enormously popular *Żywoty świętych* ("Lives of the Saints," 1579) and the famous political treatises *Kazania sejmowe* ("Parliamentary Sermons," 1597). Cast in the form of sermons addressed to the assembled diet, these advocate curtailment of parliamentary rights and a strengthening of royal authority in the national interest.

The 16th century produced a great wealth of historical writings, though none to compare with those of Długosz. It also saw the beginnings of polemical writing, much of it inspired by the rise of Socinianism (see SOCINUS; UNITARIANISM). Socinian writers, as well as engaging in polemic, produced notable works, in Latin and Polish, on social, moral, and religious problems. After the expulsion of the Polish Brethren from Poland many of them settled in Amsterdam, where they published the *Bibliotheca Fratrum Polonorum* (1656), which exerted some influence on the political thought of Spinoza and Locke.

Many translations of the Bible were published. The Catholic translation (*Nowy Testament*, 1593; complete Bible, 1599) by Jakub Wujek (1540–97) came to occupy in Poland a position comparable to that of the Authorized (King James) Version (1611) in England and is an outstanding literary work.

In this period Polish literature became a national literature expressing a fully awakened national consciousness, the ethos of a people. It reflected Poland's position as a great power with far-flung boundaries, the evolution of the nobility as a ruling class, and the country's economic prosperity. Its influence spread to countries east of the Polish border, above all to Moscow; Rej's *Postilla*, for example, was translated into Russian and Lithuanian. To the west the culture of the Polish Renaissance was represented by men of such high repute as Copernicus (q.v.).

THE BAROQUE PERIOD

The Baroque period began very early in Poland, almost at the same time as in Italy. In 1564 Poland accepted the resolutions of the Council of Trent and invited the Jesuits to settle in the country, and from about 1570 Protestant influence began to wane. The Baroque style and outlook were congenial to the Polish spirit; this period was one of considerable literary output, in spite of almost incessant wars. Indeed perhaps it mirrored, in its stylistic tension, the external strife characterizing the 17th century.

A forerunner of Baroque poetry was Mikołaj Sep-Szarzyński (1550–81), who, dying in his prime, left only one volume, *Rytmy* . . . (1601), containing predominantly religious poetry akin to that of the English metaphysical poets. The Baroque period itself had a preference for satire and the pastoral. Foremost among satirists was Krzysztof Opaliński (1610–56), prince palatine of Poznań. His *Satyry* . . . (1650), modeled on those of Juvenal, are bitter, pessimistic, and wide-ranging in their attack. The pastoral is represented by Samuel Twardowski (1600–60), author of the pastoral epic *Daphnis* . . . (1638), and of the romance *Nadobna* ("Enchanting") *Pasqualina* (1655), a paradoxical tale of sacred and profane love in which the Polish Baroque style achieves perhaps its most finely wrought splendour. The collection of love songs with a Ruthenian setting entitled *Roksolanki* (1654) represents a further achievement in lyric poetry. They were long attributed to the poet Szymon Zimorowicz (1608–29), but are now known to have been written by his brother, Bartłomiej Józef (1597–1677) who also, in *Sielanki* ("Pastorals," 1663), introduced strikingly original, dramatic elements of topical reference, often with macabre effect, into the traditional form of the pastoral idyll, superimposing images of war and death upon the pastoral background with typical Baroque incongruity.

A parallel but less formalized rustic genre produced much verse celebrating rural life, generally of a somewhat low poetic power. One of the more successful examples is the *Votum* by Zbigniew Morsztyn (c. 1627–90?), whose finest achievement, however, is in religious poetry inspired by the ideas of the Arian sect. His *Emblemata* (first complete ed. 1954) are the only known examples of the emblem tradition in Polish literature. In contrast with his sobriety is the work of his cousin, Jan Andrzej Morsztyn (c. 1613–93), whose language is marked by the extravagant "conceited" style of the Italian *Seicento*. The formal complexity and skill of his verse, most of it unpublished until the 19th century, is unsurpassed; and his translation (1661) of Corneille's *Le Cid* remains the standard Polish version. The Jesuit Maciej Kazimierz Sarbiewski (Sarbivius; 1595–1640) was internationally celebrated for his Latin poems. His *Lycorum libri* (1625) went through 36 contemporary editions.

The age was characterized by the ambition to write heroic epics—a preoccupation which can be explained by current historical events: wars with Sweden, Russia, and Turkey, internal revolts, and attempts to introduce constitutional reforms. The *Pharsalia* of Lucan attracted both translators and adapters. Torquato Tasso's *Gerusalemme liberata*, brilliantly translated by Piotr Kochanowski (1566–1620), inspired attempts at the writing of epics on national themes. Among the more notable is the vigorous *Wojna chocimska* ("The War of Chocim," written 1673; publ. 1850), describing the Turkish onslaught through Moldavia in 1621,

by Wacław Potocki (1625–96). Potocki was a prolific poet more famous for his epigrams, collected in *Ogród Fraszek* ("Garden of Rhymes," written 1670–95; publ. 1907), which give a lively picture of contemporary ideas and manners. Another epic, the *Psalmodia polska* (1695), by the poet and historian Wespazjan Kochowski (1633–1700), was written under the impact of John III Sobieski's victory over the Turks at Vienna in 1683, at which Kochowski himself was present; the work is interesting both for its style, based on biblical parallelism, and as the first example of a theme developed by writers of the Polish Romantic movement—the messianic interpretation of Poland's destiny.

The prose of the period does not rise to the level of its poetry or to that of Renaissance prose. It was notable, however, for its wealth of diaries and memoirs. Outstanding are the memoirs (*Pamiętniki*; publ. 1836) of Jan Chryzostom Pasek (c. 1630–1701), a country squire and soldier. These are written in a lively, humorous style, and give a vivid description of the life of a man of independent personality. Other notable prose writers were Stanisław Żółkiewski (1547–1620), author of an impressively direct account of the campaign against Moscow (*Początek i progres wojny moskiewskiej*); Andrzej Maksymilian Fredro (1620–79), writer of skeptical aphorisms (*Przysłowia* . . . ["Proverbs . . ."], 1658); Stanisław Herakliusz Lubomirski (?1636–1702), notable for his political treatises; and Łukasz Opaliński (1612–62), author of polemical literature. The last three wrote in both Polish and Latin.

The period was also notable for the emergence of the letter as a literary form. The letters of John III Sobieski to his wife are remarkable for their passion and tenderness, and for their day-by-day account of his experiences of battles and diplomacy. Their style combines elegant ease with sincere feeling, and they are among the best letters in the language.

Another interesting development was the rise of a popular anonymous literature, exemplified by the so-called "*komedia rybaltowska*" ("ribald comedies").

The last stage of Baroque literature, from c. 1675 to c. 1750, and from 1697 called the "Saxon period" because of the accession to the throne, as Augustus II, of the elector of Saxony, displays a long process of decline. This period is marked only by the emergence of the first women writers (e.g., Elżbieta Drużbacka, 1695–1765, author of popular romances and moral and religious verse) and by the important figure of Stanisław Konarski (q.v.; 1700–73), a reformer of education, literature, and the decadent political system. Konarski wrote poetry in Latin (*Opera lyrica*, 1767); a tragedy, in the classical French style, in Polish (publ. 1880); and political treatises in clear, incisive prose.

It was not until the mid-20th century that the literature of the Baroque period was fully appreciated. With all its contradictions, it produced an abundance of works and made an original contribution to European Baroque. It might well be regarded as the most enduring of all Polish styles, for many of its features recur in Romantic and modern writing.

THE ENLIGHTENMENT

Close contact with western Europe, especially with France and, to a lesser extent, with England, characterized Polish literature of the Enlightenment period. Certain general ideas and tendencies of the second half of the 18th century coincided with Poland's political situation. The country, exhausted by wars and burdened with a corrupt political system, was menaced by aggressive neighbours (see POLAND: *History: The Elective Kings*). Polish literature was imbued with a desire to improve and reform, to strengthen the state against collapse, or, at least, to save the country's national culture from the effects of partition and foreign rule. Literary developments included the rise of drama; the introduction of the periodical and the novel; the publication of the first Polish dictionary; the application to historical writing of scholarly methods; and, in poetry, the introduction of *dumy* (ballads), which were to be further developed in the Romantic period.

Drama.—Drama was established late in Poland, although Rej, Kochanowski, and Szymonowicz had attempted playwriting, and

didactic plays were performed in the Jesuit colleges throughout the 17th century (see DRAMA: *Modern Drama: Jesuit School-Drama*). The earliest significant event was the inauguration of the national theatre in Warsaw in 1765, on the initiative of the last king of Poland, Stanisław II Poniatowski, a patron of literature and the arts. The three principal dramatists (much influenced by French models) were Franciszek Bohomolec (1720–84), Wojciech Bogusławski (1757–1829), and Franciszek Zabłocki (1750–1821). Bohomolec, in his adaptations of Molière's plays, satirized the ignorance and folly of the Polish aristocracy. Bogusławski wrote plays adapted from foreign originals and the popular national comic opera *Krakowiacy i Górale* ("Cracovians and Mountaineers," 1794), based on Polish folklore. In 1783 he became director

BY COURTESY OF POLSKA AKADEMIA NAUK, INSTYTUT SZTUKI

ALEKSANDER FREDRO, AN 1828 LITHOGRAPH AFTER THE DRAWING BY A. LAUB. IN THE POLSKA AKADEMIA NAUK, INSTYTUT SZTUKI

of the national theatre and after the partitions toured the country with a traveling company. Zabłocki, a prolific playwright, produced at least two works of lasting value: *Fircyk w załotach* ("The Dandy's Courtship," 1781) and *Sarmatyzm* (1785), the latter introducing the "foray" theme developed by Adam Mickiewicz (q.v.) in his *Pan Tadeusz* The comedies of Aleksander Fredro (1793–1876) appeared when the Polish Romantic movement was already under way and in them the influences of Molière and Carlo Goldoni are assimilated to the native idiom (e.g., *Zemsta* ["The Revenge"], 1834). They are remarkable for their brilliant "type" characteri-

zation, ingenious construction, and great metrical facility. (See also DRAMA: *Modern Drama: The Late 18th Century*.)

Prose.—Didacticism permeated most of the prose writing of the period. The first modern periodicals appeared (e.g., the *Monitor*, 1765–85, modeled on the English *Tatler* and *Spectator*). Several men of great intellectual gifts wrote on contemporary issues. Among them were Stanisław Staszic (1755–1826), who, in *Przestrogi dla Polski* ("Warning to Poland," 1790), presented a grim picture of the country's social and economic depredation; and the statesman, Hugo Kołłątaj (q.v.; 1750–1812), whose style in his political treatises is distinguished by forcefulness and clarity.

From the spirit of the Enlightenment and its educational and social reforms sprouted a new, widespread cultural movement typified by the compilation of the first dictionary of the Polish language (*Słownik języka polskiego*, six volumes, 1807–14) by Samuel Bogumił Linde (1771–1847).

Poetry.—The first poet of the Enlightenment period was the bishop Adam Naruszewicz (1753–96). His poetic works—fables, satires, pastorals—considered chronologically, reflect the transition from the Baroque to the Classical styles. He also wrote, in prose, the first history of Poland making use of modern methods of scholarship—the *Historia narodu polskiego* (seven volumes, 1780–86), recording events to the end of the 14th century. The central poet of the period was Count Ignacy Krasicki (1735–1801), prince-bishop of Warmia (Ermeland), and a man of European outlook and modern, skeptical, intellect. His diverse writings include two mock heroic poems, *Myseis* (1775) and *Monachomachia* (1778); *Satyry* (1779); and the *Bajki i przypowieści* ("Fables and Moral Tales," 1779). They are remarkable for their concise expression, formal elegance, and wit. Krasicki also introduced the novel to Poland with *Mikołaja Doświadczyńskiego przypadki* ("The Adventures of Mikołaj Doświadczyński," 1776), which shows the influence of Swift and Rousseau.

Lyrical poetry continued to develop. Two writers are outstanding: Franciszek Karpiński (1741–1825), who continued and developed features of the Baroque style in his enormously popular pastorals and religious songs; and Franciszek Dyonizy Kniaźnin (1750–1807), a conscious experimenter, who rewrote much of his

earlier work to achieve stylistic uniformity. His verse, generally cool and intellectual in quality, anticipated certain Romantic themes and preoccupations, such as folk poetry, popular superstition, and gypsy life.

The personality of Julian Ursyn Niemcewicz (q.v.; 1757?–1841), whose writings were inspired by patriotism and concern for social and political reform, bridges the gap between the eras before and after the partitions of Poland. He was the first Polish writer thoroughly acquainted with English literature. His early translations of English Romantic ballads influenced Mickiewicz, and his own original *dumy* were the first of their kind in Poland. He also introduced the historical novel to Poland, with *Jan z Tęczyny* (three volumes, 1825), which shows the influence of Sir Walter Scott. His effective comedy, *Powrót posła* ("The Envoy's Return," 1790), written during a recess of the four-year diet to propagate the cause of the Reform Party, was immediately successful and is one of the best dramatic works of the period.

After the loss of national independence resulting from the last of the three partitions of Poland in 1795–96, the tradition of patriotic poetry was continued by the *émigré* soldier-poets who belonged to the Polish legions of Napoleon's army under the leadership of Gen. Jan Henryk Dąbrowski (Dombrowski). Among them was Józef Wybicki (1747–1822), author of the immensely popular patriotic song *Mazurek Dąbrowskiego* (written in Italy in 1797), beginning *Jeszcze Polska nie zginęła* . . . ("Poland has not died yet . . ."), which in 1918 was adopted as the Polish national anthem.

A second, distinct period of Polish classicism, less rewarding than the first, and called pseudoclassicism, covers the years of the duchy of Warsaw (created by Napoleon in 1807–09) and the Congress kingdom, under Russian rule, established by the Congress of Vienna. In general the writing it produced, constricted by its own rigid canons of taste, lacks freshness. Taken as a whole, however, the literature of the Enlightenment period reestablished a close contact with the West, and also became the mouthpiece of national consciousness. Although it was a literature of a community undergoing a severe political crisis, it exercised an unmistakable influence on neighbouring countries; Krasicki, especially, influenced Russian, Czech, and even Rumanian writers.

ROMANTICISM

The Romantic period began later in Poland than in England or Germany, but it lasted longer than in any other country, and is generally regarded as the greatest period in Polish literature. The rise of Romanticism coincided with a tragic moment in Polish history—the loss of independence resulting from partition—and the great writers of the period found in Romanticism an expression of their own mood. Their writings are imbued with a prophetic quality, and express Romantic despair and aspiration with grandeur of conception and execution. The need to interpret their country's destiny gave to the work of the three great poets of the Romantic movement—Adam Mickiewicz (q.v.; 1798–1855), Juliusz Słowacki (q.v.; 1809–49), and Zygmunt Krasiński (1812–59)—unusual visionary power and moral authority, and they were regarded as national bards, apostles of the movement for national freedom. Writing in exile, they kept alive their country's faith in the ultimate restoration of Polish independence, and their concern with political and historical problems gave the literature of the Polish Romantic movement its unusual strength and spiritual passion.

Writers in Exile.—Mickiewicz is regarded both as the greatest Polish poet and as the leader of the Romantic movement, and the publication of his *Poezye* (two volumes, 1822–23) was the first major literary event

of the period. The first volume, containing ballads and romances, begins with an important preface explaining his admiration for these western European forms and his desire to transplant them to Polish soil. In volume II were included parts II and IV of his *Dziady*, in which he combined folklore and mystic patriotism to create a new kind of Romantic drama. Mickiewicz' greatest works, however, were written after 1824, when he was deported to Russia for his revolutionary activities as a student: they include the *Sonetów Krymskie* ("Crimean Sonnets," 1826); the visionary third part of *Dziady* (1833); the messianic interpretation of Poland's past and future destiny written in a biblical prose, *Księgi narodu i pielgrzymstwa polskiego* (1832; *Books of the Polish Nation and its Pilgrimage*, 1925); and the great poetic epic, *Pan Tadeusz* . . . (1834; Eng. trans. 1962).

The suppression of the insurrection of 1830–31 drove the cultural elite of Poland into exile in France: among the poets whom Mickiewicz joined there were Słowacki, Krasiński, and Cyprian

Norwid. Słowacki, a Romantic in the fullest sense, who in all his work shows poetic genius, wrote verse-narratives in the style of Byron (the most outstanding being *Beniowski*, 1841) as well as accomplished lyric poetry. Like Mickiewicz, though in a very different style, he was inspired by patriotic themes: his *Kordian* (1834), a drama of conspiracy and the problems of commitment, is the counterpart of Mickiewicz' *Dziady*; and *Anielli* (1838) was inspired by the *Books of the Polish Nation*. . . Słowacki imbued traditional forms with new aesthetic content. *W Szwajcarii* (1839; Eng. trans. *In Switzerland*, 1953) is a transformed pastoral, exalted to an unprecedented degree of subtlety, and probably the finest lyrical work in the Polish language. Much of his work is in dramatic form, and although it was not intended for production, and he lacked experience of the stage, it laid the foundations of Polish tragic drama. His plays show the influence of French Romantic drama (*Maria Stuart*, 1833; *Mazepa*, 1840); Shakespeare (*Balladyna*, 1839; *Horsztyński*, publ. 1909); classical tragedy (*Lilla Weneda*, 1840), a symbolic drama of Polish legendary history; and Calderón (*Księż niezłomny*, 1844, a creative adaptation of *El Principe constante*). The last years of Słowacki's life were devoted to writing the unfinished *Król-Duch* ("The Spirit King," 1849), a lyrical and symbolic epic describing the history of a people as a series of incarnations of the spirit of the nation.

Zygmunt Krasiński, when only 23 years of age, published (anonymously, as all his works) *Nieboska komedia* (1835; Eng. trans. *The Undivine Comedy*, 1924). This play presented, for the first time in Europe, the struggle between two social classes, and the opposed worlds and cultures of the aristocracy and the disinherited masses, which share the common characteristic of spiritual despotism. *Irydion* (1836; Eng. trans. 1927), his second play, is an allegory of Poland's fate, presented as a conflict between the Greeks and the Romans. In *Przedświt* ("The Moment Before Dawn," 1843), he developed the messianic interpretation of Polish history, foreshadowed by Kochowski's *Psalmodya polska*

(see above), and this conception of Poland as "the Christ among the nations" is also expounded in *Psalm przyszłości* ("Psalms of the Future," 1845). The intrusion of fantastic or supernatural elements into a realistic setting is characteristic of many Polish Romantic works, facilitating a type of symbolic expression which established itself firmly in the Polish literary tradition.

The genius of Cyprian Kamil Norwid (q.v.; 1821-83) was not fully recognized until the 20th century. He belonged to the second generation of post-1830 poets, and he became one of the most tragic figures among them. During his lifetime he was misjudged and obscure. This lack of recognition resulted from the duality of his attitude (he accepted some of the Romantic ideas while sharply criticizing others), but even more from his ironic intellectual reserve, which enabled him to distinguish between false and genuine ideological coinage too acutely for the comfort of his contemporaries. Few of his works were published during his lifetime, a notable exception being the verse dialogue on aesthetics, *Promethidion* (1851), which expounds a theory of the social and moral function of art anticipating that of John Ruskin (q.v.). The authentic text of his most important lyrical collection, the *Vademecum*, was first published in 1947 (new, complete ed. 1962). He experimented with free verse and the rhythms of natural speech, and foreshadowed the French Symbolists in his analogical method of presenting the poetic concept.

The lesser *émigré* talents of Romanticism formed the so-called Ukrainian School. The most outstanding of the Ukrainian poets was Antoni Malczewski (1793-1826), author of a single poem, the Romantic verse-narrative *Maria* . . . (1825; Eng. trans. 1935), a Byronic tale of love and treachery with a Ukrainian setting, remarkable for its originality of diction, its dramatic tension, and its unity of mood. Other members of the group were the radical conspirator Seweryn Goszczyński (1801-76), who was also influenced by Byron; and Józef Bohdan Zaleski (1802-86), author of naïvely stylized folk songs.

There were fewer writers of prose than poets among the exiles. Among the novelists, mention should be made of Zygmunt Miłkowski (pseudonym Teodor Tomasz Jeż; 1824-1915), a writer on a wide range of subjects including folklore and the history of the Balkan countries. The literary criticism of Maurycy Mochacki (1804-34), a passionate advocate of Romanticism and the first Polish critic to define the part to be played by literature in the spiritual and political life of society, and to link literature with Poland's political progress, exercised a strong and not wholly beneficial influence on literary theory during the following decades. The immense history of Poland by the scholar and patriot Joachim Lelewel (q.v.; 1786-1861), is an impressive example of the prose of the period.

Writers in Poland.—As a result of partition, Romantic poetry in Poland was limited to closed provincial circles. In Warsaw a group of young, exuberant poets called the "Warsaw Bohème" was formed, but its activities were restricted by political pressure. The most fully developed talent in this group was that of Teofil Lenartowicz (1822-93), who sang the praise of the countryside and peasantry of central Poland. In Poznań, under Prussian domination, Ryszard Wincenty Berwiński (1819-79) made a meteoric appearance as a poet of social radicalism (*Poezje*, two series, 1844). His prose *Studia o literaturze ludowej* ("Studies on Folk Literature," 1854) marks a step away from Romantic nationalist interpretations of folk literature, and stresses the international community of folk tradition.

Among other provincial poets in Poland were Kornel Ujejski (1823-97), a native of Galician Podolia, whose *Z dymem pożarów* ("With the Smoke of Fires"), written after the Galician massacre in 1846, became the national anthem of Austrian Poland; Wincenty Pol (1807-72), also a Galician, who wrote unsophisticated and effective songs about the events of the 1830-31 rising which captured the hearts of the people and were praised for their directness and vigour by Mickiewicz; and Ludwik Kondratowicz (pseudonym Władysław Syrokomla; 1823-62), a Lithuanian, who described episodes from rural life in *gauwėdas* (verse tales in a conversational style), and was at his best in the shorter tales, bitterly satirizing the sadness and hardships of peasant life.

Prose was more popular with writers in Poland than with those in exile. Henryk Rzewuski (1791-1866), a genuine artist, belonged spiritually to the 18th century. His *Pamiętki Seweryna Soplicy* ("Memoirs of Seweryn Soplica," 1839), a series of discursive narratives on 18th-century themes, evokes the atmosphere of the Baroque tradition. Toward the end of the period the first signs of a realistic tendency are discernible in the work of Józef Korzeniowski (1797-1863), particularly in the novels *Spekulant* (1846) and *Kolokacja* (1847), portraying the life of the impoverished gentry in a remote countryside. The woman novelist Narcyza Żmichowska (pseudonym Gabryella; 1819-76) produced the strange *Poganka* ("The Pagan," 1846, revised 1861), a tale of a man demoniacally possessed by an ideal love which finally destroys him. A kind of psychological allegory, it anticipates 20th-century sensibility in its subtle analysis of feeling.

The dominant figure among the prose writers of the period was Józef Ignacy Kraszewski (q.v.; 1812-87), a giant of literary prolificacy whose output runs into hundreds of volumes of fiction, history, ethnography, criticism, etc. His imaginative writings reflect the change of literary styles over the long period of his career. Banished to Dresden by the Russian authorities in 1863, he continued to exercise a considerable influence on Polish writers at home and in exile, maintaining the Polish cause, both in politics and letters, by his manifold contracts and activities.

The Influence of Romanticism.—Polish Romanticism, conscious of its role as the torch of the national spirit, exerted a profound influence, and retained its force as a mode of thinking beyond the period of the political circumstances which fostered it. It produced works of the highest artistic value, which excited the interest of foreign writers. Mickiewicz, for example, exerted considerable influence on H. F. de Lamennais (q.v.), and on the Slavonic literatures; and was compared by George Sand with Goethe and Byron. Słowacki's poetic technique proved of fundamental importance to writers at the end of the 19th century, and that of Norwid was increasingly felt in the mid-20th century. The artistic achievements of the period therefore stood the test of time, though the political implications of the Romantic movement led to the disastrous insurrection of 1863, which ended in the absorption of Poland as a province of Russia.

POSITIVISM

The literature of the period following the 1863 uprising is called "positivism," and reflects the mood of practical thinking and action, and the rationalist reaction against Romanticism and the domination of life by literary theory. Politically, the positivist mood led to renunciation of armed resistance and to the concentration of energy on retrenchment, the preservation of the ideological and cultural assets of the nation, and the development of material prosperity. The rise in Russian Poland of a new urban intelligentsia, formed from the impoverished members of the gentry who moved to the towns after the emancipation of the peasants in 1864, acted as the leaven in this ferment. Popular journals and periodicals were of particular importance in the dissemination of new ideas, especially the widely read *Tygodnik Ilustrowany* (founded 1859).

The natural consequence of the positivist outlook was the predominance of prose, particularly journalistic prose, over poetry. With other writers of the Warsaw School, of which he was the leader, Aleksander Świętochowski (1849-1938) voiced democratic anti-clerical and anti-aristocratic views in his weekly newspaper *Prawda* (1881-1901), and in his novels, plays, and short stories. Bolesław Prus (pseudonym of Aleksander Głowacki; 1847-1912), a journalist with firsthand experience of proletarian conditions, ranks high among Polish short-story writers and is one of the most considerable Polish novelists. His *Lalka* ("The Doll," 1890) gives a complex picture of bourgeois life in Warsaw toward the end of the 19th century; and *Faraon* (1897; Eng. trans. *The Pharaoh and the Priest*, 1902) is an ambitious evocation of ancient Egypt with a curiously equivocal approach to the theme of power. Eliza Orzeszkowa (q.v.; 1841-1910), a campaigner for social reform, wrote novels on the emancipation of women, the ignorance and superstition of the peasants, and the Jewish problem; and, in her

outstanding three-volume epic, *Nad Niemnem* ("By the Niemen," 1889), gave a realistic description of the life of the Polish gentry. In this, and in books on less topical subjects (e.g., *Cham* ["The Boor"], 1888), she shows considerable psychological penetration and a fine sense of style. Another popular novelist, and winner of the Nobel Prize for Literature in 1905, was Henryk Sienkiewicz (q.v.; 1846–1916). His early critical works propounded positivist aesthetic theories, and that he was aware of the social function of art is clear from his statement that his historical trilogy (1884–88) was written "to fortify the hearts" of his countrymen, but in choice of subject and style he is not typical of his period. His early short stories, however, show acute awareness of the contemporary situation and stark realism.

A more flexible naturalism began to gain ground toward the end of the period. The transition is to be seen in the novels and short stories of Adolf Dygasiński (1839–1902), famous for his realistic but sympathetic portrayals of animal life (e.g., the novel *Zając* ["The Hare"], 1900), which are to be compared with those of Rudyard Kipling. A notable personality of the later part of the period was Gabriela Zapolska (1860–1921), an outstanding critic of social hypocrisy in her naturalistic novels and lively comedies. Trained as an actress, she excels in writing dialogue and in power to present dramatic situations in such plays as *Moralność Pani Dulskiej* ("The Morals of Mrs. Dulska," 1907).

SOVFOTO

GABRIELA ZAPOLSKA

The period produced only two poets of importance: Adam Asnyk (1838–97), a reflective lyricist of formal dexterity but limited imaginative range; and Maria Konopnicka (née Wasilowska; 1842–1910), the prolific author of sentimental verses on the underprivileged. Some of her less characteristic work (e.g., the cycle *Italia*, 1901) has distinction.

THE "YOUNG POLAND" MOVEMENT

The "Young Poland" movement was similar to contemporary trends in other western European countries. The name is used to describe several different groups and tendencies united only by their opposition to positivism. The movement was dominated by a return to the literary expression of feeling and the imagination, and from this acquired its other name of neoromanticism. In aiming to free the arts from utilitarianism, it showed affinities with the French Symbolists, and with certain aspects of French naturalism. Among the movement's pioneers were the poet Antoni Lange (1861–1929) and Zenon Przesmycki (Miriam; 1861–1944), editor of the important Symbolist review *Chimera* (1901–07), who helped to reestablish a closer contact between Polish and foreign literature, particularly poetry. Both made translations from various languages; both expressed their aesthetic theories in critical essays. Przesmycki's most influential contribution to the development of modern literature, however, was his rediscovery of Cyprian Norwid.

The lyrical poet Kazimierz Tetmajer (1865–1940) early achieved popularity with his nostalgic and pessimistic *Poezye* (eight series, 1891–1924). The self-conscious, generalized melancholy of much of his verse, however, is less impressive, seen in the perspective of time, than his prose, which is characterized by a greater vigour and precision of observation. The five volumes of *Na skalnym Podhalu* (1903–10; Eng. trans. *Tales of the Tatras*, 1941) were conceived with epic intent and contain some effectively stylized folk material; they are probably his most enduring work. A more interesting poet, Jan Kasprowicz (1860–1926), was of peasant origin; he presented themes from his personal experience directly and without the sentimentality of such earlier writers as Lenartowicz. His principal contribution to Polish literature, however, lies in the structure of his longer lyrical poems; the peni-

tential poems contained in the volume *Ginącemu światu* ("To the Dying World," 1902), especially the impressive "Moja pieśń wieczorna" ("My Evening Song"), employ a technique of association, quotation, musical repetition, and free metre which anticipates the early style of such poets as T. S. Eliot. He also made many translations of English literature, from Chaucer to the 20th century. Tadeusz Miciński (1873–1918), who is regarded as a forerunner of Expressionism and Surrealism, wrote philosophical and mystical poems and plays in which flashes of brilliantly imaginative imagery alternate with disordered extravagance. His most notable publications were the collection of poems *W mroku gwiazd* ("In the Darkness of the Stars," 1902), and the play *Książ Potemkin* ("Prince Potemkin," 1906). The lyric poet Leopold Staff (1878–1957), whose work shows great variety and technical dexterity, was at this period associated with the "Young Poland" movement. His first volume, *Sny o potęgę* ("Dreaming of Power"), was published in 1901. Some of his finest work, however, was written after World War II.

A leading exponent of the movement's new aesthetic theories was Stanisław Przybyszewski (1868–1927), who in 1898 became editor of the Cracow literary magazine *Życie* ("Life"). His mannered novels and plays, luridly exploiting psychological themes, enjoyed a meteoric success which did not, however, outlast his lifetime. Stephen (Stefan) Żeromski (1864–1925), possibly the most widely read early 20th-century novelist in Poland, reveals his passionate concern for social justice in novels, plays, and short stories in which the characters are shown in conflict with circumstances, paying for their adherence to principle by loss of personal happiness. An excess of realist documentation, however, expressed in an overblown lyricism of style, frequently vitiates the power of his later work. Władysław Stanisław Reymont (q.v.; 1868–1925), himself of peasant stock, adapted the naturalistic technique to create a vision of peasant life, epic in scale, in his novel cycle *Chłopi* (four volumes, 1904–09; Eng. trans. *The Peasants*, 1924–25), for which he received the Nobel Prize in 1924. Another writer who used his own experience of peasant life in his novels was Franciszek Smreczyński (pseudonym Władysław Orkan; 1876–1930), who in *Komornicy* ("The Tenant Farmers," 1900) and *Drzewieje* ("In Olden Days," 1912), for example, described with mature realism the life of the inhabitants of the country at the foot of the Carpathians. The novels and stories of Wacław Sieroszewski (1858–1945) have picturesque settings in Siberia, Japan, and other exotic lands. One of the most effective novels of the period, *Żywoć i myśli Zygmunta Podfilipskiego* ("Life and Thought of Zygmunt Podfilipski," 1898), by Józef Weyssenhoff (1860–1932), presents an ironic portrait of the egoist in society. Wacław Berent (1873–1940) parodied the positivist ideal in his first novel *Fachowiec* ("The Professional Man," 1895). In *Próchno* ("Rotten Wood," 1901) he portrayed with biting irony the late 19th-century decadence of life and art through a vivid evocation of various typical "Bohemian" groups—artists, poets, musicians, journalists—at the turn of the century; and in *Ozimina* ("Autumn Sowing," 1911), in many respects a Symbolist novel, he foreshadowed the associative structure and technique of James Joyce's *Ulysses* (1922). His *Zywe kamienie* ("The Living Stones," 1918), a scrupulously stylized recreation of the life of the 14th-century wandering scholars, stresses the unity of medieval culture and Poland's place within it. An audacious experiment in form and structure, antedating the development of the psychoanalytical novel in western Europe by several years, was *Paluba* . . . (1903; new ed. 1948) by Karol Irzykowski (1873–1944). In its motivation and behaviour are presented at several "subjective" levels and from different viewpoints, ingeniously cemented by the author's own analyses and cross-references as in a scientific study. Irzykowski was also a penetrating critic of modern Polish literary theory, and the first to give serious attention to the cinema as an art form in *Dziesiąta muza* ("The Tenth Muse," 1924).

Stanisław Brzozowski (1876–1911) was an outstanding literary critic who developed an original philosophy of the relationship between art and life, stressing the moral function of creative activity and the need for the critic to represent the "moral consciousness" of his age. In *Legenda Młodej Polski* ("The Legend of

Young Poland," 1909), he analysed the weakness of the literature of the period and expounded his own view of the unity of all work—physical, technical, intellectual, and artistic. He opposed both positivist utilitarianism and the aestheticism and divorce from reality of the "Young Poland" movement; and his penetrating critical analyses of Polish culture remain of value.

PORTRAIT IN PASTELS, 1894. IN THE
MUZEUM NARODOWE, WARSAW

Stanisław Wyspiański (1869–1907) possessed manifold talents: painter, draftsman, designer of stained glass, and typographer; he was also a dramatist of genius. His plays show the influence of Maurice Maeterlinck and Wagner, and of his own interests as a graphic artist, with their emphasis on static mood and tendency to seek a synthesis of pictorial, musical, and dramatic elements. In them, Wyspiański reformed elements from classical tragedy and mythology, the Polish Romantic drama, and national history, in a complex whole. His *Wesele* ("The Wedding," 1901) is a visionary parable of Poland's past, present, and problematical future presented in the symbolic but concrete terms of an actual marriage in his native region of Cracow. Cast in the form of the traditional puppet-theatre (*szopka*) play, it is a masterpiece of evocative allusion, tragedy, and humour.

The literature of the period as a whole is characterized by close contact with western European literatures, but in their search for a new poetic language writers such as Wyspiański turned back for guidance to the Polish Romantics, especially to Słowacki and the newly rediscovered Norwid.

RESTORED INDEPENDENCE

The restoration in 1918 of Polish independence decisively affected the character of Polish literature. Taken as a whole, the period from 1918 to 1939 was characterized by richness and variety, and by increasing contact with other European literatures. The publication of many translations, from French, German, and English especially, was a sign of the revival of interest in western literary developments.

Poetry.—For nearly the whole of the first decade after 1918, lyric poetry predominated. A periodical called *Zdrój* ("The Fountainhead"), published in Poznań from 1917 to 1920, displayed certain affiliations with German Expressionism. During the first stage of his career Józef Wittlin (1896–) was a member of this group. His stirring *Hymny* (1920) depict the horrors of war, and in the novel *Sól ziemi* (1936; Eng. trans. *Salt of the Earth*, 1939) he portrays wartime experiences through the eyes of a humble man.

The "Skamander" Group.—In Warsaw several young poets of different tendencies formed a group called *Skamander*, from the name of their monthly publication. This group had no general program, but was held together by the enthusiasm of its members arising out of the new situation, and their desire to forge a new, poetic language, closely attuned to the experience of modern life. It was headed by Julian Tuwim (1894–1954), a lyrical poet of unusual emotional power and extreme linguistic sensitivity, whose very facility in time blunted the edge of his originality. Two of his many collections of verse are the early *Czyhanie na Boga* ("Lurking God," 1918) and *Biblia cygańska* ("The Gypsy Bible," 1933). During World War II, while in Brazil and the United States, he wrote a discursive, autobiographical poem of great length in the nine-syllable line, *Kwiaty polskie* ("The Polish Flowers," 1949). Kazimierz Wierzyński (1894–), in his *Laur olimpijski* ("Olympic Laurels," 1927), sang the praises of sport, health, and physical beauty. The poetry of Jan Lechoń (pseudonym of Leszek Serafinowicz; 1899–1956) treated intellectual and national subjects in a balanced classical form. Antoni

Stonimski (1895–), another poet of the group, revealed in his writing his discursive, rhetorical temperament.

Among sympathizers with *Skamander* was a woman poet of great talent, Maria Pawlikowska-Jasnorzewska (1895–1945), who had an exceptional gift for concentration, precision, and control in the formulation and expression of emotion. Also connected with the *Skamander* group at this period was Władysław Broniewski (1898–1962). A poet of great power and feeling, with strong left-wing sympathies, he became the master of the revolutionary lyric, and in his unusually popular poetry used traditional metres and forms to express practical concern with current social and ideological problems.

A writer of great importance was Bolesław Leśmian (1878–1937). His symbolic, expressionist poetry, containing elements of fantasy and fable, is remarkable for the inventiveness of its vocabulary, its sensuous imagery, and its philosophic content, which in some ways anticipates the ideas of the Existentialists. Although his output was small—he published only three notable collections: *Łąka* ("The Meadow," 1920), *Napój cienisty* ("The Shadowy Drink," 1936), and *Dziejba leśna* ("Woodland Tale," 1938)—he became increasingly recognized as the most outstanding Polish lyric poet of the 20th century.

The "Awangarda."—Among other experimental movements active at this time, the *Awangarda* followed the revolutionary trends in poetry, Futurism in particular, in France, Italy, and Spain. This group, led by Tadeusz Peiper (1891–), produced few finished works of art, but had a widespread influence upon the regeneration of poetic technique. One of its adherents, Julian Przyboś (1901–), ranked among the outstanding poets of the period after World War II. Józef Czechowicz (1903–39) assimilated traditional and regional elements to the new style to produce the concentrated lyricism of such collections as *Dzień jak codzień* (1930).

Prose.—Prose writing reached ascendancy in the second decade of independence. The early novels and short stories of Zofia Nałkowska (1885–1957) belonged to the "Young Poland" movement, and aimed to reveal the feminine psyche (e.g., *Kobiety* ["Women"], 1906). Later, she turned to other themes, striving for narrative objectivity and technical simplicity, and in such novels as *Romans Teresy Hennert* ("The Romance of Teresa Hennert," 1923), *Granica* ("The Frontier," 1935), and *Węzły życia* ("The Threads of Life," 1948–54) she developed her talent for psychological analysis, but applied it to the revelation of reality. Ferdynand Goetel (1890–1961) wrote of his experiences in Russia during the Revolution in *Kar-Chat* (1923) and *Z dnia na dzień* ("From Day to Day," 1926), a novel interesting for its use of the diary form within the main narrative as a means of exploring character. Two women novelists of distinction were Zofia Kossak-Szczucka (1892–) and Maria Kuncewiczowa (1899–). Juliusz Kaden-Bandrowski (1885–1944) evolved a style of his own, marked by an experimental realism. His *General Barcz* (1923), *Czarne skrzydła* ("Black Wings," 1928–29), and *Mateusz Bigda* (1933) are outstanding examples of a prose style both naturalistic and expressionistic, and treat social and political themes with violent power. Michał Choromański (1904–) achieved great success with the novel *Zazdrość i medycyna* ("Jealousy and Medicine," 1932), which used experimental methods of narrative sequence and was remarkable for its clinical analysis of character. A writer skilled in reflecting subtleties of perception was Bruno Schulz (1892–1942), author of *Sklepy cynamonowe* ("Cinnamon Shops," 1934), which presents the oddity and mystery of existence in a style combining Expressionism and Surrealism. His prose is reminiscent of Kafka, whose works he translated into Polish. Jarosław Iwaszkiewicz (1894–), co-founder of the *Skamander*, wrote many novels and short stories in a vivid, succinct prose style, and was also the author of critical studies of Chopin and the 20th-century composer Karol Szymanowski.

Tadeusz Boy-Zeleński (1874–1941), who had begun his literary career in the 1890s by writing songs and light poems, became one of the most important literary critics of the period. His attitude was influenced by his knowledge of French literature—he translated more than 100 volumes from French, ranging from the *Chanson de Roland* to Proust, in the Polish style most appropriate

to each work, and in his introductions and commentaries provided a survey of French literature. In his treatment of Polish writers, he showed an interest in biographical and psychological rather than purely literary considerations and provided revaluations of most of the great figures of the past. His theatrical reviews and his journalism reveal his critical acumen and originality and his hatred of hypocrisy and cant.

The essay form was represented by Jan Parandowski (1895–), whose main theme in his essays was the classical culture of Greece and Rome. Parandowski was also a novelist, his best-known work being a biographical novel about Oscar Wilde, *Król życia* ("King of Life," 1930). A subversive attack on intellectual and social conventions was launched in *Ferdydurke* (1937), a novel by Witold Gombrowicz (1904–) which displayed a satirical talent reminiscent of such western writers as Alfred Jarry (q.v.). The continuing taste for the cyclic novel was catered to by several novelists: for example, Maria Dąbrowska (1892–1965), with *Noce i dnie* ("Nights and Days," four volumes, 1932–34), the outstanding modern Polish example of a chronicle novel in epic style, treating the life of "average people" between the 1860s and 1914 with high artistic ability.

Drama.—The drama was the weakest of the literary kinds during this period. Włodzimierz Perzyński (1878–1930), a novelist who wrote realistic comedies, and Karol Hubert Rostworowski (1877–1938), author of poetic dramas, both belonged to the previous period. Toward the end of his career Rostworowski began writing plays in prose on social and moral problems, which at times attained the monumental grandeur of classical tragedy. Jerzy Szaniawski (1887–) tried to revive Symbolist drama. The novelist Zofia Nałkowska wrote two successful plays which have remained in the repertory: *Dom kobiet* ("A Household of Women," 1930) and *Dzień jego powrotu* ("The Day of His Return," 1931). The experimental dramas of Stanisław Ignacy Witkiewicz (1885–1939) are of interest chiefly for their expression of his antirealist aesthetic theories. Witkiewicz, who was also a painter, novelist, and critic, developed many of the ideas of the *Awangarda*, and applied the principles of "pure form" to painting and drama. His plays foreshadowed the work of such later dramatists as Eugène Ionesco.

LITERATURE AFTER WORLD WAR II

The impact of the war, the tragic experiences of occupation, and the establishment in 1945 of a people's republic decisively affected the character of literature in Poland, and also led to the development of an *émigré* literature, written by Poles in exile who, though scattered in many countries, struggled to preserve their national identity.

Writers in Exile.—Among *émigré* writers were many who had become famous in the years between the wars—lyrical poets of the *Skamander* group (Wierzyński, Lechoń, Stanisław Baliński, [1898–]), and former associates of the *Awangarda* movement, among them Józef Łobodowski (1909–), Marian Czuchnowski (1909–), and Czesław Miłosz (1911–). The last two were also notable as prose writers (Miłosz won the *Prix Littéraire Européen* for his *Zdobycie władzy*—"The Usurpers"—first published as *La Prise du pouvoir*, 1953; Polish version, 1955).

Many *émigrés* wrote memoirs of their experiences in German or Soviet prisons and forced-labour camps. The most accomplished as literature was *Inny świat* (*A World Apart*, 1951; Polish version, 1953) by Gustav Herling-Grudziński (1919–). *Sprawa Józefa Mosta* (1953), by Herminia Naglerowa (1890–1957), a distinguished novelist of the period between the wars, is an artistic

projection of her experiences in a Soviet prison. Jerzy Pietrkiewicz (1916–), the poet, novelist, and literary historian whose early work was published in Poland during World War II, later wrote mainly in English (e.g., the novels *The Knotted Cord*, 1953, and *Isolation*, 1959). Other Polish writers in exile included the essayists Jerzy Stempowski (pseudonym Paweł Hostowiec; 1894–) and Stefania Zahorska (1896–1961); and the literary historians Tymon Terlecki (1905–), Wiktor Weintraub (1908–), and Maria Danilewiczowa (1907–), who also wrote novels.

Writers in Poland.—In Poland, the years immediately after World War II were notable for the publication of works written during the occupation or by writers who had been confined in concentration camps and prisons. The dominant theme during the years 1945–48 was the attempt to come to terms with Fascism and with the tragic experiences of war. This is exemplified particularly in the short stories of Tadeusz Borowski (1923–51), a prisoner at Auschwitz who in the collections *Pożegnanie z Marią* ("Farewell to Mary") and *Kamienny świat* ("World of Stone"), both published in 1948, explored the depths of human depravity and degradation as revealed in his own experiences of life in a concentration camp; and in those of Adolf Rudnicki (1912–), who treated moral and philosophical themes in lyrical prose, and described, in such collections as *Szelepsir* ("Shakespeare," 1948) and *Ucieczka z Jasnej Polany* ("Flight from Jasna Polana," 1949), the wartime fate of the Jewish community in Poland. Another theme, shown, for example, by the novel *Popiół i diament* (1948; "Ashes and Diamonds," 1962) by Jerzy Andrzejewski (1909–), was the examination of the moral and philosophical controversies which accompanied the political and social changes of the postwar period.

During the years 1949–54 the literature of "social realism" gained ground. Writers were chiefly concerned with depicting the revolutionary social changes taking place in Poland. In form, they strove to emulate the great realist writers of the 19th century. A new type of hero was created (the so-called "positive" hero)—the ordinary man or woman actively engaged in "productive" work—and in general those elements in the social scene which served to present the idea of revolutionary progress were accentuated. The main writers of the "social realist" movement were Leon Kruczkowski (1900–62), a prewar exponent of the Marxist novel (e.g., the historical novel *Kordian i Cham* ["Kordian and the Boor"], 1932), whose outstanding plays *Niemcy* ("The Germans," 1949) and *Pierwszy dzień wolności* ("The First Day of Freedom," 1960) were successfully performed in several other European countries; Igor Nowak (1903–); Julian Strykowski (1905–); and Kazimierz Brandys (1916–), whose development typifies postwar tendencies in Polish literature. He had earlier published the epic novel cycle *Miedzy wojnami* ("Between the Wars," 1947–51), and his "social realist" novel, *Obywatele* ("Citizens"), appeared in 1954.

Among writers of the "social realist" period who stood aside

from political involvement were the poet Konstanty Ildefons Gałczyński (1905–53), who combined lyricism with a grotesque fantasy in a highly original manner; and the philosophical, reflective poet and essayist Mieczysław Jastrun (1903–), who in his later work (e.g., the verse collection *Intonacje* ["Intonations"] and the series of essays *Mit Śródziemnomorski* ["Mediterranean Myth"], both published in 1962) was seen to be moving toward Existentialism. A group of Catholic writers actively opposed to "social realism" included Antoni Głubiew (1907–), author of the epic novel cycle *Bolesław Chrobry* (1947–55); the prose writer and dramatist Jerzy Za-

wieyski (1902–); and the historical novelist, Hanna Malewska (1911–).

The weakness of the "social realist" movement—its attempt to impose a political pattern on creative writing, its avoidance of themes arising from contemporary social, political, and moral conflicts—arose in part from the political and cultural stranglehold of the Stalinist regime. In the period beginning in 1954–55, writers began to criticize these weaknesses severely and to oppose them in their work. Andrzejewski, for example, presented contemporary ideas and problems in two novels combining historical and metaphorical treatment—*Ciemności kryją ziemię* (1957; Eng. trans. *The Inquisitors*) and *Bramy raju* ("The Gates of Paradise," 1960). Teodor Parnicki (1918–), author of historical novels set in the period of early Christianity, employed a background of conflict between several cultures as a pretext for a penetrating analysis of contemporary philosophical and political problems. His works include *Koniec zgody narodów* ("End of the 'Agreement Between the Nations,'" 1955); *Nowa baśń* ("A New Fairy-Tale," 1962); and *Tylko Beatrycze* ("Only Beatrice," 1963). Brandys criticized Stalinist political theory and practice in his novel *Matka królów* ("Mother of Kings," 1957). The short stories of the young Marek Hłasko (*Cmentarze: Następny do raju* ("The Graveyard: Next Stop Paradise," 1958) showed a new, and pessimistic, type of realism.

At the same time, the political "thaw" resulting from the events of 1956 made it more possible for writers to renew their contacts with the West. As a result, Polish literature was enriched and stimulated, and a new period of development and experiment was initiated. In prose, although traditional realistic treatment of social and psychological themes continued—for example, in the work of Wilhelm Mach (1917–), whose well-known novel *Góry nad czarnym morzem* ("Mountains by the Black Sea," 1961) was an attempt to translate into Polish terms the French "anti-novel"—the development of the literary essay as a vehicle for philosophical and intellectual discussion and comment, and the rise of satire, showed the tendency to experiment. Among essayists were Brandys (e.g., his series *Listy do Pani Z*, 1958–60) and Tadeusz Breza (1905–), who analyzed contemporary life and ideas in a prose of Proustian subtlety (e.g., in *Spizowa brama* ["The Bronze Gate"], 1959, an objective description of present-day life in the Vatican, several times reprinted and widely translated). One of the most interesting writers of the new generation was Sławomir Mrożek (1930–), whose short stories combine satiric and grotesque elements, and whose *avant-garde* plays *Indyk* ("The Turkey") and *Policjanci* ("The Policemen") have been successfully performed in western Europe and the United States.

The poetry of the period was also notable for its expression of intellectual and philosophical ideas. The work of Stanisław Jerzy Lec (1909–), a satirist and poet famous for his skeptical philosophical aphorisms (e.g., *Mysli nieuczesane* ["Unkempt Thoughts"]), has been translated in both western Europe and the United States. Zbigniew Herbert (1924–) is an outstanding representative of the new intellectual poetry: his most notable collection is *Studium przedmiotu* ("Study of a Subject," 1961). Perhaps the most interesting of the poets of the postwar period, however, is Tadeusz Różewicz (1921–), whose first collection of verse, *Niepokój* ("Trouble"), appeared in 1947. His influence on the younger lyrical poets has been profound. His work is marked by a preoccupation with moral and intellectual themes, and frequently refers to the tragic experiences of World War II; and in style he shows an original development of the basic forms of the *Awangarda* poets. Różewicz has also written plays, in the style of Eugène Ionesco; one is published, with poems, in *Kartoleka* ("The Card File," 1961).

Of writers belonging mainly to the prewar period, several continued to publish, among them the poet Leopold Staff (see above); the novelist Maria Dąbrowska, whose reputation was enhanced by her collection of short stories *Gwiazda zaranna* ("Morning Star," 1956) and by a series of critical essays on Conrad (*Szkice o Conradzie*, 1959); and the novelist and critic Jarosław Iwaszkiewicz, whose outstanding epic novel *Slawa i chwala* ("Fame and Praise") appeared between 1956 and 1962. Other critics and es-

sayists included Artur Sandauer (1913–); Jan Kott (1914–), whose *Szkice o Szekspirze* (1961; trans. as *Shakespeare Our Contemporary*, 1964) has been widely translated; Kazimierz Wyka (1910–); and Stefan Żółkiewski (1911–).

POLISH ORTHODOX CHURCH was originally part of the Russian Orthodox Church but became independent after World War I when large numbers of Orthodox faithful found themselves part of the new Polish state. Most of the Orthodox people lived on the eastern borders of Poland and were incorporated into the U.S.S.R. at the end of World War II; this reduced the numbers of the church from about 4,500,000 (1939 est.) to about 350,000 (1948 est.).

On June 14, 1922, the Episcopal Synod of the Polish Church proclaimed its independence, a decision which evoked protests from the Russian Orthodox Church. On Nov. 13, 1924, the church was officially recognized as autocephalous by the ecumenical patriarch of Constantinople. The canonicity of this act was disputed by the Russian Church on the ground that Orthodox custom requires the consent of the mother church before a church can become autocephalous.

At the end of World War II Metropolitan Dionysius of Warsaw was head of the Polish Church, and he declined to submit to the Russian Church. He was therefore prevented on May 4, 1948, from fulfilling his functions by the Polish authorities, and an ecclesiastical delegation went to Moscow asking for autocephalous status on the ground that the 1924 decision was invalid. This was granted by the Russian Church on June 22, 1948. In 1951 at the request of the Polish Church a Russian bishop was nominated to be its head because no suitable Polish churchman could be found. The patriarch of Constantinople did not recognize these actions and continued to regard Dionysius as head of the church, although he was unable to function. This dispute was one example among others of unresolved differences as to the limits of the authority of the various patriarchs. See also **ORTHODOX EASTERN CHURCH**.

(H. M. W.)

POLISH SUCCESSION, WAR OF THE, the European war that broke out in 1733, so named because the rivalry between two candidates for the kingdom of Poland was taken as the pretext for hostilities by governments whose real quarrels with each other had in fact very little connection with Polish affairs.

Poland was an elective monarchy; and Augustus II (q.v.) of Poland, who was also elector of Saxony as Frederick Augustus I, died on Feb. 1, 1733. Thereupon Austria and Russia decided that their interests would best be served if Augustus II's son, Frederick Augustus II of Saxony, were to become king of Poland as Augustus III (q.v.). Most Poles, however, favoured a candidate of their own nationality, Stanisław Leszczyński (see **STANISLAW I**). The latter had not only been king of Poland under Swedish protection from 1704 to 1709 (while Augustus II was temporarily deposed), but also had subsequently become the father-in-law of Louis XV of France.

Louis XV, despite the cautious objections of his chief minister, the cardinal de Fleury, had more grounds than those of kinship with Leszczyński for opposing Austria. The Austrian archduchess Maria Theresa, whom the Holy Roman emperor Charles VI had made heiress to the Habsburg lands by his Pragmatic Sanction (*q.v.*), was about to marry Francis Stephen, duke of Lorraine (*see* FRANCIS I, Holy Roman emperor); and this marriage threatened to establish Habsburg interests in Lorraine to France's disadvantage.

Spain was ready to make war against Austria for the aggrandizement of the infante Don Carlos (*see* CHARLES III, king of Spain) in Italy. Don Carlos had already got the duchies of Parma and Piacenza and was expecting to succeed to Tuscany, as Gian Gastone, the last Medici grand duke, was childless; but his mother, Isabella (*q.v.*) Farnese, coveted Austria's kingdom of Naples-Sicily for him also, as well as Austrian Lombardy (Milan and Mantua). Sardinia-Savoy also had designs on Austrian Lombardy.

Antonio Felice de Monti, France's ambassador to Poland, propped Leszczyński with promises and money and reconciled the houses of Potocki and Czartoryski (*qq.v.*) in his interests. Leszczyński was elected king by a *sejm* (parliament) of 12,000 in Warsaw on Sept. 12, 1733, but had to take refuge in Gdansk as a Russian army 30,000 strong was already approaching Warsaw. Then a puppet *sejm* of 3,000, dominated by the families of Radziwill and Sapieha (*qq.v.*), elected Augustus III on Oct. 5.

France signed the Treaty of Turin with Sardinia-Savoy on Sept. 26, 1733, declared war against Austria on Oct. 10, and made the first "Family Compact" of the two Bourbon kingdoms by alliance with Spain on Nov. 7. The French overran Lorraine to attack the Austrian Rhineland and sent their marshal Villars with an army over the Alps to invade Lombardy in cooperation with the Savoyards; and a small force was dispatched by sea to relieve Gdansk. The French marshal Berwick (*q.v.*), however, was killed besieging Philippsburg; Prince Eugene (*q.v.*) of Savoy, on the Austrian side, defended southern Germany effectively; the invaders in Lombardy were unable to take Mantua; and on June 28 Gdansk fell to the Russians. Escaping to Prussian Königsberg (Kaliningrad), Leszczyński in August appealed to the Poles to continue the struggle, and in November a confederation to support him was formed at Dzikow, near Sandomierz, with Adam Tarlo as its leader.

Meanwhile, Don Carlos and a Spanish army of 40,000 under the conde de Montemar (José Carrillo de Albornoz) had marched across Tuscany and the Papal States to Naples. His victory over the Austrians at Bitonto (May 25, 1734) enabled Don Carlos to proceed to Sicily to be crowned king at Palermo. The Austrian field marshal C. F. von Mercy attacked Parma in the absence of Don Carlos but was defeated and killed in battle there (June 29).

Dissension between Spaniards and Savoyards made the Italian campaign of 1735 inconclusive, and Fleury feared that the British and the Dutch might intervene to help Austria. Accordingly the preliminary Peace of Vienna, between France and Austria, was signed on Oct. 3, 1735. This stipulated that Don Carlos should keep Naples-Sicily but should renounce Parma and Piacenza to Austria and his claims on Tuscany to Francis Stephen of Lorraine; Francis Stephen should renounce Lorraine to Stanislaw Leszczyński, on whose death it should pass to France; Augustus III should be recognized as king of Poland; and Sardinia-Savoy should have Novara and Tortona from Lombardy. The final Franco-Austrian Peace of Vienna (Nov. 18, 1738) confirmed this general post, France also conditionally guaranteeing the Pragmatic Sanction. Since Leszczyński had renounced his crown (Jan. 26, 1736), the Dzikow confederacy had recognized Augustus, and Augustus in 1737 granted Courland as a fief to the Russian empress Anna's favourite, E. J. Biron (*q.v.*). The outstanding belligerents acceded to the peace in 1739.

POLITIAN (ANGELO AMBROGINI) (1454–1494), Italian poet and humanist, the friend and protégé of Lorenzo de' Medici, and one of the foremost classical scholars of the Renaissance, was born at Montepulciano, Tuscany, on July 14, 1454. He was the eldest of five children of Benedetto Ambrogini, a doctor of law, and of Antonia Salimbeni. From the Latin name of his birthplace, *Mons Politianus*, he derived the name (Politianus; Italian form,

Poliziano; anglicized as Politian) by which he is generally known. The murder of his father in May 1464 left the family poverty-stricken, and not later than 1469 Politian was sent to Florence to live with a cousin. To find a patron he started to write Latin epigrams in praise of various Florentine citizens, and attracted the attention of Lorenzo de' Medici (*see* MEDICI family), to whom he dedicated the first two books of his Latin translation of the *Iliad*. In c. 1473 he entered the Medici household, but without specific duties, and was thus able to study in the Medici library until, in 1475, he was entrusted with the education of Lorenzo's eldest son, Piero, then aged three. In 1477 he was given as a benefice the priory of San Paolo. In Florence he attended the lectures in philosophy given by Marsilio Ficino (*q.v.*) and the university courses of Cristoforo Landino and of the Greek masters John Argyropoulos (*q.v.*), Demetrius Chalcondyles (*see* under CHALCONDYLES, LAONICUS), and Andronicus Callistus. Although influenced by Ficino's Neoplatonic ideas, he was more attracted by poetry and philology. His translation of the *Iliad*, books ii–v, into Latin hexameters (1470–75) brought him his first renown. Between 1473 and 1478 he produced Latin verses which are among the best examples of humanist poetry: they include elegies, odes, and epigrams (of particular merit are the elegies *In violas* and *In Lalagen* and the ode *In puellam suam*); to the same period belong the poetic invectives *In Mabilium* and the *Sylva in scabiem* (written 1475, but unpublished until 1954), in which he describes realistically the symptoms of scabies.

His poetic masterpiece of this period is, however, a vernacular poem in ottava rima, *Stanze per la giostra del Magnifico Giuliano de' Medici*, composed between 1475 and 1478, which is one of the great works of Italian literature. The poem describes the love of "Julio" (*i.e.*, Giuliano de' Medici), for "Simonetta" (*i.e.*, Simonetta Cattaneo; d. 1476, wife of Marco Vespucci) by means of a poetic transfiguration in which beauty is glorified according to humanist ideas. Stylistically it is influenced by Latin epic and encomiastic poems, and reveals the author's taste for refined poetry. It was interrupted at book ii, stanza 46, probably because of Giuliano's death in 1478.

Politian was, with Lorenzo de' Medici, one of those mainly responsible for the revaluation of vernacular literature. It is generally believed that it was he who wrote the dedicatory letter, tracing the history of vernacular poetry and warmly defending

it, which accompanied the so-called *Raccolta Aragonesa*, a collection of Tuscan verse sent by Lorenzo de' Medici to Federico d' Aragona, the second son of the king of Naples, in c. 1477. Although there is no definite evidence of Politian's authorship, there can be little doubt that he must have acted as Lorenzo's adviser in the constitution of this collection, which had great importance in the diffusion of Tuscan literature in southern Italy in the late 15th century.

Politian was with Lorenzo and Giuliano when the latter was killed by the Pazzi on April 26, 1478; on this episode he wrote a dramatic report in a Sallustian style, *Pactianae coniurationis commentarium* (1478). In May 1479, as a result of a quarrel with Lorenzo's wife, Clarice Orsini, he was expelled from the Medici household. In December, instead of accompanying Lorenzo on a difficult diplomatic mission to Naples, he undertook a series of journeys in northern Italy. In Venice he met the famous humanist Ermolao Barbaro, and the two became friends. In Verona he expounded Catullus with much success. Then, attracted to Mantua by the splendour of the Gonzaga court, he found a new patron in

MANSELL—ALINARI
PORTRAIT OF POLITIAN, DETAIL
FROM "ZACCHARIAS AND THE AN-
GEL" BY GHIRLANDAJO: 1490–94

Cardinal Francesco Gonzaga. It was for a court occasion that he wrote in Mantua the *Favola d'Orfeo* (1480), a short dramatic composition in the vernacular based on the myth of Orpheus and Eurydice, and inspired by the same humanist ideal of beauty which pervades his *Stanze*. The *Favola* is less refined than the *Stanze*, but it nevertheless reveals the author's poetic genius. During his stay in Mantua Politian repeatedly wrote to Lorenzo asking to be recalled to Florence, and in August 1480 he was at last invited to return and was again entrusted with Piero's education. Thanks to Lorenzo he was appointed to the Florentine chair of Latin and Greek (November 1480), but was not readmitted to the Medici household and went to live at his priory of San Paolo.

At the Florentine university he gave four inaugural lectures in verse (*Sylvae*): *Manto* (1482), on Virgil's poetry; *Rusticus* (1483), on the bucolic poems of Hesiod and Virgil; *Ambra* (1485), on Homer; and *Nutricia* (1486), on the different genres of Greek and Latin literature. In opposition to the predominant Ciceronianism of his contemporaries, he maintained that modern writers should elaborate the classical tradition in their own way.

In 1488 he took part in a diplomatic mission to Pope Innocent VIII; and in 1491 he traveled to Bologna, Padua, and Venice to trace manuscripts for the Medici library. Otherwise he spent the last years of his life in Florence. His writings of this last period include a Latin translation of Epictetus' *Manual* (1479); a collection of *Detti piacevoli* (witty sentences), composed in the vernacular between 1477 and 1479; Greek epigrams; a number of vernacular *Canzoni a ballo* and *Rispetti* which show his taste for popular poetry; and Latin letters on problems of style and literature.

His most important work on classical philology is the *Miscellanea* (1489), a collection of 100 notes (*centuria*) on classical texts: this work marked a turning point in the history of classical philology. The autograph of an uncompleted second *centuria* of the *Miscellanea* was discovered in 1961 and is in the Fondazione Cini Library, Venice. Politian died at Florence on the night of Sept. 28–29, 1494.

POLITICAL PHILOSOPHY. The traditional problems of political philosophy have been the nature and the justification of political obligation and authority. There are here two essentially different sets of questions. First, there are the questions how men came together under governments and what were the motives which originally influenced them to do this and which still prevail to keep them obedient to government orders. These are questions of fact and they are properly studied by social historians, sociologists and psychologists; but before sociology and psychology were established as independent sciences, many political philosophers included speculations on these historical and psychological topics in their works. The second question is that of the ethical justification of obedience to government; or, if we look at it from the point of view of the rulers, that of the moral basis of their authority. This question is the proper concern of political

philosophy. In this article some representative answers to it are considered.

Force.—One answer is that there is no ethical justification for government. Rulers govern because they have the power and consequently they govern in their own interest. Subjects obey because they cannot help it; they are the tools of the rulers. Greek sophists, of whom Thrasymachus in Plato's *Republic* is an example, first gave this answer, but it is still alive, for it was the view of the 19th-century anarchists and is still the official Marxist doctrine. "The State is nothing more than a committee for the administration of the affairs of the ruling class" (*Communist Manifesto*); and "With the disappearance of classes the State too will disappear" (Friedrich Engels). How far this is a complete answer will depend on the merits of the alternative answers which follow.

The Organic Theory.—The state has been likened to an organism, the citizens to its organs: "We are members one of another." As an eye is good when it best serves the organism as a whole, so the good citizen is he whose whole life is dominated by the ideal of state service. If he fails to perform his civil functions he should be liquidated ("If thine eye offend thee, cut it out . . ."). The government is the brain of the state, the organ whose function is the control of the other organs in the interest of the whole body.

The difficulties in this theory are these. First, it tends to assume that actual states are ideal, that their governments do control the citizens in the interest of the whole. Secondly, it assumes that there is something correctly described as "the interest of the whole state," to which individual interests can be sacrificed. But there is no such thing: the interests of some can be sacrificed to the interests of others, but the good of the state must be analyzed without remainder into the goods of individual men (as must public health or social welfare). Thirdly, this theory assumes that the state is the only form of association, as was the Greek city-state in the time of Plato and Aristotle when the theory first appeared. But the scriptural quotations cited above stressed the unity and organic character not of the state but of the church. Nowadays, with the vast multiplication of associations, it is impossible for one type of association, the political, to claim the complete self-sufficiency, the overriding authority and the undivided loyalty which the organic theory of the state requires.

The General Will.—On this view it was argued that a moral rule, to be moral, must be self-imposed, and the problem of political authority thus became that of self-government. At first sight this leads straight to democracy as the only legitimate form of government. We have an obligation to obey laws only if we ourselves have made them. But in Jean Jacques Rousseau, who originated this theory, the argument took a different direction, in which it was further developed by Hegel and his followers (e.g., Bernard Bosanquet, *The Philosophical Theory of the State*). My real good must be distinguished from what at the moment I actually want. My permanent aim, if I am reasonable, is my real good, though my passing desires may thwart and impede it. This distinction between ends or aims is then carried over as a distinction between two selves within me, my rational, true, permanent, higher self and my lower, fluctuating, impulsive, desiring self. When a law compels me to abstain from murder or blackmail it expresses my higher against my lower self. Thus when I obey the law, I am obeying my own real will, the law is self-imposed, and I am "forced to be free" (Rousseau). Since "the good" is the same for all rational men, the real selves of all will be identical and the state can be said to have (or be) a single will; the general will. There is thus attributed to the state a unity of a type higher even than that of an organism, the unity of a self. In Hegel and his successors this led to a kind of deification of the state as "the march of God upon earth" (Hegel) and as the sole source of moral right and the sole centre of human devotion.

Parallel objections to those against the organic theory are valid here. What is called "the will of the state" is in fact the will of the government, and governments are just as capable as individuals of making irrational decisions based on desire or short-term interest. A state decision is in any sense my responsibility only if I have had some actual share in bringing it about. Much of morality and much of human value is no concern of the state at

all. Finally it may be objected that, even if all this theory were literally defensible, what is said of the state could be said of any other association: trade unions, colleges, churches and athletic clubs would have (or be) general wills too.

Pluralism.—From this last criticism there emerged a theory called pluralism in contrast with the "monistic" theory of Rousseau and the Hegelians with their single supreme association. The pluralists varied in their attitude to the state. Some of them found no rational function for the state to perform (except making wars). There they joined hands with the Marxists, who were pluralists so far as they substituted for the state a complex of voluntary associations. Others held that there were certain functions which the state should perform, but these gave it no supremacy over other associations, no monopoly of loyalty, no right to stand as the sole source of morality and no claim to obedience beyond the affairs which were its special charge.

The Liberal View.—These theories have now few defenders; the living issues in politics are to be sought elsewhere. They are here considered under labels which are not used with any suggestion that they correspond to the lines between political parties. The views here considered are distinguished by the divergence between their basic principles and between the elements in politics on which they lay most stress. We have seen how the pluralists asked what was the function of government, what purposes the state in particular among all other associations was alone or best fitted to achieve. This question is the way in which the problem has been seen by the English tradition from Hobbes through Locke and J. S. Mill; and it is on the whole characteristic of British and American thought to look at government in this practical and utilitarian light.

First, government is needed to provide security of life, as Hobbes insisted. No individual is strong enough to guarantee his own security unaided. No voluntary association is sufficiently inclusive or wields the sort of weapons needed to keep violence at bay. But security of life is not all that men need. Security of other interests (especially property, said Locke) and security from all kinds of damage by blackmail, arson, rape, assault, etc. (this was Mill's view) require government action. This is the field of criminal law. The Communist says that the state will wither away at the establishment of a classless society; but Marx and Engels nowhere explain what is to be done about crimes of violence. Lenin does face this problem in one place; he says:

We are not utopians, and do not in the least deny the possibility and inevitability of excesses on the part of *individual persons*, or the need to suppress *such* excesses. But, in the first place, no special machine, no special apparatus of suppression is needed for this; this will be done by the armed people itself, as simply and as readily as any crowd of civilized people, even in modern society, interferes to put a stop to a scuffle or to prevent a woman from being assaulted (V. I. Lenin, *The State and Revolution*, ch. 5, sec. 2, in *Lenin, Selected Works*, vol. ii, pt. i, pp. 293-294, Lawrence and Wishart, London, 1951).

But crowds do not part combatants and men do not violate women when there is a crowd standing by. Lenin's recipe is lynch law, and lynch law is notoriously incapable of dealing with most crimes or of dealing justly with those which it does assail. Here then is a clear case for government action.

Secondly, government is required to settle disputes which are not amenable to direct compromise or agreed settlement. This is the province of civil law. If government were to wither away, the victory in every dispute would go to the stronger or to the possessor. Things would be little better if a voluntary society undertook to adjudicate, for some disputants would not fall under its authority, nor could it enforce its awards.

These two functions of protection and of settlement of disputes exhausted the functions of the state as seen by the classic English tradition. Here the work of government is essentially negative: its force is applied only against bad men or against the side in a dispute which has the weaker case; and its only duty to the good and peaceable citizen is to leave him alone, except to the extent that it must tax him and perhaps enlist his services as jurymen or soldier to enable it to perform its protective and arbitral functions.

The Socialist View.—English and American governments up

to the middle of the 19th century restricted themselves to those minimal negative protective functions. But they performed two jobs which were the seeds of a more positive doctrine of state action. The state protected men's rights from invasion by other men. But there was one right for which it did more than that. On the Hobbes-Locke view, the state's concern with the right to life was to prevent other men at home or abroad from endangering my life. But what if my life is endangered by starvation (not because an ogre has shut me in a dungeon but because I cannot work or cannot find work to do)?

On the strict liberal or protective view, governments should agree with Arthur Hugh Clough:

Thou shalt not kill, but need'st not strive
Officially to keep alive.

But in fact government did so strive, through poor relief and casual wards. Over no other right did government assume this paternal care, but this is obviously the thin end of a very thick wedge. The "right to work" was originally taken to mean the right to do whatever work I can find (and to stop doing it) without interference; and this was how the right was interpreted and protected by English law. But what of the unemployed? Unemployment pay ensured their right to life, not their right to work. It is only since the state undertook the provision of schemes of work and adopted a full-employment policy that the supply of work has been accepted as a government responsibility.

The first seed in fact grew into the welfare state. Not only life, but education, health and pensions have become government responsibilities. It might be thought that there can be no limit to this extension, and the phrase welfare state encourages this idea. But even its strongest supporters would not propose state-guaranteed supplies of tobacco, cosmetics, television sets or theatre seats. "To each according to his needs"—not his wants—is the socialist slogan: the state should ensure the supply of those things from which, it is thought, no human being should be debarred by accident of birth or wealth or dwelling place. The welfare state really appeals to a principle of justice, not of welfare—to the view that it is unfair that some men should be deprived of things without which life is not worth living (health, education, work) because they cannot afford them.

Though the welfare state is not usually extended to supply luxuries there is sometimes invoked another principle, in addition to that of justice, which would work in that direction. It is the principle of equality—not merely equality of opportunity (which the principle of justice achieves) but an equality more fundamental still. It is thought wrong that some people should have automobiles, television sets or vacations which others cannot have. On this principle the aim of state education is not merely to provide educational opportunities for those who cannot afford them but to equalize education for all. The aim of taxation is not merely to raise money for necessary and justifiable services but to redistribute and to equalize incomes. It is held to give a child an unfair advantage not only if other children have no education but also if he has parents who can afford to send him to a better school or if he has the ability to pass examinations earlier than other children.

The second seed of a theory much wider than the negative liberal one to be found in 19th-century government was the postal service. For here was the idea that a certain service was required which could not be effectively supplied to all who needed it unless it was supplied by government. This seed has grown into the program of nationalization. This program too has tended to operate on a distinction between needs and wants. There are some services which every citizen in a civilized community has a right to enjoy: roads; drainage; and a clean water supply. All of these used to be supplied by individual enterprise or by private persons or companies working for profit. But this meant that many poor people or people living in remote areas could not have these services or had to pay a prohibitive price for them. But the list has grown to include railways, gas and electricity, where it is more doubtful whether these are needs to which all men have an equal right and which must therefore be state-supplied. We noticed above how the principle of justice was supplemented and in places

supplanted by the principle of equality. Here too another basic principle has come in to promote the development of state services: the principle that no man's labour should be exploited for the profit of another man, or, put the other way round, that no man should enjoy income unearned by his own efforts. On this principle there are no limits to nationalization as an ideal, since whenever any industry is nationalized the employment of labour for profit is correspondingly diminished; it ceases to matter whether services nationalized are necessary for civilized existence or whether the nationalization benefits the workers or the public.

The Conservative View.—In opposition to the liberal and socialist principles, it has been objected that they overemphasize human reason. No citizen regards his state in this cool, calculating way as an association existing to do certain jobs for him. "The state ought not to be considered as a partnership agreement in a trade . . . to be taken up for a little temporary interest or to be dissolved on the fancy of the parties" (Edmund Burke). To regard the moral claims of one's country in this light is like doing one's best for one's friends or one's children solely from a lively expectation of favours to come. Around these centres—country, family, friends—gather a loyalty and a devotion, traditions of fellowship and service which mere utility can never explain or exhaust.

Nor is reason an adequate guide for the rulers either: no human individual or committee can be trusted to change a society or to plan its future. The garnered wisdom of centuries expressed in custom, tradition, laws and constitutions, the slow process of unconscious change, adapted perhaps empirically here and there to some immediate problem—these form a better guide than the blue books and blueprints of the planners. The conservative tradition respects the individual, not the abstract identical individuals of liberal theory, the bearers of universal rights, but the individual in his rich variety. It would rather have things done in an illogical, confused and piecemeal way, provided that this allowed individual variety and individual enterprise, than in an efficient, streamlined way through uniform leveling and dragooning. It sees state provision and state management in human terms. State or "free" education means education at the taxpayer's expense. It will not deny occasional justice to the Robin Hood ethic of robbing rich Peter to pay poor Paul, but it will require strong justification for it in each case. It sees state control as control by politicians and civil servants. Such control, the conservative would say, may on occasion be justified but there is no such inherent merit in it as to justify rejoicing in its every advance, as the nationalizers do.

Politics and Morals.—The aim of the preceding sections has been to show how political ideals rest on certain moral principles or judgments of value. To work out these connections is the task of political philosophy. But it may be doubted whether it is the task of political philosophy to decide between these principles or the systems erected upon them. Here political thinking is driven back on a fundamental issue in ethics. Some would hold that moral values are subjective: each man must make his own decision between them; none of them can be rationally defended against its rivals. If so, political philosophy cannot claim to do as it once did, to lay down the best kind of state or the best laws.

Analysis.—Developments since the middle of the 19th century have thus tended to diminish the function of political philosophy. Factual questions have been removed from it and handed over to sociology and to psychology. Its nonfactual arguments have been driven back into ethics, and ethical principles in their turn have been removed from the field of rational discussion. By the middle of the 20th century, however, philosophical movements were showing a great positive interest in linguistic analysis, and here, it would seem, there was another remaining field for political philosophy. The analysis of language about politics, of such terms as government, sovereignty, law, rights and punishment, remained to be achieved.

POLITICAL SCIENCE, a term most broadly understood to mean the systematic study of government processes by the application of scientific methods to political events. More narrowly, and more traditionally, it has been thought of as the study of the state and of the organs and institutions through which it functions. In the United States, as in most countries, political science is thought to be a single discipline, but the plural form is used in France, as in the name of L'École Libre des Sciences Politiques, founded in 1871, the first school of its kind in Europe. There is some tendency both within and without the United States to be agnostic about the scientific character of the discipline, which is sometimes referred to as "political studies." Although speculation about political subjects is not unknown in other ancient cultures, such as that of India, most students agree that the roots of political science are to be found in the earliest sources of western thought. Sir Frederick Pollock wrote of Aristotle that "he has been recognized as the founder of political science by the general voice of posterity."

The origins of contemporary political science are to be found in the 19th century's enthusiasm for the development of social sciences, an enthusiasm that had been stimulated by the rapid growth of the natural sciences. This enthusiasm reinforced an existing interest in the subject in the United States and created a generation of U.S. political scientists, including Theodore Dwight Woolsey, John W. Burgess, Woodrow Wilson, W. W. Willoughby, and Frank Goodnow. In 1903, to signalize the professional nature of the new political science, the American Political Science Association was organized with Frank Goodnow as its first president.

Although the study of political science in U.S. universities and colleges surged in the last half of the 19th century, attention to systematic politics had been by no means unknown before that, although the subject was usually taught in conjunction with moral philosophy. At Harvard College, under Henry Dunster, its first president, the curriculum in 1642 provided instruction on Mondays and Tuesdays in "*Ethicks* and *Politicks*, at convenient distances of time." Politics as an academic subject was made independent of moral philosophy when Theodore Dwight Woolsey, president of Yale University (1846–70), first introduced a course in "political philosophy" in 1847–48. The first chair of history and political science was created at Columbia University in 1857 and was occupied by Francis Lieber, who had earned a reputation as a political philosopher while teaching in South Carolina. Political science, free of any connection with moral philosophy, fusion with history, or submergence in political economy, may be said to date from 1880 when John W. Burgess, after studying at L'École Libre des Sciences Politiques, succeeded in establishing a separate school of political science at Columbia University. Although political science faculties appeared in increasing numbers after 1900, the growth was uneven and in some major institutions separate departments were not created until after World War I. In England, the emergence of political science as a subject was recognized in the establishment of the London School of Economics and Political Science in 1895 and by the founding of a separate politics chair at Oxford in 1912.

Though political science may be distinguished from political philosophy, the distinctions must be unsatisfactory inasmuch as they lack categorical rigour. In the most usual distinction, political philosophy is thought to be concerned primarily with the study of political ideas, often within the context of their times. It is strongly normative in its thrust and disposition, and rationalistic in its method. Political science, to the contrary, concerns itself with institutions and behaviour, eschews normative judgments as much as possible, and attempts to derive principles from objective facts with as much quantification as the evidence will allow. Thus political philosophy speculates about the place and order of values, the principles of political obligation—why men should or should not obey political authority—and the nature of such terms as "right," "justice," and "freedom." Political science, on the other hand, seeks to establish by observation (and, if possible, by measurement) the existence of uniformities in political be-

haviour—how governments and people in political situations actually conduct themselves—and to draw correct inferences from these data. The stated differences between political philosophy and political science are less than is sometimes supposed, for the most empirical scholar in both the social and natural sciences makes use of unproved postulates, hunches, and intuitions; and the most rationalistic philosopher employs conceptions that embody empirical statements.

Because political science deals with some aspects of human behaviour, it is closely allied to other social sciences that also deal with human behaviour. For example, numerous theories of the state have drawn inspiration from the human being as model, as in the *Policraticus* of John of Salisbury (1159) in which the physiology of the body and that of the state are compared; or in the *Republic* of Plato in which the elements of the human personality prefigure the class structure of the state; or in Rousseau's *Contrat Social* in which the political order is animated by a *General Will* (will being a human attribute); or in the work of Hegel in which the state is exalted as a person.

Besides biological and psychological theories of the state, there have been anthropological theories like that of Gumpłowicz, which ascribes the origin of the state to the struggle of races for domination, and those of De Gobineau and Houston Chamberlain, which assigned primacy in politics to a master race. Economic theories of the state are to be found in Harrington's *Commonwealth of Oceana* and in the works of Marx and Lenin. Sociological theories of the state are available in Pareto's *Mind and Society* and Karl Mannheim's *Ideology and Utopia*. Sociological theory with a core of geographical determinism led the Swedish political scientist, Rudolf Kjellén, to a theory of politics which he named "geopolitics." Cybernetics supplies a modern model for the study of political systems as communications networks, resembling that of the brain and the nervous system in the human body.

Among the other social sciences with which political science has been historically related, a special place is occupied by law. A close connection between the state and law was made in the 16th century in Jean Bodin's theory of sovereignty, which supposed the necessary existence in each state of a supreme authority to make the law. This theory gave rise to numerous juristic theories of the state, especially among German publicists of the 19th century who sought to define the nature of federation and empire. Although the doctrine of sovereignty made most sense as a statement of the power of monarchs to make the law in simple unitary political systems, earnest writers forced the facts of federation and empire to fit the theory, and often ignored those that did not.

The relatively narrow and somewhat culture-bound view that the state is the focus of political science has been questioned by some scholars who feel that the concept has limited analytical use. For some of these, the subject matter of political science is power in human relations, a phenomenon that may be studied in forms of human association other than the state, and with somewhat better claims to the attribute of universality, which is one of the elements of science. G. E. G. Catlin, an English scholar, in his *Science and Method of Politics* has expressed this view. Bertrand Russell, the English philosopher, and Bertrand de Jouvenal, the French writer, have contributed to the literature on political power; and Harold Lasswell, the American political scientist, has brought to the analysis of power strong supporting insights from the field of psychology.

The inadequacy of mere institutional description and the failure of ethnocentric categories to be truly comparative have led still others to employ such various definitions of the research field as political process, decision-making, community studies, and political systems. For those interested in political process as the significant research situation in political science, a principal analytical technique has been the group concept derived most directly, in U.S. political science, from Arthur F. Bentley's *Process of Government* (1908), and reinforced by contributions from sociology. This has led to an increasing understanding of interest groups in the political process, an understanding which has been enriched since World War II by new research by scholars in England, Yugoslavia, and Australia. Research into decision-making uses the

techniques of game theory (see GAMES, THEORY OF); and the investigation of political systems has been greatly stimulated by the rise of former colonies to independence. It has also been suggested by some that political science is one of the "policy sciences" and that its proper concern is the objective selection of alternative public policies according to consequences predicted for them by the political analyst.

The question as to whether political science is a "science" is largely inconsequential because the problem is primarily one of definition. If the term science is to be applied to any body of systematically organized knowledge based on facts found by empirical methods with as much measurement as the material allows, then political science is a "science," just as are the other social disciplines. If, on the other hand, the term science is to be limited to those disciplines in which the scholar can control the materials to be studied, can perform experiments that others can reproduce under the same conditions, and in which predictability is possible, then the label is less appropriate, although not entirely misapplied. Thorstein Veblen denied that political science was anything more than a "taxonomy of credenda," but Lord Bryce, although of the opinion that politics could not be as precise as mechanics, said, in his presidential address to the American Political Science Association in 1909, that it was at least as much a science as meteorology.

The method of political science varies with the subject matters that make up the topics of the discipline. Thus institutional analysis is conventional in the study of the formal agencies of government; structural-functional analysis which was developed by sociologists has been employed in the study of the political systems of non-Western countries; and the methods of legal reasoning are those customarily brought to the study of international, constitutional, and administrative law. The techniques of statistics are applied to the measurement of public opinion and the voting activities of the electorate, and some attempt has been made to apply them to the study of the behaviour of courts and judges. The techniques of historical analysis and of conceptual inquiry are principal approaches to political philosophy and theory. Other subjects of political science using combinations of all of these techniques are public administration, state and local government, political parties and interest groups, governmental regulation of the economic order, and international relations and politics.

Although political science is primarily an academic discipline, it has applications in the government service, journalism, business enterprise, and professional politics. Political scientists have been called to advise on the size, shape, and staffing of governmental agencies, the design and installation of public administration programs, the behaviour of ethnic, social, and economic groups, the analysis of policy alternatives in national security and other public affairs, the refinement of principles of constitutional and administrative law, the establishment of the optimum conditions for new governments such as those of Puerto Rico or Japan or West Germany, the development of governmental programs for the regulation of business enterprise, and the prescription of rules for the more efficient conduct of the business of legislative bodies.

Though empirical approaches to the study of political events have been more widely used in the United States than elsewhere, significant work has been done in several countries. In France, where constitutional law and history have been abundant and politics often has been viewed from legal perspectives, André Siegfried introduced the geographical and historical study of elections as early as 1913, and Jean Stoetzel the scientific study of public opinion in 1943. The latter was not a field study but a discussion of method. In the field of political parties the work of Maurice Duverger and François Goguel has been notable. England has made many creative contributions to political theory and law throughout its history, as have other European countries, and it has also produced substantial work that can be classified as positive political science. Among these are the studies of R. T. McKenzie and David E. Butler in the field of political parties, S. E. Finer on interest groups, Uwe Kitzinger on German elections, and Herman Finer and Denis Brogan in the field of comparative government. Early work by Graham Wallas drew attention to

the importance of psychology in an understanding of politics. In Australia, teaching and research in political science have developed in the years since 1945. Strong interest has been shown in parties and elections, and attention has been given to the study of interest groups. (E. LA.)

POLITIS, NIKOLAOS SOKRATES (1872–1942), Greek jurist and diplomat, a brilliant champion of the peaceful settlement of disputes and of disarmament, was born at Corfu on Feb. 7, 1872. After holding professorships in the faculty of law at Aix-en-Provence, at Poitiers, and at Paris, he was in 1914 summoned by Eleutherios Venizelos to reorganize the Greek Ministry of Foreign Affairs, of which he became director general. Appointed minister of foreign affairs in 1916, he went to the peace conference of 1919 as the delegate of Greece. In the League of Nations, where he was also the Greek delegate, he wrote the report on the Geneva Protocol (1924). As vice-president of the Disarmament Conference, he drew up the definition of the aggressor there propounded. His lucid, powerful, and eloquent speeches put him in the first rank of the delegates to the League.

Politis published a number of books of jurisprudence, including *La Justice internationale* (1924) and *Les Nouvelles Tendances du droit international* (1927; Eng. trans., *New Aspects of International Law*, 1928). These showed him to be at once a thinker of far-reaching interests and a passionate believer in the future of international law. The foundation of the Academy of International Law at The Hague was largely the result of his efforts. In 1937 he was made president of the Institute of International Law. He died at Cannes, France, on March 4, 1942. (CH. D. V.)

POLK, JAMES KNOX (1795–1849), 11th president of the United States, was born in Mecklenburg County, N.C., on Nov. 2, 1795. At the age of 11 he accompanied his family to Tennessee, settling in what is now Maury County. In his childhood formal schooling was impossible because of ill health, but at the age of 20 he successfully passed the entrance requirements for the second-year class of the University of North Carolina. As an undergraduate his record was "correct, punctual, and industrious." As a graduating senior in 1818 he was the Latin salutatorian of his class—the pre-eminent scholar in both the classics and mathematics.

Early Career.—With this academic background he began to read law in the office of Felix Grundy in Nashville, Tenn., to associate with leading public figures in the state, and to make political speeches. In 1820 he was admitted to the bar. Since he was a confirmed Democrat and an unfailing supporter of Andrew Jackson, and since his style of political oratory became so popular that he was characterized as the "Napoleon of the stump," his political career was assured. With him in his rapid rise to political power was his wife, Sarah Childress Polk (1803–1891), whom he married Jan. 1, 1824, during his service in the state house of representatives (1823–25).

Mrs. Polk's home was Murfreesboro, Tenn., the temporary state capital. The social prominence of her family and her personal charm were distinct assets for a politically ambitious lawyer. As an official hostess she won the admiration and esteem of the leading figures of the day. For 25 years she was her husband's close companion in state and national politics. In the long period of her widowhood she maintained Polk Place in Nashville as a shrine.

James K. Polk was by nature a student of government, by experience a legislator and by force of circumstance an administrator. He was not an easy man to know or to like. Boon companions did not relish his austerity. Associates tolerated but did not approve his inflexible living standards. He had many acquaint-

ances, but very few friends. One friend was Andrew Jackson, who encouraged and advanced Polk and whose influence carried him from the Tennessee house of representatives to the U.S. house of representatives, where he served from 1825 to 1839. From 1835 to 1839 he was speaker of the house. In that service in Washington Polk acquired a reputation as a constant, undeviating supporter of Jacksonian principles. In 1839 he left the house to become governor of Tennessee. Two defeats for a second term (1841, 1843) by small majorities convinced him that to strengthen his party he should return to Washington in some capacity.

Polk's nomination for president at Baltimore on the Democratic ticket in 1844 was unsought by him, for the party had more prominent sons in Martin Van Buren, Lewis Cass, and James Buchanan. However, they could not reconcile their differences and a compromise candidate had to be found; since the campaign was to be run on issues and not on personalities, it was decided that Polk would do. He is regarded as the first "dark horse" nominee in the history of the presidency. He was a party man from the west, and his experience as a legislator, it was thought, would make possible the realization of legislative and executive co-operation and understanding in the functioning of the national government. While speaker of the house he had decided many procedural questions and had usually been sustained on appeal by majorities composed of the leaders of both parties. His party feeling was intense, but his integrity was unquestioned. He knew the rights and privileges of the house and he also knew its responsibilities.

Campaigner Polk surprised the country by taking a positive stand on two burning issues of the day. While other candidates hedged on Texas, he demanded annexation. While other candidates evaded the Oregon problem he openly advocated a drastic change in policy in the boundary dispute with Great Britain represented by the slogan "54°40' or fight." His election was close, but it was decisive—a popular plurality of about 38,000 and 170 electoral votes against 105 for Henry Clay.

Presidency.—Not yet 50 years of age, Polk was the youngest successful presidential candidate up to that time. He entered the presidency full of vigour and with an expressed zeal to serve his country to the best of his ability. He left it four years later exhausted and enfeebled by the efforts he had made. In office he demonstrated remarkable skill in the selection and control of his official advisers. In his formal relations with congress his legislative experience served him well. When his party was united, he yielded to the wishes of congress. When he disagreed with congressional policy and made an issue of it, he fortified his position with recognized precedent and established practice. His formal disapprovals (two message vetoes and one pocket veto) were questioned, but the two returned measures failed to command the necessary two-thirds majority for repassage.

The Polk administration was marked by large territorial gains. The annexation of Texas as a state of the union was concluded—resulting in a two-year war with Mexico. As a consequence of that war the southwest and far west (California), by conquest and by purchase, became part of the U.S. domain. During this period the northwest boundary became fixed by treaty, and the continental United States emerged a recognized reality. Additional achievements included a treaty with New Granada (Colombia) clearing up the problem of right of way for U.S. citizens across the Isthmus of Panama; establishment of a warehouse system which provided for the temporary retention of undistributed imports; and the passage of the Tariff Act of 1846. As these helped foreign trade, so the reenactment of the independent treasury system helped in the solution of domestic financial problems.

The expansion of the country westward caused the creation of a new agency, the Department of the Interior. The Polk administration should also be credited with the establishment of the U.S. Naval Academy at Annapolis, Md., and the authorization of the Smithsonian Institution.

Polk's influence over his congresses may be gauged from the results of the recommendations of four annual messages and ten significant special messages to one or both houses. His control of legislative policy in bitterly partisan congresses must be judged

BY COURTESY OF THE LIBRARY OF CONGRESS
POLK, DAGUERRETYPE BY MATHEW
BRADY

in terms of results, not oratory or parliamentary delay. He recommended with a high degree of success: settlement of a trade dispute with Great Britain; an increase in U.S. armed forces; war with Mexico; peace with Great Britain over Oregon, making available finances to expedite peace conclusions; organization of the Oregon Territory; peace with Mexico providing for limited conquest; and a revised treasury system. As an executive he refused information desired by Congress (on the ground that it was incompatible with the public interest), recognized a new French revolutionary government, and proclaimed the validity of the Monroe doctrine. These pronouncements were recognized by succeeding presidents.

The diary kept by Polk during his term of office stressed the presidential burden. Day after day, week after week, he recounted in his diary his experiences with the hosts of office seekers who infested Washington and who occupied so much of his public time. Again and again there was evident a note of despair in his writings. He knew from personal experience what an evil an unlimited executive patronage can become. Nevertheless, he felt powerless to change its obligations and too conscientious to avoid its duties. At the close of his term, March 4, 1849, Polk retired to his home in Nashville, where he died on June 15, 1849.

The office of chief executive under Polk was well filled. He maintained it with dignity, with integrity, and with an extraordinary sense of duty. His great influence over congress was due to the justness of his policies and the persistence of his efforts in having the members see the questions not as interests of district or section but as matters of national welfare. It was his sturdy character and unblemished reputation that gave weight to his counsels and strengthened his pleas. History may not rate James K. Polk as one of the greatest of U.S. presidents, but for the accomplishments of his short time in office he cannot be rated among the least influential.

Polk, 1845-1849* (1910), an almost complete printing of the manuscript material and a revelation of the mind of a president; E. I. McCormac, *James K. Polk: a Political Biography* (1922); C. G. Sellers, *James K. Polk, Jacksonian, 1795-1843* (1957). (G. C. Ro.)

POLKA, a lively dance in 2/4 time of Bohemian origin, characterized by three quick steps and a hop. Introduced in Paris about 1843, it became an extraordinary craze in the ballroom and on the stage, sweeping rapidly across Europe and the United States. Frequently introduced in ballets, such as F. Ashton's *Façade*, it has also retained considerable popularity as a social dance.

(LN. ME.)

POLLAIUOLO, the name of two Florentine brothers, Antonio, who was a sculptor, painter, engraver, and goldsmith, and Piero, who was a painter and sculptor.

ANTONIO POLLAIUOLO (c. 1430-1498) was trained by his father as a goldsmith, and his most outstanding work in this field is the base for the silver reliquary of St. Giovanni (1457-59, now in the Opera del Duomo, Florence). Yet his chief claim to fame rests on his works in bronze, such as a lively small group of "Hercules and Antaeus" (Bargello, Florence), which once belonged to the Medici. Called to Rome in 1484, he executed with the assistance of his brother the lavish bronze tombs of Pope Sixtus IV (now in the SS. Grotte of St. Peter's) and of Innocent VIII (St. Peter's). The latter, with the enthroned figure of the pope giving his blessing, had a considerable influence on later papal tombs. It seems that Antonio learned the technique of painting from his brother and completed a number of pictures in collaboration with him, among them the altarpiece in the chapel of the cardinal of

ALTINARI

Portugal in S. Miniato, Florence, and the "Martyrdom of St. Sebastian" (National Gallery, London). Antonio's chief interest was the human figure in motion; he is supposed to have been one of the first artists to concern himself with dissection and anatomical studies. Hence his engraving "Battle of the Nudes" as well as his drawings took for his and later generations the place of pattern books. He died in Rome on Feb. 4, 1498.

PIERO POLLAIUOLO (1443-1496), born in Florence in 1443, was probably a pupil of Alessio Baldovinetti. He painted six of the "Virtues" for the Mercanzia of Florence (1469-70, Uffizi, Florence). His principal work, "Coronation of the Virgin," was painted for S. Agostino, S. Gimignano (now in the cathedral). He died in Rome in 1496.

POLLARD, ALBERT FREDERICK (1869-1948), English historian of the 16th century, was born at Ryde, Isle of Wight, on Dec. 16, 1869, and was educated at Felsted School and Jesus College, Oxford. In 1893 he was appointed to the editorial staff of the *Dictionary of National Biography*, to which he contributed about 500 entries. During that period he wrote one of his biographical volumes, *England Under Protector Somerset* (1900). Quitting the *Dictionary of National Biography* in 1901, he was elected to the chair of constitutional history at the University of London in 1903; he held that position until his retirement in 1931. At the University of London he firmly established the history degree course and strove to promote postgraduate research. The Institute of Historical Research, of which he was chairman (1921-39), was largely his achievement. He was the leading Tudor scholar of his day; his volume in the *Political History of England* series and his books on *Henry VIII* (1902) and *Wolsey* (1929) were models of careful and enduring work. He died on Aug. 3, 1948, at Milford-on-Sea, in Hampshire.

POLLEN COUNT, an estimate of the concentration of pollen grains in the air, gives some indication of the relative discomfort that may be experienced by sufferers from hay fever and allergenic asthma. The count is based on the accumulation of pollen grains on a collection device (grease-coated microscope slide, cellophane tape, etc.) during successive 24-hour periods (although spot checks are often also made). The collected grains are viewed under a microscope for identification and counting, the count being given in grains per cubic metre of air. The pollen count is higher during the day; it is highest during dry, windy weather and lowest after a rainfall. See also HAY FEVER; ASTHMA.

POLLEN GRAINS. In the biology of the plant, pollen grains are the structures that produce the male sex cell (sperm), which in turn effects bisexual reproduction by union with the female sex cell (egg). In the evolution of higher plants pollen grains are derived from asexual reproductive structures called spores, and in certain groups of plants, both living and fossil, the distinction between pollen and spore is arbitrary since they both perform a similar function in reproduction. The term pollen is usually restricted, however, to the male reproductive structure of seed-bearing plants, including the gymnosperms—conifers, cycads, ginkgo, etc.—and the angiosperms—all the flowering plants. Genetically the pollen grain is a minute plant, the cells of which bear one-half the chromosome number (the haploid number) found in the parent plant (which has diploid cells). Botanically the pollen grain is the male counterpart of the haploid female embryo sac in the ovule, the potential seed.

Transfer of pollen is carried out by wind, water, insects and other agents. After a pollen grain has made contact with the female reproductive structure—the moist stigma of the pistil—it sends out a pollen tube, which travels down through the pistil and into the ovules, within the ovary. The pollen tube works into the ovule and fertilizes the egg cell within the embryo sac. After fertilization the ovule begins to develop into a seed. (For further details on pollination see POLLINATION.)

The role of pollen grains in the reproduction of plants was known empirically to several ancient cultures. The earliest is

PHILIP FEINBERG—FELLOW OF THE NEW YORK MICROSCOPICAL SOCIETY

PHOTOMICROGRAPHS OF POLLEN GRAINS: (LEFT) DAY LILY MAGNIFIED ABOUT 65 TIMES; (RIGHT) PINE MAGNIFIED ABOUT 400 TIMES

perhaps that of the Assyrians, who employed hand pollination to ensure full yields of date palm fruits. Since pollen grains are minute in size—although produced in prodigious numbers in some plants and therefore visible as a dust—knowledge of their structure and details of their biologic function awaited the discovery of the microscope. The early microscopists Nehemiah Grew and Marcello Malpighi studied and drew pollen grains.

Because of their remarkably symmetrical structure and surface patterns pollen grains are readily recognizable under the microscope. The structure of the wall of a pollen grain is oftentimes so characteristic that in some cases species may be identified by pollen grains alone. On the other hand there are cases in which pollen grains of very like structure occur in quite unrelated plant families.

Because of their high resistance to decay, their widespread dispersal by wind and water and their abundant production by plants, pollen grains are very common constituents of geologic sediments, both recent and ancient. In view of these features pollen grains have provided much information on the origin and geologic history of terrestrial plant life (see PALYNOLOGY).

Pollen is produced in such quantities that it is a significant component of the airborne constituents of the earth's atmosphere, especially in areas over continents. The proteinaceous substance in many pollen grains (namely, ragweed and many grasses) induces an allergic reaction commonly known as hay fever (*q.v.*). See also references under "Pollen Grains" in the Index.

POLLENTIA (mod. POLENZA), an ancient town in the territory of the Statielli in Liguria, northern Italy, 10 mi. N of Augusta Bagiennorum (Vagienna) on the Tanarus (Tanaro) River. Its position on the road from Augusta Taurinorum (Turin) to the coast at Vada Sabatia (Vado), where a road diverged to Hasta (Asti), gave it military importance. Decimus Brutus managed to occupy it an hour before Mark Antony in 43 B.C.; and it was there that Stilicho on Easter Sunday, April 6, A.D. 402, fought the battle with Alaric which, though indecisive, led the Goths to evacuate Italy. Pollentia was noted for its pottery and wool. Remains survive at the village of Polenza. (H. H. Sp.)

POLLINATION, a botanical term for the transference of pollen, the dustlike powder produced by the stamen of seed plants, to the stigma (the receptive surface) of the ovary of the flower. (See also FLOWER; POLLEN GRAINS.) Pollination brings about the fertilization of the ovules in the ovary and their subsequent development into seeds. As the pollen-bearing parts of the stamens are rarely in contact with the stigma at the time when both of these are ripe, usually wind or insects, though sometimes other agencies such as water or birds, bring the pollen to the stigma. The great variety in the form, colour and scent of flowers was

developed in relation to the particular agency of insects. Apart from the mechanism of pollination we can distinguish two types—self-pollination, in which pollen is transferred from anther to stigma in the same flower or between flowers of the same plant; and cross-pollination, in which pollen is transferred from an anther on one plant to a stigma on another plant, whether of the same species or not, and whether done by wind, insect, hummingbird, or man.

Cross-Pollination.—Cross-pollination is the only possible method in the case of unisexual flowers because these flowers have only stamens or pistils, not both. In hermaphrodites, *i.e.*, in flowers bearing both stamens and pistils, either self-pollination or cross-pollination can occur. It is interesting to note, however, that many flowers have special arrangements to ensure that the pollinating mechanism, whatever it may be, allows cross-pollination and not self-pollination. One of the commonest methods to achieve this is a separation in time of the sexes—the stamens burst and shed their pollen either before or after the stigma is receptive. This separation in time—and it may apply to the separate male and female flowers on the same plant—is known as dichogamy. When the stamens ripen first it is known as protandry, the more common case; when the stigma is ready first, it is known as protogyny. Protandry is very common in insect-pollinated (entomophilous) flowers, as in nearly all members of the Compositae (*q.v.*) and Umbelliferae, many Labiatae (such as dead nettle [*Lamium*] and *Salvia*), the Caryophyllaceae, the great willow herb (*Epilobium angustifolium*), etc. Protogyny is found in the horse chestnut (*Aesculus*), the autumn crocus (*Colchicum*), many Araceae, and in wind-pollinated (anemophilous) flowers such as plantain (*Plantago*), meadow rue (*Thalictrum*) and many grasses, though here separation in time is very short and many are self-pollinated, such as wheat, barley and oats.

Another structural feature that is a bar to self-pollination is heterostyly. It is seen at its simplest and clearest in the primrose. About half the population of this plant has flowers with long styles, which bring the stigmas to the mouth of the corollas as little "pinheads." The stamens lie halfway down the tubes. In the other half the style is short and the stamens form a "thrum-head" at the mouth of the corolla. Visiting bees transfer pollen from one type of flower to the other. An equal balance of the population is maintained by a special genetic system. Species of *Linum*, *Oxalis* and *Lythrum salicaria* (loosestrife) are other examples. The most complete bar to self-fertilization is self-sterility, which is known to be widespread. This condition is brought about by failure of the pollen tube to grow properly on styles of the same plant, though it can do so on styles of most other plants of the species.

Cross-pollination gives two distinct results, one short-term and the other long-term. It tends to give more and better seed and more vigorous progeny—a result well known in the production of outbred maize. The long-term effect is on the process of evolution. Crossing maintains and replenishes the pool of mutations, patent and latent, on which natural selection acts. Crossing also brings about new combinations of mutations. It has a major effect on the rate at which species can evolve.

INSECT POLLINATION (ENTOMOPHILY)

The special characteristics of entomophilous flowers are the attractive colour of the floral envelope, the presence of scent and of nectar, and of pollen that is not powdery but sticky and is present in comparatively small quantities. The entomophilous is the most common type of pollination in flowering plants, and special floral conformations and irregularities adapted to insect visitors are characteristic of the higher families of flowering plants, as will be seen below. The evolution of flowers and of insects must have gone hand in hand; such groups as Lepidoptera (butterflies and moths) and Hymenoptera (bees, wasps, etc.) could not have existed without the more elaborate and honey-bearing flowers. The plants with such elaborate flowers are cross-pollinated only by insects with highly specialized organs for sucking nectar and gathering pollen.

Types of Insects.—Five classes of insects visit flowers. The

HERMANN EISENBEISS

INSECT POLLINATION OF SALVIA GLUTINOSA

(A, B, C) Honeybee triggering the mechanism; (D) corolla removed from flower to show details. Arrows indicate force upon and reaction of parts

Hemiptera (bugs) are unimportant. The Coleoptera (beetles) are frequent visitors, eating pollen and licking nectar with short tongues. The Diptera (flies) are important and varied visitors; many have only short tongues but some, e.g., the hoverflies, are moderately long-tongued and suck concealed nectar. The Hymenoptera include the most important flower visitors. Many bees have long tongues and can manipulate complex floral mechanisms. The Lepidoptera are also important visitors. They include the longest-tongued insects which alone can reach the most deeply concealed nectar.

Classes of Flowers.—The entomophilous flowers can be divided into nine classes based on the structure of the flower and its relation to particular insects.

1. Class A, flowers with exposed nectar: in this class come most Umbelliferae, many Saxifragaceae, the bedstraws (*Galium*), ivy, and such trees as maple, elder and linden. The flowers are wide open and usually small, and the visitors are mostly short-tongued.

2. Class AB, flowers with partially concealed nectar: in this class fall the buttercups, the Cruciferae, the strawberry and the willows. The nectar is protected and concealed by the position of the stamens, by the development of hairs or scales, or by the flower being partially tubular.

3. Class B, flowers with fully concealed nectar: in this class are the flowers of many Carophyllaceae, wild geranium, phlox, blackberry, eyebright (*Euphrasia*), mint, heather. In these the nectar may be concealed by the stamens, by the calyx, by the receptacle becoming hollowed or by the petals being united to form a sympetalous corolla. The insect visitors are the smaller bees and a few of the longer-tongued flies.

4. Class B' is an extension of Class B and includes the flowers of the Compositae, most Dipsaceae and some Campanulaceae, in which the flowers have the same length of tube, etc., as Class B, but are in clusters.

5. Class F, lepidoptera flowers, includes those flowers in which the floral tube is so deepened that in many cases only Lepidoptera can reach the nectar. The alpine moss campion (*Silene acaulis*), for example, is adapted to butterflies, while the bladder campion (*Silene inflata*) is adapted to moths and emits a scent at night.

6. Class H, bee flowers, are those that are visited mostly by long-tongued bees, the depth of the tube being 6 to 15 mm. The flowers are also often markedly irregular, providing a landing place for the bee.

7. and 8. The D and K classes of flowers include those adapted to small insects; they are pollinated by flies, beetles and small bees.

9. Class Po, pollen flowers: these provide no nectar, but abundant pollen for which the flower is visited, mainly by bees. Examples: *Clematis*, *Spiraea*, rockrose (*Helianthemum*), dog rose (*Rosa canina*), poppy.

Food, Colour and Scent.—The insect visits the flower for nectar or pollen. Nectar is produced by special glands, the nectaries, which may occur on any of the floral organs. In many flowers nectar collects at the bottom of the corolla tube or in a special spur. It is a solution of the sugars glucose, fructose and sucrose at a concentration ranging from 8% to 70%. Pollen is rich in proteins and oil.

It seems obvious that scent and brightness must be the guides for the visiting insect. Whether the insect perceives colour as

such or only brightness was long in doubt, as were the details of its reactions. Exact knowledge dates from the work of K. von Frisch, begun in 1914. He studied the special senses of the honeybee, a domestic animal that lends itself to controlled experiment. The bees of a hive can be trained to visit a piece of blue paper with a watch glass of sugar water on it. They continue to visit the paper for a time after the sugar is removed. This fixation is the basis of the bee's habit of mass visits to one type of flower in nature. Moreover, the bee can pick out the blue paper from a series of graded grays, some of which must have the same brightness. It perceives blue colour as such. It also perceives white and yellow; but it cannot distinguish red from green, dark gray or black. It is significant that, where insect pollination is predominant, flowers show white, yellow, purple and blue colours, but very rarely red.

By other similar experiments, Frisch showed that bees can distinguish between scents in very much the same way as man can. The sense of scent is used by scout bees to inform their fellows in the hive of the kind of flower available for mass visiting. This extraordinary proceeding and the subject of the bee "language" lies in the domain of insect physiology.

F. Knoll carried out similar studies on other insects in the field as well as in the laboratory. He came to the conclusion that colour is the important "distant" signal for the bee and that scent is a "near" signal, which aids in the final selection of a flower. He studied the behaviour of one of the long-tongued flies, the bee fly (*Bombylius fuliginosus*), as it visited the flowers of the starch grape hyacinth (*Muscari racemosum*) in Dalmatia. It flew from one spike to another of this one species of flower. It would dip to a piece of blue paper placed between the plants, and could pick out blue from surrounding grays. It also visited yellow flowers. If a spike of flowers was covered by a clear inverted test tube the fly would approach and circle the tube but would not try the opening, a short distance removed, from which the strong scent welled out.

In another group the hummingbird hawk moth (*Macroglossus stellatarum*) also visits the grape hyacinth, perceiving its blue colour. At close quarters it is able to find the mouth of the corolla by perceiving the pattern of white petal tips on the blue ground. Here is a distant reaction to blue and a near reaction to white circle on blue ground. The same insect flies from a distance to the yellow flowers of the toadflax, perceives at close quarters a pattern of orange blotch on yellow and is able to probe the narrow entrance to the deep spur with great speed and accuracy, and while in flight. Such colour patterns are frequent in flowers; e.g., the dark streaks on pansy petals and the orange eye on blue ground of the forget-me-not. They are called honey guides. Their recognition is responsible for the accuracy with which insects probe sources of concealed nectar.

The hawk moth has a deficient sense of smell, but it is certain the night-flying moths perceive odours. J. H. Fabre showed that they can react to flower scents at a distance of more than 100 yd. Some flies and beetles react to stinks like that of rotten meat. Such odours are given off by the clubs of many aroids and the flowers of some asclepiads. The colour of these is often a dull red. In the case of the South European *Arum nigrum* (a close relation of *Arum maculatum*, the lords-and-ladies), Knoll showed that the insects reacted to the smell and not to the lurid colour.

In this curious plant pollen-dusted small flies and beetles slide down the slippery hood and are trapped by a fringing "wall" of hairs among the ripe female flowers. After a day or two the stigmas shrivel, the anthers open and release pollen, the stiff hair "wall" shrivels and the newly dusted insects escape.

The Form of the Flower and Floral Mechanisms.—The form and size of the flower and the degree of concealment of nectar determine the kind of insect visitor. The structure of the flower often imposes a particular course of visit that favours cross-pollination. There is very great variety of detail and the variety of structure gives the elegant range of floral form.

In the flowers of Class A the visits of small insects are haphazard. The small flowers of the hedge parsley (*Anthriscus sylvestris*) are showy in the massed umbel. The nectar is freely exposed on lobed nectarial disks in the centre of the corolla. Small flies and beetles lick the nectar and transfer pollen at random. But the stamens are withered before the stigmas are ripe, and cross-pollination is favoured.

The buttercup is an example of the more advanced flowers of Class AB. There is a nectary at the base of each petal and it is covered by a little scale. There is no definite manner of visit, but larger flies and small bees tend to settle on the centre of the flower where they touch the stigmas first. Willows are the earliest mass source of nectar in the spring, and are much visited by bees. The flowers are small and simple but are so close-set in their catkins that small insects cannot reach the nectar. They are dioecious; i.e., with staminate and pistillate flowers on different plants.

In Classes B, B', F and K are found the most elaborate examples of the relation of floral structure and insect visit. Some idea of the range is given in the following examples.

Sage.—Such a plant as the sage (*Salvia pratensis*) has a typical bumblebee flower. The bee alights on the platform formed by the lower lip of the corolla and pushes its head down the tube to reach the nectar at the bottom. Each of the two stamens is of special shape; the connective is very large and two-armed, and is hinged to the short filament. The longer arm bears a half anther and the short arm is sterile, the whole stamen having a lever mechanism. The bee, in probing for the honey, comes in contact with the short arm of the lever and in pressing this down brings the half anther at the end of the longer arm down upon its back where the pollen becomes deposited. The flower is protandrous and in a later stage the style elongates and is brought into the same position as occupied by the back of the bee when in contact with the anther.

Papilionaceous Types.—The Leguminosae show a very interesting series of pollination mechanisms. In this familiar type of flower, to which the pea and gorse belong, the essential parts of the flower are enclosed in the keel. The nectar is secreted by the inner sides of the lower part of the staminal tube; one of the ten stamens is usually free and at its base are two openings leading to the nectar. The nectar is thus not only carefully concealed but is also at a considerable depth. These flowers are bee flowers. An insect visiting the flower alights on the wings, thus depressing them and, as they are joined to the keel, this is depressed also. The stigma and stamens are thus forced out, the stigma usually first so that it has the chance of brushing off pollen from the underside of the bee and thus being cross-pollinated.

There are four different types. (1) Flowers in which the stamens and stigma return within the keel so that repeated visits are possible; examples are the clovers, melilot and laburnum. (2) Flowers that are explosive, since the style and stamens are confined under tension in the keel and when it is depressed they are released with suddenness, thus scattering pollen on the undersurface of the bee. Only one insect visit is thus effective. Examples are broom (*Genista*), gorse (*Ulex*), and lucerne (*Medicago*). (3) Flowers that display a piston mechanism—the pollen is shed early and the heads of the five outer stamens act as pistons so that the weight of the bee on the keel squeezes a narrow ribbon of pollen through the pore at the apex of the keel. A further pressure causes a protrusion of the stigma, which is thus brought in contact with the bee. Examples are lupin (*Lupinus*), restharrow (*Ononis*) and bird's-foot trefoil (*Lotus corniculatus*). (4) Flowers with a brush

mechanism, in which the pollen is again shed early and the style, which is provided with a brush of hairs, sweeps the pollen in small portions out of the tip of the keel. An example is the bean (*Vicia faba*).

Orchids.—The orchids show many and complicated adaptations to pollination by insects. A great impetus to their study was given by the publication in 1862 of Charles Darwin's monograph on the various pollination mechanisms exhibited by this group. As is well known, in this flower there is generally only one stamen, which is two-lobed, and the pollen is in the form of two-stalked masses, the pollinia, which the insect carries away stuck to its head. As the insect flies away, the pollinia, if not already properly oriented, execute such a movement as brings them into position to touch the sticky stigma of the next flower that is visited. There are, however, a great many variations in the details of this process. Nectar is not usually secreted by the orchid flower, but to obtain a sweet juice the insect has to pierce a special tissue, usually that of the labellum (the posterior petal), which is often spurlike. (See also ORCHID.)

Honeysuckle.—The honeysuckle (*Lonicera periclymenum*) is a moth flower. It is pale in colour and becomes highly scented in the evening. Probably the scent is here the distant guide and the pale colour, showing up in half light, acts at close quarters. The tube is so long that it can be plumbed only by moths, which suck in flight. Stamens and style project from the mouth of the corolla. On the first evening of opening, the style is folded down on the lower lip and only the stamens are touched. On the second evening the stamens are withered and empty and the style stands out, exposing the stigma.

BIRD POLLINATION (ORNITHOPHILY)

Pollination by insects is the basic type in flowering plants, but there has gradually accumulated a great deal of evidence that pollination by birds is widespread throughout the tropics and in some warm temperate regions, such as western Australia and parts of South America. In Brazil one-third of the plant families investigated were found to include ornithophilous species. The birds concerned are mostly hummingbirds and honey birds, creatures that may be no larger than a bumblebee. They suck nectar through a closed bill with the tongue acting as a piston. They usually suck in flight and are rough visitors, not so exact or so thorough as the bees. They require large quantities of liquid. They have little sense of smell. Their colour sense differs from that of the bee in that they distinguish reds, yellows and greens, but not blues. Corresponding to these characteristics of the bird are distinctive adaptations in the flowers frequented.

The most notable is the frequency of brilliant reds. Of 160 South American species known to be bird pollinated, 134 or 84% are red. Garish colour contrasts are frequent. The bird-of-paradise flower (*Strelitzia reginae*) is blue and yellow, appearing to the eye of the bird as a pattern of black and yellow. The flowers of *Billbergia* are pink and green. The stamens and styles stand clear of the corolla and resist rough treatment by their stiffness. The flowers have no landing platform, spurs or such features. When birds perch they usually do so on bracts or other strong structures near the flower. In the Chilean *Puya* the tip of the inflorescence forms a rigid, flowerless perch. The flowers have no scent, but nectar is very abundant, even welling from the mouth of the corolla.

These features may be seen in some plants commonly grown in European greenhouses and gardens. *Strelitzia* is prized as a greenhouse plant for its brilliant colour display. The garden fuchsia (*Fuchsia magellanica*) has flowers of crimson and blue. Style and stamens are stiff and project far out of the corolla. The nectar is so abundant that it can be shaken from the flower in drops. Even more interesting is *Salvia splendens*, the scarlet sage, extensively used as a bedding plant. It may be contrasted with the culinary sage described above. Apart from the colour it can be seen that the hooded petal and the broad landing stage are absent and that stamens and style are no longer enclosed but protrude from the corolla. It is a fine example of the way a flower fitted for bird pollination has evolved from the insect-pollinated type.

There can be no doubt that ornithophily is a later development than entomophily and that the bird flower has evolved from insect-pollinated ancestors.

POLLINATION BY OTHER ANIMALS

A remarkable arrangement exists between the yucca moths (*Tegeticula*) and yucca plants or Spanish bayonets, members of the lily family, found in the southwestern U.S. through Mexico and into Central America. Different species of the moth are adapted for pollinating different species of yucca. The female moth collects pollen from several stamens, then drills a hole through the wall of a yucca ovary and deposits her eggs among the undeveloped seeds. She then carries the collected pollen to the top of the pistil and forces it down the long, hollow style to the stigmatic surface where the pollen grains can germinate and thus fertilize the ovules. The relationship between plant and moth is mutualistic and absolutely obligatory, the plant being wholly dependent on the moth for pollination and the moth being wholly dependent on the yucca for feeding its larvae (some but not all of the developing seeds of the yucca being eaten by the larvae).

Among the bats some species of leaf-nosed bats in the new world and a group of flying "foxes" in the old world have evolved suctorial tongues and feed on nectar. They act as pollinators. The bat is night flying, clings to the flowers with its claws and is a rough visitor. Bat-pollinated flowers tend to stand away from the stems or to hang in free bunches; they are a dirty white in colour and have a peculiar smell. Details of visits by quick-flying nocturnal animals are naturally difficult to obtain. The extent to which bats effect pollination can be gauged by the fact that, in Java alone, 31 species of plants have been identified as bat pollinated.

In Australia about a dozen species of small marsupials—the honey mice—are nectar feeders and pollinate the flowers of species of *Eucalyptus*, *Protea* and other trees.

Various other animals, including snails, have been observed transferring pollen.

POLLINATION BY WIND (ANEMOPHILY)

The conifers, more primitive than the flowering plants, are all wind pollinated. The pollen is not transferred to a stigma, for these are naked-seeded plants. The ovule is exposed and the pollen is caught in a drop of liquid exuded from the micropylar opening of the integument. There is an enormous wastage of pollen drifting in air currents, and very great quantities are produced. A male yew shaken in February fills the air with "yew smoke." Lakes in the vicinity of pine woods may have their surface covered with a yellow film of pollen. The pollen is very light and powdery, in contrast to the sticky pollen of insect flowers. In the conifers male and female organs are always in separate cones and sometimes on separate trees.

There are many wind-pollinated flowering plants. They, too, produce light, powdery pollen in large quantities—as any sufferer from hay fever knows. The corolla is either little developed and green, or absent. There is neither scent nor nectar. Attractive characters are wanting. The lack of corolla is a positive advantage as it allows the free exposure of stamens and stigmas. The flowers stand well above surrounding foliage in the grasses, and appear before the leaves in such trees as the hazel and elm. The stigmas are often large and feathery, or covered with hairs acting as pollen traps. The individual stamen in the plantain and grasses, and the whole inflorescence in the hazel, is easily shaken, so that the pollen is readily dispersed when the air is in motion. Protogyny occurs, as in the plantain, and protandry, as in the grasses. Stamens and carpels occur in separate catkins in hazel, oak and beech.

The salad burnet (*Poterium sanguisorba*) in the Rosaceae and the meadow rue (*Thalictrum*) in the Ranunculaceae are examples of wind-pollinated flowers in families normally insect-pollinated. There is no doubt that these and others like them do not show a primitive condition but were evolved from insect-pollinated ancestors. The great group of wind-pollinated plants, which includes the grasses, sedges and rushes, may also exhibit a derived

HERMANN EISENBEISS

PINE TREES ARE WIND POLLINATED. IN THIS PHOTOGRAPH, TWO MALE CONES ARE SHAKEN TO ILLUSTRATE THE FINENESS OF THE POLLEN

condition. There is evidence to suggest that the most specialized family, the grasses, evolved through sedgelike and rushlike ancestors from showy-flowered plants of the lily type. The other great group of wind-pollinated plants, which comprises many forest trees such as the oak, birch, hazel and alder, offers a more difficult problem. It is possible that they are primitive types that have retained a primitive pollinating mechanism.

Pollination by the agency of water currents is very rare: an example is the grass wrack (*Zostera marina*).

SELF-POLLINATION (AUTOGAMY)

Self-pollination frequently takes place at the end of the life of a flower, ensuring fertilization if cross-pollination failed. It is often brought about by movements of the stamens or style. It is well seen in the Compositae where the branches of the style curl back and bring the stigmas into contact with their own pollen. There is great variety of detail in other flowers.

Some flowers never open and are said to be cleistogamous. They are small and budlike and petals are reduced or absent. The wood sorrel (*Oxalis acetosella*) and the sweet violet (*Viola odorata*) are examples.

APPLICATIONS

The fig is pollinated by a small wasp that passes from male to female flowers. The two are borne on separate trees and the male fig, which bears no fruit, is called a goat fig or caprifig. It was known in Greece in the time of Aristotle that goat figs must be planted near the fruiting trees, or branches placed in their crowns: the practice is known as caprifigation and still goes on. When the Smyrna fig was introduced into California at the end of the 19th century the goat fig and its wasps had to be brought in as well.

TWO TYPES OF FLOWER OF THE CHINESE PRIMROSE ILLUSTRATING A STRUCTURAL BARRIER TO SELF-POLLINATION: (A) PINHEAD TYPE; (B) THURMHEAD TYPE

The date is another Mediterranean fruit tree that has been artificially pollinated from time immemorial by hanging male inflorescences among the female. The peach, when grown in the greenhouse, is usually pollinated by hand, using a brush or hare's foot; so is the melon. In the orchard it is often an advantage to make sure of adequate pollination by having beehives among the trees.

Red clover, which can be pollinated only by bumblebees with their heavy bodies and very long tongues, was a failure when first introduced into New Zealand but succeeded when the bee was successfully established.

Artificial pollination is essential in all breeding work. When crosses are made it is usual to remove the stamens before they are ripe and to enclose the flower or inflorescence in a paper bag to avoid chance pollination. The most suitable technique must be worked out for each plant and an intimate knowledge of the development of the flower is required. When growing crops for seed production it is necessary to make sure that crossing with other varieties, and consequent impurity in the seed stock, does not occur. The cereals give little trouble in this respect, for they are almost entirely self-pollinated. With other crops—such as cabbages and beets—this is not so. Plots must be isolated by distance, by hedges or otherwise. Exact knowledge of pollination agencies is the basis of such precautions.

See P. Knuth, *Handbook of Flower Pollination*, trans. by J. R. Ainsworth Davis, 3 vol. (1906-09), which includes an account of the work of such pioneers as C. K. Sprengel, C. Darwin and H. Müller; B. J. D. Meeuse, *The Story of Pollination* (1961). (V. H. B.; M. Se.)

POLLIO, GAIUS ASINIUS (76 B.C.—A.D. 4 or 5), Roman orator, poet and historian whose contemporary history, although lost, provided much of the material for Appian and Plutarch. Born into a leading Marrucine family—his grandfather had been an Italian general in the Social War—Pollio moved in the literary circle of Catullus and entered public life in 56 by supporting the policy of Lentulus Spinther (*q.v.*). In 54 he impeached unsuccessfully the tribune C. Cato, incurring Pompey's displeasure. In the Civil War he joined Caesar at the Rubicon and campaigned in Africa with Curio and (49-45) in Greece, Africa and Spain with Caesar, for whom he held a praetorian command in Spain against Sextus Pompey (44). On Caesar's death he followed Antony, for whom he governed Transpadane Gaul. There he was friendly with Virgil and in distributing land to veterans saved the poet's property from confiscation. He stood aloof from Fulvia, Antony's wife, and L. Antonius in the Perusine War, but held his army firmly in Antony's interests, and shared in the negotiations leading to the pact of Brundisium between Antony and Octavian in 40. In that year he was consul, and Virgil addressed his Fourth Eclogue to him. In 39 Pollio subdued the Parthini, an Illyrian people, and celebrated a triumph (Oct. 25). From the booty he built the first public library in Rome, in the Atrium Libertatis, which he restored. With full honours he then retired from public life. Unwilling to join Antony in the east, hoping for nothing from Octavian, he took no part in the Actium campaign (31) and subsequently maintained a position of republican dignity and independence. He gave hospitality to the rhetorician Timagenes, when the latter was in disgrace with Augustus. This was the main period of his activity as an advocate, and he devoted himself to the support of literature, organizing public recitations. He died in his villa at Tusculum.

Pollio was a distinguished orator, combining, according to Tacitus and Seneca, careful composition and dry Atticist elegance in strict presentation of his argument. His style displeased Ciceronian critics such as Quintilian and his speeches are lost. As a poet he was accepted by Catullus, Helvius Cinna and Virgil and wrote tragedies, which Virgil and Horace praised, but he ceased to write serious verse when he turned to history shortly after 35. His *Historiae* covered the period from 60 probably to 42 (hardly as late as 35 or 31), that is, from the First Triumvirate to Philippi—the period in which the Roman republic fell. To this contemporary work ("a work full of perilous hazard"), Pollio brought personal experience, independent judgment and a sober style that

aided historical analysis. Pollio may be ranked with Sallust and Tacitus. A stern critic of men and style, he corrected Caesar, attacked Cicero, praised Brutus, and reprimanded Sallust for archaism and Livy for *Patavinitas* (probably "provincialism"). Above all, he defended Roman *libertas* under the *principatus* of Augustus. His three letters to Cicero (*Ad Cam.* x, 31-33) bring him closer to the reader than any other work.

Peters, vol. ii, pp. 67-70, pp. lxxxiii-lxxxvii (1906). See also R. Syme, *The Roman Revolution*, p. 5, 91 (1939), and Tacitus, p. 136 (1958); E. D. Pierce, *A Roman Man of Letters* (1922); J. André, *La vie et l'oeuvre d'Asinius Pollion*, with bibliography (1949); E. Gabba, *Asinio* (1956). (A. H. McD.)

POLLOCK, the name of a great English legal family. The best-known members are:

SIR JONATHAN FREDERICK POLLOCK (1783-1870), chief baron of the exchequer, was born on Sept. 23, 1783, in London, the son of David Pollock, saddler, of Charing Cross. He was educated at St. Paul's and Trinity college, Cambridge, and was called to the bar in 1807. He took silk in 1827, and in 1831 became member of parliament for Huntingdon. In 1834 he became attorney general and was knighted. His party lost office in 1835, but he was again attorney general from 1841 until in 1844 he succeeded Lord Abinger as chief baron of the exchequer. In 1866 he retired with a baronetcy, and on Aug. 22, 1870, he died at Hatton, Middlesex.

SIR FREDERICK POLLOCK (1845-1937), 3rd Bart., a grandson of the chief baron, and a notable author, was born in London on Dec. 10, 1845. He was educated at Eton and Trinity college, Cambridge, where he became a fellow in 1868. He was called to the bar by Lincoln's Inn in 1871 and for several years he practised, though with little success. After holding various teaching posts, from 1883 to 1903 he was Corpus professor of jurisprudence at Oxford. In 1885 he played a leading part in founding the *Law Quarterly Review*, the distinguished learned legal periodical of the common-law world, which he edited for the first 34 years. He also edited the *Law Reports* from 1895 to 1935. In 1911 he was made a privy councilor and in 1914 judge of the admiralty court of the Cinque Ports, an office with only nominal duties. In 1920 he became one of the first of the few academic lawyers to be made a king's counsel. He died in London on Jan. 18, 1937.

Sir Frederick Pollock's *Principles of Contract* was in many ways the first of the modern textbooks with a critical, analytical and learned approach, concentrating on principles rather than details. For over half a century his writings, especially in the *Law Quarterly Review*, exerted an influence on the development of English law that was unprecedented for an academic lawyer. Yet Pollock was no mere lawyer; he was a true scholar who was widely read in many tongues, both in law and other subjects, especially philosophy. Although somewhat reserved in his manner, he could be an effective speaker; and he was kindness itself to the serious student. Much of his remarkable personal and intellectual friendship of over 60 years with Justice Oliver Wendell Holmes, Jr., is revealed by their correspondence, published in 1941 and edited by M. de W. Howe.

Sir Frederick Pollock's works include *Principles of Contract* (1876; 13th ed., 1950); *Digest of the Law of Partnership* (1877; 15th ed., 1952); *The Law of Torts* (1887; 15th ed., 1951); *Possession in the Common Law*, with R. S. Wright (1888); *The History of English Law Before the Time of Edward I*, 2 vol., with F. W. Maitland (1895; 2nd ed., 1898); *Spinoza, His Life and Philosophy* (1880; 2nd ed. reissued with additions, 1912).

POLLOCK, JACKSON (1912-1956), U.S. abstract painter, one of the founders of a loose movement called Abstract Expressionism or Action painting in the U.S. and *tachisme* in France, was born at Cody, Wyo., on Jan. 28, 1912. After a period of realism after the style of Thomas Hart Benton, Pollock's first

paintings in the new style, in 1943, mingled energetic linear invention and a subconscious imagery derived from Surrealism. His later work was entirely abstract, characterized by an intense activism of surface and by the interweaving of whipped lines. After 1947, Pollock employed aluminum paint and commercial enamels, dripping and spattering them over the canvas surface. This radical technical innovation brought him unfavourable publicity, but also helped identify him in the minds of many young American artists as the most revolutionary artist of an older generation of innovators. Pollock died at East Hampton, L.I., N.Y., on Aug. 11, 1956. Abstract Expressionism became one of the dominating international tendencies after the close of World War II. Its aesthetic principle is based upon free and expressive handling and unarranged, chance pictorial effects, which seem to arise spontaneously under the brush stroke. (S. H.V.)

POLLS, PUBLIC OPINION: see PUBLIC OPINION.

POLL TAX, a tax of a uniform amount levied on each individual or "head" (middle English *polle*, "a head"). This tax has long been abandoned by most countries and is not an important source of revenue in any tax system in the world.

The most famous poll tax in English history is the one levied in 1380, which led to the revolt of the peasants under Wat Tyler in 1381, but the first instance was in 1377, when a tax of a groat a head was voted by both clergy and laity. In 1379 the tax was again levied, but on a graduated scale. John of Gaunt, duke of Lancaster, paid ten marks, and the scale descended from him to the peasants, who paid one groat each, every person over 16 years of age being liable. In 1380 the tax was also graduated, but less steeply. For years after the rising of 1381 money was raised in this way only from aliens, but in 1513 a general poll tax was imposed. This produced only about £50,000 instead of £160,000 as was expected, but a poll tax levied in 1641 resulted in a revenue of about £400,600. During the reign of Charles II, money was obtained in this way on several occasions. For years after 1688 poll taxes were a favourite means of raising money for the prosecution of the war with France.

Although a few U.S. states at mid-20th century still levied the tax for revenue purposes, most discussion of the tax centred around its use as a voting prerequisite in the Southern states. Ten Southern states made payment of the poll tax a voting prerequisite between 1889 and 1902; an 11th, Georgia, had enacted the requirement many years earlier. In its origins the tax is associated with the agrarian unrest of the 1880s and 1890s, which culminated in the rise of the Populist Party in the West and the South. The Populists, a low-income farmers' party, gave the Democrats in these areas the only serious competition they had experienced since the end of Reconstruction. The intensity of competition led both parties to bring the Negro back into politics and to compete for his vote. Once the Populists were defeated the Democrats amended their state constitutions or drafted new ones to include various disfranchising devices. The poll tax was one of these. Its purpose was to disfranchise Negroes and possibly also to weaken politically the poor whites who had made up the backbone of the Populist Party.

Beginning in 1920 the poll tax was abolished by state action in North Carolina, Louisiana, Florida, Georgia, South Carolina, and Tennessee. In 1937 the Supreme Court unanimously upheld the constitutionality of a Georgia poll tax. Constitutional amendments to abolish the tax were submitted to the voters in Arkansas, Virginia, and Texas, but failed to pass. The tax still prevailed in these states as well as in Alabama and Mississippi at mid-century; the rate ranged from \$1 to \$2 per year. In Texas and Arkansas, failure to pay merely disfranchised a person for that year only and did not create an obligation that had to be paid in subsequent years if he wished to vote. In Alabama, Virginia, and Mississippi the tax was in some degree cumulative. As a requirement for voting for federal offices, however, the poll tax was prohibited in 1964 by the 24th Amendment to the U.S. Constitution. A poll tax that was not a requirement for voting, as in New Hampshire, was not affected by the amendment. In 1966 the Supreme Court went beyond the 24th Amendment by ruling that under the "equal protection" clause of the 14th Amendment states could not

levy a poll tax as a prerequisite for voting in state and local elections, thus outlawing such poll taxes in Virginia and apparently also in Texas, Mississippi, and Alabama.

See F. D. Ogden, *The Poll Tax in the South* (1958). (D. S. Se.; X.)

POLLUCITE, a rare mineral consisting of hydrated cesium aluminum silicate, is the richest source of cesium, the oxide being present to the extent of 30% to 36%. Cesium, together with rubidium, is important in the manufacture of photoelectric cells, scintillation counters, and optical instruments and devices. Pollucite occurs sparingly, associated with the mineral petalite (*q.v.*) in cavities in the granite of Elba, and with beryl in pegmatite dikes at Andover and Hebron, Me., and in the pegmatite mines of the Black Hills, S.D. It also is found in Brazil, South West Africa and South Africa.

The composition of pollucite is $\text{CsAlSi}_2\text{O}_6 \cdot \text{H}_2\text{O}$. It is closely related to leucite, KAlSi_2O_6 . It crystallizes in the cubic system, is colourless and transparent and has a vitreous lustre. There is no distinct cleavage and the fracture is conchoidal, so that the mineral closely resembles quartz. The hardness is 6.5 and the specific gravity 2.90.

See also CESIUM.

(L. S. RL.; X.)

POLLUTION, ENVIRONMENTAL. The environment includes the complex of physical, chemical, and biological factors surrounding an organism or an ecological community. Such factors act and interact with various species of organisms to affect their form, growth, and survival. Since an environmental element that is a pollutant with respect to certain species may be a desirable nutrient to other species, the definition of pollution and contamination often becomes difficult. The terms are especially difficult to define in relation to so complex an organism as man. The simple fact that man or any other organism lives gives rise to environmental pollution by the release and buildup of metabolic excretion products unless such materials are utilized by other organisms to balance the ecology. Moreover, in converting energy and matter into marketable products, man is frequently inefficient, wasteful, and inconsiderate, thus giving rise to contaminants of industrial origin. The modern problems of environmental pollution, then, are essentially those of rapid human population growth and expanding technology.

Elements of Pollution.—Environmental contaminants include products of combustion; human excreta; expired air; dusts; pathogenic organisms; vapours; gases; industrial solvents; extremes of temperature; agricultural fertilizers; infrared, ultraviolet, and even visible light; ionizing radiations; radioisotopes; noise; ultrahigh-frequency sound; and certain microwave electromagnetic radiations. Presence of such biological, chemical, or physical agents per se, however, does not necessarily make them pollutants. Quantitative evaluation as to time, place, amount, and detrimental effect is required for an adequate definition of pollution.

Contaminants present in strong enough concentration to pose an immediate threat to life or to cause frank cases of disease or acute poisoning are usually readily apparent, and experience has led to the development of adequate, but by no means perfect, environmental control measures. Although accidents attributable to such pollutants still occur with disturbing frequency, preventing them is largely a matter of education and regulation. With new products of science and industry, though they are frequently tested for toxicity and hazard, untoward effects from pollution may not be immediately apparent. But over a span of time, medical statistics frequently reveal that persons experiencing similar illnesses have been exposed to a common environmental factor. Where such exposures to contaminants occur in the work environment, especially in industries adequately staffed with occupational health personnel, investigation usually leads to resolution of the problem and application of control measures. More time is usually required to diagnose and prevent illnesses due to exposures of the same magnitude in home, avocational, or recreational environments.

The effects of environmental contaminants on organisms, or for that matter on inanimate materials, are related to time as well as concentration or intensity. Thus such factors as duration of ex-

posure, frequency of repetition, and recovery period are significant. Time factors become increasingly important and also more difficult to measure and account for when low concentrations of contaminants do not produce ill effects until after months or years of exposure. If the concentration is so low that no harmful effect is measured after a full lifetime of exposure, the level may be considered negligible, at least in regard to life processes. But with some contaminants that are odorous, corrosive, or otherwise objectionable at concentrations lower than those producing measurable health problems, the nuisance, economic, and aesthetic values are of considerable moment; in the general outdoor environment they presently outweigh directly measurable health effects. In confined work space, however, permissible contaminant criteria are usually based upon human health considerations.

Problems of Control.—The question naturally arises, "Why permit any of these pollutants to contaminate our work and living spaces?" For such a simple question, the answer is complex. First of all, there is no such thing as absolute zero as far as the existence of matter and energy is concerned. It can only be approached. For example, specification of a zero tolerance of pesticide residues on foodstuffs really means that no measurable amount of the pesticide may be present, not that absolutely none is present. Of course methods of detection and measurement should be sensitive enough to indicate the presence of harmful concentrations. On the other hand, as better analytical techniques are devised, it would be absurd to reject foodstuffs for human use because of trace quantities of harmless pollutants. Next, various types of matter and energy are harmful or beneficial depending largely upon concentration, time of exposure, physical state, and opportunity for contact. For example, the lead in ordinary fishing sinkers is toxic when vaporized, recondensed as very fine particles, and inhaled by man for appreciable periods at concentrations much in excess of 0.2 mg. per cubic metre of air. The otherwise harmless sugars in waste waters from wood-pulping processes can through bacterial action readily deplete the oxygen in receiving bodies of water, thus destroying fish life and even converting some streams into open septic tanks. Sunlight, which is essential to living things, contains cancer-producing radiations and is probably the most frequent cause of skin cancer. Thus contaminants or pollutants are usually useful substances or energy forms that have many beneficial applications; it is only when they are used carelessly and without knowledge, or wastefully so as to produce excessive concentrations in the environment, that pollution really occurs.

Elimination of waste is the crux of environmental pollution control. Unfortunately, the economy of highly industrialized nations is predicated upon a philosophy of waste in connection with many products. This is especially true where raw materials are abundant. Thus with plastic products manufactured from polyethylene, polypropylene, or other nonbiodegradable polymers, there is a solid-waste-disposal problem. On the other hand, matter and energy left over from industrial processes, commercial manufacture, or conversion of fuels to motive power, electricity, light, or heat are considered to be wastes only because they have little recovery value. Such waste products create problems in the home, work place, outdoors, in rivers, lakes, oceans, the atmosphere, and even nearby outer space.

Control of environmental pollution requires efficient manufacturing and energy-conversion processes; conscientious efforts to eliminate waste at the source; the measurement of effects on human health as well as on plants, animals, and structures; determinations of efficacy of natural processes to cope with waste discharges of a particular magnitude within certain ecological boundaries; economic evaluations; political and legislative actions; and the education of policy makers to obtain realistic support of abatement measures. These generalities apply to air pollution, water pollution, air and water resource management, industrial hygiene, food sanitation, nuclear waste disposal, and radiological health protection. Although various types of pollution are related by the basic and derivative sciences of chemistry, physics, biology, and mathematics, they will be considered in this article by the place, or medium, in which contamination takes place.

WATER POLLUTION

Water Resources.—Water is our most abundant resource. Worldwide there are about 1.4×10^{21} litres of water. If it could be evenly allocated, this would provide approximately 420,000,000,000 litres (110,880,000,000 U.S. gal.) per person. Most of this water is contained in the oceans and, as far as most human use is concerned, is contaminated with a wide variety of dissolved salts in relatively high concentrations. Use and reuse of this vast store of water for freshwater purposes depends mainly upon natural desalinization. Though several industrial processes exist for desalinization of sea or brackish water, they are not competitive economically with natural water-supply developments or reclamation of soiled fresh water, such as domestic sewage, except in unusual geographic locations.

So-called shortages of water are not caused by a short supply of water itself but rather by excessive demands being made upon water resources and by lack of adequate storage, treatment, and distribution facilities. The amount of water in existence is increasing at the rate of 950×10^8 litres each year due to the combustion of petroleum fuels alone. Resynthesis of this water to form fossil fuels is essentially nil, although photosynthetic generation of new plant matter and free oxygen may be appreciable. As far as technological capabilities are concerned, water of any desired quality may be supplied to almost any place at any time in adequate quantities—for a price. Though water is the most used and usually the cheapest commodity required by man, the problems of obtaining sufficient lead time and allocation of funds for developing water supplies and protecting water resources from pollution are frequently of major importance. Water and wastewater projects, because of their magnitude and social nature, are frequently supported by municipal, state or provincial, or national governments. The extent of such support reflects public understanding and political foresight based upon sound engineering projections.

Water Supply and Waste-Water Disposal.—Of the various areas of environmental health engineering, water supply and wastewater disposal are the most sophisticated and most widely developed (see WATER SUPPLY AND PURIFICATION; SEWAGE DISPOSAL). Historically the design, construction, and management of public water supplies and waste-water disposal systems were allied to the growth of capital cities and religious or trade centres. Remnants of large and complex installations stand as monuments to early engineering. Notable among the ancient structures are the aqueducts and sewers of Rome. Sextus Julius Frontinus, water commissioner of Rome (A.D. 97), reported the existence of nine aqueducts supplying water to Rome, varying in length from 16 to more than 80 km. (10 to 50 mi.) and in cross section from 0.65 to more than 4.6 sq.m. (7 to 50 sq.ft.). The aggregate capacity of the Roman aqueducts has been estimated at 320,000,000 litres (84,500,000 U.S. gal.) per day. The ancient peoples were well aware of the relationships between pure water, excreta disposal, and good health, though not in terms of modern microbiology, chemistry, and physics, and they adopted civic and religious laws pertaining to water uses and excreta disposal.

Since the mid-19th century the effectiveness of environmental health engineers in providing potable water to well-developed areas has been so great that most people in North America and Europe are no longer aware of waterborne agents of disease. Although engineers are faced with the problem of refining lake, river, and ground waters containing more and more contaminants, the emphasis in water supply has shifted from health considerations to considerations of quantity and economics. The various aspects of water quality and quantity, however, are interrelated, and as large uncontaminated stores of water become increasingly hard to preserve, due to human population growth and industrial burdens, better and more reliable water purification processes will be needed. There will also be a need for purifying waste waters and raw waters, since natural processes can no longer accomplish most or all of this.

Despite the widespread delivery of potable water and consequent decline in emphasis on health considerations, neglect to apply available knowledge can give rise to an untoward incidence of

disease, as was attested by an epidemic of gastroenteritis that occurred in the spring of 1965 in Riverside, Calif. During a one-month period more than 1,500 cases of gastroenteritis, including 3 deaths, were reported to health officials before the widespread, sporadic nature of the epidemic led to the suspicion that the disease was waterborne. It was later estimated that as many as 10,000 to 15,000 persons may have been affected. The epidemic reached its peak on May 22, but it was not until seven days later that the cause was finally traced to the water supply, which was found to contain the bacterium *Salmonella typhimurium*. The community water supply, from deep wells inside and outside the city, had never been chlorinated. Even though water at the source of supply may meet sanitation standards, the opportunities for subsequent contamination in the distribution system of a city the size of Riverside (pop. [1965 est.] 133,000) are so frequent during routine maintenance and operation that a disinfection method must be used that provides residual power throughout the entire network.

Pollutants.—Although water pollutants can be classified generally as physical, chemical, or biological, several categories are of particular concern.

Excreta and Organic Industrial Wastes.—Human excreta are discharged to water carriage systems of waste collection for subsequent discharge to receiving streams or other bodies of water. Organic constituents in these excreta products serve as food for indigenous microorganisms that carry out oxidative processes. If the organic constituents are excessive after the treated or untreated waste water is diluted by discharge into the receiving body of water, the biochemical oxygen demand of the stabilizing organisms may deplete the available oxygen in the water, thereby upsetting normal ecological conditions and producing pollution. Ordinary organic constituents from food processing plants, paper manufacturing, malting and distilling processes, and various other industries also contribute to the biochemical oxygen demands made upon natural waters.

Infectious Agents.—Sewers receive almost every type of pathogenic organism known to man and probably some that have yet to be identified. Fortunately the aquatic environment in sewers and in waste treatment plants is hostile to most pathogens, and extinction occurs within a reasonable period of time. Surviving species of pathogenic bacteria have been successfully prevented from contaminating potable waters by various treatment and disinfection processes. As far as bacterial waterborne diseases are concerned, testing for a few species of microorganisms of enteric origin as indicators of fecal contamination provides excellent control. These coliform organisms, hardier and more numerous than associated enteric pathogens, can be detected and estimated numerically by relatively simple bacteriological procedures. If a population density of less than ten coliform organisms per litre of water is found, the possibility that bacterial pathogens are present is negligible. A so-called negative coliform test, however, does not preclude contamination with viruses. Good, easily applied control tests for virological contaminants are needed, and maximum permissible concentrations of various trace substances need to be established based upon toxicologic, economic, and aesthetic factors.

Plant Nutrients.—In well-developed nations such as the United States, Great Britain, France, and Germany, more than 75% of the people reside in cities. A constant flow of foodstuffs produced largely through photosynthesis of soil minerals is required to feed them. Unfortunately the nitrogen, phosphorus, and other elements essential to life are not returned to the land for completion of the ecological cycle but instead are discharged to watercourses in waste waters or disposed of locally as garbage. To replenish minerals in agricultural areas, vast amounts of fertilizers, not commonly thought of as pollutants, must be used. If significant quantities of fertilizers are carried by rainwater runoff or groundwater seepage into lakes or streams, however, lush growths of algae may occur. In normal amounts such algae contribute to the oxygen balance in lakes and streams, and they also serve as food for fish. But with excessive amounts of nitrogen and phosphorus, several species of algae are capable of growing so rapidly in a fa-

vourable aquatic environment that they crowd out other populations of organisms, overgrow, and finally die because of exhaustion of available nutrients and autointoxication. Various species of bacteria then begin to decay and putrefy the dead algal bodies, which in turn depletes the oxygen resources of the lake or stream and gives rise to offensive odours.

Organic Pesticides.—Toxic chemicals have long been employed to control or eliminate insects, vermin, and weed plants that destroy crops, harm domestic animals, or spread disease (see *SPRAYS AND DUSTS IN AGRICULTURE*). Since 1930 the armamentarium of pesticides, insecticides, and herbicides has grown by leaps and bounds. They have had a tremendous influence upon agricultural productivity and have now become essential to nearly every food-producing activity. The toxic character of pesticides has resulted in the development of a wealth of toxicological data. Governmental regulations in a number of countries require rigorous testing of newly developed pesticides before they are released for use. The widespread use of pesticides and the universal nature of water made it inevitable that pesticides would appear as stream pollutants and even as contaminants in drinking water. Although the incidence of human poisoning from regulated sources of public water supply has been essentially nil since mid-20th century, occasional instances have occurred as a result of cross connections of industrial-process piping or tanks with potable water distribution lines. Moreover, stream pollution from pesticides has occurred, and concern about the long-range effects of low concentrations of these toxic chemicals is justifiable, especially since new and more effective pesticides are being developed rapidly. Chemical and physical methods for detecting and measuring such substances in water are available, and standards of permissible concentrations in streams, lakes, and drinking water should be established.

Waste Minerals and Chemicals.—Untreated industrial wastes discharged into lakes and streams can result in serious problems of water pollution. Dissolved minerals, especially calcium and magnesium salts, cause hard-water problems for industrial and municipal water supplies. Toxic chemicals may alter the normal biological activity of streams, and many chemicals react with water to raise the acidity or alkalinity of streams to a point where the water becomes corrosive and living organisms are killed. Chemicals with a high oxygen demand add to the problems of deoxygenation. Although for drinking water upper limits have been developed on the concentrations of several chemicals such as arsenic, barium, chromium, cyanide, lead, and phenols, no general rules exist for the treatment of industrial wastes because of the wide variety of organic and inorganic waste materials involved.

Sediments.—Sediments from waste waters contribute to the turbidity of lakes and streams, affecting their surface-water quality. Sediments also form banks of sludge that can eventually dam or fill up narrow or shallow channels. Anaerobic decomposition of the sludge materials draws heavily on the oxygen content of the water and results in the release of noxious gases.

Radioactive Substances.—While a number of radioisotopes, the radioactive forms of chemical elements, occur naturally, their relative abundance in nature is usually small. With the discovery of nuclear reactions and the development of methods by which they can be controlled and utilized on a large scale, radioisotopes are being produced in large quantities, not only in natural forms that had previously been identified, but also as new mutants of the various chemical species (see *ISOTOPE*). Many of the man-made radioisotopes are quite valuable and are useful in industry, agriculture, and medical diagnosis and treatment. In the production of energy from nuclear reactions, however, quantities of fission products are produced far in excess of current demands for such radioactive elements. Thus a potentially serious problem attends the disposal of radioactive wastes. Materials that emit ionizing radiations are capable of producing cancer, disrupting basic biological processes, and causing genetic changes in various types of organisms, including man. As with practically all other wastes, the disposal of nuclear wastes, whether gaseous, liquid, or solid, has classically followed two divergent paths: "CC," which stands for concentrate and confine, or "DD," dilute and disperse. However,

both methods have their shortcomings. Dilution leads to contamination of more and more waters to the point where radioactive decay cannot keep up with the discharge of new radio contaminants. The alternate method, though relatively costly, is the method that must be used if widespread utilization of nuclear energy is to be achieved.

Heat.—As with all things out of place or out of balance, heat can be a water pollutant. Power plants for converting fossil fuels into electrical energy, petroleum refineries, chemical process plants, steel mills, coke ovens, and nuclear reactors all draw large quantities of water from watercourses and return it at elevated temperatures. Such temperature shifts in the aquatic environment upset the existing ecology, sometimes enough to drive out or kill desirable species of fish or to cause rapid oxygen depletion. Since the compound rate of increase of energy consumption for the world is currently about 3.5% per year (doubling time is 20 years), heat pollution is apt to develop into a major problem unless more efficient energy utilization is employed. This is especially pertinent for the United States, which doubles its consumption of energy resources in only 12 years.

Fluorides.—The concentration of fluorides in potable water deserves special mention because both upper and lower limits for it have been recommended. During the years of human tooth formation consumption of waters containing the proper amount of fluoride affords resistance to tooth decay, while waters containing too much fluoride are capable of producing dental fluorosis, a mottling of the tooth enamel. The recommended optimum control limits for fluoride in drinking water range from 0.7 to 1.2 mg. per litre, depending upon the annual average of maximum daily air temperatures of the community to which the water is supplied. Any potable water supply bearing less than 0.6 mg. of fluoride per litre should be considered deficient, while one containing more than 1.7 mg. per litre may produce an occasional case of mottled enamel.

AIR POLLUTION

Air pollution, like other forms of environmental pollution, is directly related to fuel usage, increased industrialization, and growing urban populations. This historical relationship is perhaps somewhat more direct and apparent for atmospheric than for water pollution. The first smoke abatement law was passed in England in 1273, during the reign of Edward I, in response to a popular belief that food cooked over burning coals would cause illness and even death. In 1306 the concern about air pollution was so great that a royal proclamation prohibited the burning of coal in London. The first recorded penalty imposed for violating an air pollution code occurred when a manufacturer who had disobeyed the proclamation was tried, found guilty, and beheaded.

In defining air pollutants it is common to consider only those substances added in sufficient concentration to produce a measurable effect on man, animals, vegetation, or inanimate materials. Pollutants may therefore include almost any natural or artificial composition of matter capable of being airborne. They may occur as gases, liquid droplets, or solid particles, or in various mixtures. It is convenient to consider two groups of air pollutants: (1) primary emissions from identifiable sources; and (2) products formed in the air by interaction between two or more primary contaminants or by reaction with normal atmospheric constituents, with or without photochemical activation.

Primary Contaminants.—Although it is possible to determine the kinds and amounts of primary contaminants emitted from each source in a community, their end products and effects cannot be predicted with certainty from these data alone. Such data define the primary reactants and, after reaction chains are identified, enable abatement of primary emissions. Primary emissions include: fine solids less than 100 μ in diameter; coarse particles greater than 100 μ in diameter; sulfur compounds; organic compounds; nitrogen compounds; oxygen compounds; halogen compounds; and radioactive compounds.

The fine aerosols include carbon particles, metallic dusts, silicates, fluorides, resins, tars, pollen, fungi, solid oxides, nitrates, sulfates, chlorides, aromatics, and a host of other chemical species

that overlap many of the more specific categories. As particles they scatter light according to established physical laws, and they afford opportunity for catalysis of otherwise slow interactions among adsorbed pollutants due to their finely divided state. As carriers of electrostatic charges they influence the condensation and coalescence of other particles and gases. As chemical species some of them are highly toxic to plants and animals or are corrosive to metals. To the extent that they are radioactive they increase the normal radiation dosage and may be cancer- or mutation-producing factors. Finally, as plain dust, they soil clothing, buildings, and bodies, and are a general nuisance.

Coarse particles 100 μ in diameter and larger present similar problems but in a greatly diminished degree because of their rather prompt removal from the air by gravitational attraction. Their size also prevents significant quantities from entering human or animal lungs. However, their soiling effect may be more evident than that of the fine particles because they are not widely dispersed but rather are deposited quickly around the source of discharge.

Interest in sulfur compounds has been intense for a long time because of the irritating effects of sulfur oxides and the high toxicity of hydrogen sulfide. Organic compounds released to the atmosphere include a large number of hydrocarbons, together with their combustion products and halogenated derivatives. These contaminants are mainly emitted as vapours, though some may occur as droplets or particles. Among these hydrocarbons, a number, notably the polynuclear aromatics, have been associated with carcinogenesis in mammalian test animals. The majority, though, have relatively low potential for serious air pollution effects so long as they retain their specific identities. Nitrogen compounds most abundantly generated and released to the atmosphere are nitrogen oxides and ammonia. Oxides of nitrogen are produced in high-temperature combustion and other industrial operations. Although nitrogen dioxide is irritating at fairly low concentrations, the major interest in nitrogen oxides as air contaminants is related to their participation in atmospheric photochemical reactions.

Large amounts of carbon dioxide and carbon monoxide arise from the complete and partial combustion of carbonaceous fuels. The production of carbon monoxide in Los Angeles County, Calif., has been estimated to exceed 10,000 tons (10,000,000 kg.) daily, at least 80% of it arising from incomplete utilization of the carbon in automobile gasolines. Carbon dioxide in high concentrations affects the human respiratory control mechanism, but the concentration required is too great to be of much significance. Although the doubling time for fuel consumption in the world is presently 20 years, statistically significant evidence of a buildup in atmospheric carbon dioxide concentrations has not been established, even though the burning of carbonaceous matter has produced great quantities of carbon dioxide. Measurements during the past century, however, indicate that worldwide they may be increasing. Concern has been expressed by some scientists about such an occurrence, since carbon dioxide is an excellent absorber of infrared radiant energy. Recent calculations indicate that a doubling of the carbon dioxide concentration in the atmosphere would cause an average rise in the earth's surface temperatures of about 3.6° C (6.5° F). A temperature shift of this magnitude would have far-reaching hydrological and meteorological effects; the polar ice masses would be reduced and the ocean levels would rise. Although the carbon dioxide theory has plausibly explained the climatic oscillations of geologic time, accompanied by the coming and going of glacial periods, the present annual production of carbon dioxide by fuel combustion is only enough to raise the global atmospheric concentration by 1 or 2 parts per million, approximately less than 0.0002% if not counterbalanced by plant photosynthesis. Since the carbon dioxide concentration of the atmosphere is about 300 parts per million (0.03%), the production over a few years would appear to be insignificant. Furthermore, the available sinks of marine and terrestrial plant life capable of reducing carbon dioxide seem entirely adequate to maintain the ecological balance for centuries unless other factors come into play. The problem of air pollution with carbon dioxide therefore does not seem to be alarmingly great. Quantitatively, however, knowledge is lacking. Carbon monoxide, unlike carbon dioxide, deserves

status as a primary pollutant due to its ability to impair the oxygen-carrying capacity of hemoglobin in blood.

Inorganic halogen compounds are produced from metallurgical and other industrial processes. Among these, hydrogen fluoride and hydrogen chloride are corrosive and irritating in themselves, and the metallic fluorides have toxic properties which have precipitated intricate and costly legal actions between operators of factories and nearby residents whose crops and cattle have been damaged. Radioactive contaminants have not presented any major practical problems beyond the vicinities of nuclear energy generation, development, and research installations. That they will do so with increased use of nuclear power and industrial and medical applications is certain.

Secondary Contaminants.—The contaminant-containing air mass over a populated area is both chemically and physically unstable, and the ensuing reactions give rise to secondary pollutants. The reaction rates, routes, and intermediate steps involved in generating new pollutants are influenced by many factors, such as concentrations of reactants, extent of photoactivation, meteorological forces, local topography temperatures, and relative amounts of moisture. Of important consequence is the formation of sulfates from sulfur dioxide and nitric oxide plus free oxygen radicals from nitrogen dioxide. The latter substances are able to initiate sustained free radical reaction chains. Secondary pollutants, which are among the most troublesome to control, include ozone, formaldehyde, organic hydroperoxides, and other very reactive compounds and free radicals.

Major Disasters.—Although serious incidents of air pollution are infrequent, four major disasters have been recorded. The first occurred in the Meuse Valley between Seraing and Huy, Belg., between Dec. 1 and 5, 1930, when a large number of persons became ill and more than 60 died. Elderly persons who had medical histories of heart or lung impairments accounted for most of the deaths. The symptoms, mainly those associated with a respiratory irritant, included chest pain, cough, shortness of breath, and irritation of the mucous membranes and of the eyes. The episode occurred in an area approximately 24 km. (15 mi.) long and 2.4 km. (1.5 mi.) wide, surrounded by hills 100 m. (330 ft.) high. Within the area were steel mills, power plants, glassworks, lime kilns, zinc refining plants, a coking plant, a sulfuric acid plant, and a fertilizer plant. Most of the homes and buildings in the area were heated with coal, which added to the pollution load. Later investigation revealed that more than 30 contaminants had probably been present in the atmosphere at the time of the disaster. After checking available data on the medical, meteorological, and environmental factors, it was concluded that the contaminants most likely to have caused the symptoms were sulfur compounds.

The second well-known air pollution disaster occurred between Oct. 27 and 31, 1948, at Donora, Pa. During this period 20 persons died and 6,000 became ill. Like the Meuse Valley, Donora was heavily industrialized and located in a topological basin. Meteorological inversion and stagnation occurred while large amounts of various air contaminants were being discharged. Investigations indicated that, while no single substance was responsible for the disaster, the adverse effects could have been produced by a combination or summation of the action of two or more of the contaminants. Oxidation products of sulfur dioxide, together with particulate matter, were significant factors.

At Poza Rica, Mex., on Nov. 24, 1950, when the third much-publicized air pollution episode occurred, 22 persons died and 320 were hospitalized. In this incident, a sulfur removal unit used in petroleum refining had been put into operation on Nov. 21. Although during the "shakedown" period an overflow of amine solution had partly plugged the gas lines to the pilot lights on the flare stacks of the unit, this had gone unnoticed by operating personnel, and on Nov. 24, at 2:00 A.M., operation of the plant at full-rated capacity was begun. By 2:30 A.M. the desired flow rate was reached, but at approximately 4:00 A.M. operational difficulties were encountered, with the probable result that large quantities of hydrogen sulfide were vented unburned to the atmosphere. Meteorological data indicated that a pronounced low-

altitude temperature inversion prevailed at the time. The onset of acute illnesses began at 4:50 A.M. and ended at 5:10 A.M., and the victims were all directly downwind of the unit's vent stacks. The onset, symptoms, and pathological findings were consistent with hydrogen sulfide poisoning. Unlike other acute air pollution incidents, a single toxic substance and source were responsible.

In London, between Dec. 5 and 9, 1952, the fourth and largest air pollution disaster occurred. Most of the British Isles were covered by fog, and there had been a temperature inversion. Characteristically the illnesses were sudden in onset and tended to begin on the third or fourth day of the episode. In the one-month period that followed, the number of deaths in Greater London in excess of normal totaled more than 3,500. The peak death rate occurred on Dec. 13, when it was 2.5 times as high as the norm for the preceding five years for that time of year. Although increased mortality was experienced by every age group, persons in their 60s and 70s had the highest increase. More than 80% of the deaths occurred among persons with known heart and respiratory diseases. Although this was the first air pollution episode in which air sampling was conducted before, during, and after the event, the general nature of the pollution problem was such as to preclude development of specific cause-and-effect relationships. Autopsy examinations did not reveal any characteristic mode of death other than evidence of respiratory tract irritation.

Confined Space Pollution.—Contaminants may occur or build up in enclosed spaces such as houses, factories, office buildings, and space vehicles. Volatile liquids and substances that are gaseous at normal temperatures are more likely to produce contamination than solids, although even solids have measurable vapour pressures and, if toxic enough, can produce pollution problems in poorly ventilated places. Finely divided liquids and solids dispersed into confined spaces must also be considered as potential pollutants, as must unusual releases of all types of energy. With the increasing development of chemical products and devices for use in the home, the potential for accidental poisoning—both acute intoxications and long-term chronic effects—has risen. Health hazard evaluation and control of confined space contamination have been developed mainly in industry.

Wherever matter is handled or energy is utilized or converted, some of the substances, by-products, or energy will escape into the surrounding environment either directly or indirectly. The toxicity or detrimental effects of atmospheric contaminants is closely related to the amount that may occur in spaces occupied by workers, and many occupations have been found to have injurious effects on the physical health of workers. Fortunately, the number of chemical, physical, and biological agents to which any one worker may be exposed at any one time is often limited, and only one of these may be of critical significance. Thus, based upon human experience, measurable physiological responses, and toxicological data derived from test animals, lists of permissible concentrations have been developed to serve as a guide in making health hazard evaluations of industrial environments. The most widely used of these is the list of threshold limit values published by the American Conference of Governmental Industrial Hygienists, which names approximately 320 substances that may occur in the work environment as gases, vapours, mists, fumes, or dusts. The concentrations refer to average values for a normal work exposure of eight hours a day, five days a week. They represent levels of atmospheric contamination to which it is believed that nearly all workers may be repeatedly exposed, day after day, without adverse effects. These threshold limit values are reviewed annually. Depending upon the physical state of the substance that may occur as a contaminant, threshold limit values (see Table) are expressed as parts of vapour per million parts of air (ppm), milligrams of substance per cubic metre of air (mg/m^3), or millions of particles per cubic foot (mppcf).

These limits must be combined with considerations of many other factors and should be applied and interpreted only by qualified persons. They are primarily applicable to single-substance exposure of workers in industry and are not intended for use in

Threshold Limit Values of Common Industrial Contaminants

Substance	ppm	mg/m ³	mppcf
Acetone	500	1,200	—
Benzene	25	80	—
Carbon monoxide	50	55	—
Ethyl alcohol	750	1,400	—
Hydrogen sulfide	20	30	—
Mercury	—	0.1	—
Ozone	0.1	0.2	—
Zinc oxide fume	—	5	—
Asbestos dust	—	—	5
Talc dust	—	—	20
Portland cement dust	—	—	50

the evaluation or control of community air pollution or in estimating the toxic potential of continuous exposures. When two or more hazardous substances are present, their combined effort rather than that of either individually should be considered. Mathematical approximations of threshold limit values for mixtures can be made but must be applied with caution since synergism or potentiation may occur in the organism.

Besides threshold limit values, emergency exposure limits have been developed by the American Industrial Hygiene Association for a few common contaminants for exposure periods ranging from 5 to 60 minutes. Exposure concentrations permissible for short periods are normally, of course, several times greater than those for long-term work routines. There are, however, important exceptions in which ceiling values no more than 1.25 to 3 times the 8-hour-day, 40-hour-week threshold limit values should be enforced, even for quite short exposure periods.

Other limits of exposure relative to radioisotopes, noise levels, heat stress, and various ionizing and nonionizing radiations have also been developed for industrial application.

Of all of the areas of concern regarding environmental pollution, most success has been achieved in establishing reasonable levels of exposure for workers in enclosed spaces. There have been developed exposure limits for chemicals and dusts, damage risk criteria, and audiometric techniques for controlling noise exposures, heat stress indices for hot work, and various other guides, which when intelligently applied not only protect the health of the worker but permit him to make beneficial use of the resources that are being continually released by an expanding technology.

LEGISLATIVE CONTROL MEASURES

Efforts to control environmental pollution have met with varying degrees of success and have been limited to some extent by problems of legislative jurisdiction. Frequently the problems of pollution require a many-faceted attack.

Although many communities have enacted effective legislation to control pollution, the problem continues. For example, Chicago began to be concerned about smoke as early as 1874, when a citizens' association became interested in the problem, and in 1881 the Chicago City Council adopted the first smoke ordinance in the United States. While this and similar ordinances successfully reduced pollution from smoke, the problem of pollution persisted from other contaminants, such as noxious motor-vehicle fumes. Moreover, polluted air or water does not respect city, state or provincial, national, or even continental boundaries. Smoke emanating from the steel mills of Gary, Ind., less than 30 mi. (48 km.) from Chicago but in another state, cannot be controlled by Chicago's City Council or even by the Illinois state legislature. Also, the industries of all the other cities (and states) that border Lake Michigan contribute to what has become a serious water pollution problem. In Europe, long rivers that flow through many countries present similar problems of pollution and legislative control.

Legislation to abate pollution generally falls into two categories: (1) banning the use of certain types of fuels and inefficient equipment and (2) restricting limits of emissions and the density of contaminants. Although many communities have enacted legislation dealing with pollution, national legislation has assumed increasing importance, as evidenced by passage of the Clean Air Act (1956) in England and, in the United States, by the adoption of the Clean Air Act of 1963 (amended 1965) and the Water Quality Act of 1965. The regional abatement plan adopted for

the Ruhr River in West Germany concerns a cooperative venture aided by the federal government and involving compulsory membership of the industries and municipalities that use the Ruhr water supply. The tax-deductible effluent fee paid by the 1,200 members of the Ruhr River Valley Association provides funds for operating more than 100 sewage-treatment plants serving about 1,700 sq.mi. (4,403 sq.km.) of the river's drainage area.

Further efforts have been made to control pollution on an international basis. In June 1964 experts from the United States and Japan and from 17 European countries (members of the Council of Europe) met in Strasbourg, France, to plan a common offensive against air pollution, and in August of the same year the second International Conference on Water Pollution Research was held in Tokyo. Studies begun in 1965 with the introduction of the International Hydrological Decade promised to develop further international cooperation in the area of water resources development and control.

POLLUX, JULIUS (2nd century A.D.), Greek scholar and rhetorician of Naukratis in Egypt, was the author of an *Onomasticon*, a Greek thesaurus of terms. The emperor Commodus appointed him to a chair of rhetoric in Athens. The *Onomasticon*, his only surviving work, is in ten books. It is incomplete, having undergone abridgment and interpolation in antiquity. The work contains rhetorical material (e.g., collections of synonyms and compounds) and technical terms pertaining to a wide variety of subjects, as well as citations from literature. The material on music and the theatre is of special interest. Editions include that by W. Dindorf (1824) and by E. Bethe in the Teubner *Lexicographi Graeci*, three volumes (1900–37). (G. Do.)

POLLUX, in astronomy, the brightest star of the zodiacal constellation Gemini (q.v.). This reddish first-magnitude star and the slightly less bright blue star Castor mark the heads of the celestial Twins, whose feet are in the Milky Way across from Orion. Pollux is 35 light-years distant and is intrinsically 33 times as luminous as the sun. The Twin stars are not far from overhead in the early evenings of early spring for observers in middle northern latitudes. (R. H. BR.)

POLO, MARCO (1254–1324), Venetian traveler, whose descriptions of his journey across the world from Venice to China and back, and of his experiences in the vast dominions of the Mongol emperor Kublai, make one of the greatest books of all time. This remarkable work, *The Book of Marco Polo, Citizen of Venice, Called Million, Wherein Is Recounted the Wonders of the World*, is a forerunner of scientific geography. Its author was the first to inform the West of the extent and power of China, and the first to give an intelligible account of the ways thither. He made known a host of places hitherto hidden from European cartographers. Granted the prejudices of his age, in which, for instance, Christians and Muslims knew each other's faith only in travesty, his judgments reveal an open mind. The value of his observations on the events of his time is recognized by modern Orientalists, and the problems posed by variations in the reading of the different manuscripts of his book have inspired much scholarly research in the attempt, still in progress, to reconstruct the original text. Yet *The Book of Marco Polo* did not become a widely read work until the 19th century, since when it has been translated into many languages.

Journey of Niccolo and Matteo Polo.—Marco Polo was born either at Venice, or perhaps at Korcula (Curzola), a Venetian outpost on an island off the Dalmatian coast, in 1254. His father, Niccolo Polo, and his father's brother Matteo were members of a noble family of Dalmatian origin, though we do not know whether their remote forebears were Italian or Slav. When Marco was still a child, his father and uncle set out for the East; they were

ROUTES TRAVELED BY MARCO POLO BETWEEN 1271 AND 1295

merchants and had commercial interests in Constantinople. From there they sailed in 1261 to pursue their trading operations at Sudak, a Venetian colony on the southeastern coast of the Crimea, where they seem to have had a branch of their business. From there they went on to Sarai (Chaucer's "Sarra in the land of Tartarie"), the capital of the western Kipchak horde whose prince, Berke (Barka Khan), warmly received them. They remained in Sarai for a year. The outbreak of war between Berke and Hulagu, the Mongol ruler of the Persian region of the former Abbasid Arab Empire, blocked their way back to Europe, so they chose a safer but much longer route round the Caspian Sea and on to Bukhara in central Asia where they made another prolonged halt, this time for three years. While they were at Bukhara some envoys returning from a mission from Hulagu to his brother Kublai, the Great Khan of China, persuaded the brothers to accompany them to Kublai's court at Khanbaliq, the modern Peking (Peiping), or Shang-tu, the Xanadu of Samuel Coleridge's poem *Kubla Khan*. The extension of the area of Mongol conquest from the Pacific Ocean to the gates of Europe had given this immense tract a political unity and a security along its roads which it had never possessed before, and this circumstance permitted a few enterprising travelers from the West to penetrate behind the barrier which Islam had long raised against European contacts with the Far East. The Polo brothers were among the first Europeans in medieval times to enter China. Kublai welcomed them and asked them many questions about Christendom. They stayed for several years at the court of the Great Khan but unfortunately left no record of their experiences there. At last the Great Khan allowed them to return to their home and gave them letters to the pope asking him to send learned missionaries to instruct his subjects in the tenets of Christianity, for Kublai's attitude toward the great religions was still experimental and fluid. The Venetians once more took the road and traveled over the length of Asia to Acre (Akko) where, in 1269, having learned that no new pope had been elected

since the death of Clement IV, in 1268, they decided to return to Venice, there being no pope to whom they could deliver their letters in Rome.

Marco Polo's Journey.—Two years passed before the brothers resolved to start again on their travels, and this time they took with them Niccolo's son Marco, then 17 years old. They prudently armed themselves with letters justifying their delay in Europe, but hearing after they had arrived on the Syrian coast that the papal elections had taken place and a new pope, Gregory X, had been enthroned, they returned to Italy to carry out Kublai's mission. Gregory could supply only two Dominicans, men poor in spirit who soon turned back, glad to be relieved of so arduous an apostolate. In 1271 the brothers left Ayas (Yumurtalik, known as Ajuzzo or Laiazzo to the Italian merchants), a small town on the Gulf of Iskenderun, and rode overland by Yazd and Kerman to Hormuz on the Persian Gulf with the intention of taking ship to China. For some reason unknown to us the party abandoned its plan for a sea voyage and stolidly turned northward and made its way through Persia to Balkh, and from there ascended the upper Oxus (Amu-Darya) to Wakhan and crossed the plateau of the Pamir, a name which Marco was the first European to record. They then descended from the high plateau and journeyed through Kashgar (Shufu), Yarkand, and Khotan (Ho-t'ien), regions which remained closed to Western knowledge until the 19th century. From Khotan they passed near Lop Nor, crossed the Gobi Desert and entered China by way of Su-chou (Kiuchüan) and Ch'ang-an (Sian). At length, in 1275, after a journey lasting three years, they presented themselves to Kublai Khan at his summer palace at Shang-tu.

Marco records that he made rapid progress in the Great Khan's favour; he studied the Mongol language and was entrusted by the emperor with various missions to different parts of his realm. As he became an astute man of business, Marco made careful notes of his itineraries, the state of the cities, the customs of the peo-

ple, and the kinds of crops and other products. He would have done this not merely to satisfy Kublai's thirst for knowledge but also as part of his duties as an official charged, so it would seem, with administrative tasks. Although most of the place names which he records have since been verified, and much of his narrative, which would have appeared so strange to his European contemporaries, confirmed in the light of modern research, nevertheless many difficulties remain in elucidating incidents mentioned in the book. For instance, Marco narrates that he was for three years governor of Yangchow (Chiang-tu), a high improbability for a European, even if it were chronologically possible. In the face of such a statement we may make reasonable allowance for his, or his scribe's, embroidery of a good story, and where Marco writes "governor" we may read some less exalted term, perhaps agent or deputy. Another occasion on which Marco seems to overpass the boundaries of the credible is when he credits his father and uncle with ensuring the fall of the city of Hsiang-yang, during a war against south China, by the construction of siege mangonels, a story beset by difficulties of dating. Marco tells us that he visited places as far afield as Cochinchina, Burma, and India during his service with the Great Khan. Here we must distinguish between places which he actually visited and those which he describes from information derived from others. He does not tell us whether his two relations went with him on these journeys.

The Polos had now been 17 years with Kublai; though they had prospered in his service, they began to dread what might happen at his death, for there was no dynastic continuity in Mongol rule. The Great Khan liked them, or found them useful, and was unwilling to let them go, and the opportunity to return came by chance. In 1286 Arghun, Mongol ilkhan, or regional ruler, of Persia, a grandson of Kublai's brother Hulagu, lost his favourite wife, a Mongol lady, and sent envoys to China to bring back another of her tribe to fill her place. As the overland route from Peking to Tabriz was menaced by war, Arghun's agents prepared to return by sea. Having met the Venetians and desiring to profit from their experience, they begged Kublai to send the Polos in their company. The Great Khan consented; he ordered junks to be fitted out for the voyage, and he gave the Polos friendly messages to the potentates of Christendom, including the pope and the kings of France and England. Early in 1292 the mission sailed from Zaitun, probably the modern Chin-chiang in Fukien, then one of the chief Chinese ports for foreign trade, and navigated a course which took them through the straits of Singapore and Malacca to the Nicobar Islands, Ceylon, Malabar, and on, hugging the coast where they could, to Hormuz, where they arrived in 1294. The long voyage involved vexatious delays on the coasts of Sumatra and south India. Some tragedy, possibly a disease such as scurvy, caused the death of many on board, including two of the envoys and most of their suite, but the young bride and the three Venetians survived. Arghun Khan had died in 1291, before the party left China; the bride thereupon married his son, Ghazan Khan. After nine months at the Persian court the Polos started on the last lap of their journey, traveling from Tabriz over the mountains to Trebizond (Trabzon) where they took ship for Constantinople and Venice. They arrived home after an absence of 25 years. Giovanni Battista Ramusio of Treviso, the Venetian diplomat who composed an edition of Marco's book two centuries later, mentions that the travelers' relations failed to recognize them. They were said to have brought back much wealth, though Marco did not die a rich man by the standards of his time.

We next hear of Marco Polo as a naval officer, a *sopracomito* or gentleman commander of a galley in a Venetian fleet commanded by the admiral Andrea Dandolo. War had broken out between the republic and Genoa, and a Genoese fleet under Lamba Doria had sailed into the Adriatic on a raid into Venetian home waters. In a battle off Curzola (Korcula) Island in Sept. 1298 the Venetians were routed and, according to one source, Marco was taken prisoner, though he himself is silent on the circumstances of his capture. Another source suggests that he was captured in an earlier clash with the Genoese. Whatever the cause of his imprisonment at Genoa, the victors treated their distinguished captive with kindness; his captivity lasted less than a year and he was back in

Venice by the summer of 1299.

His few months as a prisoner of war were the immediate cause of his book. While he was in prison he met a fellow captive named Rustichello, or Rusticiano, of Pisa, an able writer of romances who, in 1271, had compiled *Meliadus*, a collection of chivalric romances, written in *langue d'oïl*. To him Marco dictated the story of his adventures and Rustichello wrote it down in the same language in which he had written *Meliadus* and often with the same turns of phrase. The question of the extent and nature of Rustichello's influence on the text of Marco Polo's narrative is one of extreme complexity. Modern students of Marco Polo's book tend to limit the importance of Rustichello's interventions and to regard his share as simply the conversion of Marco's dictation into the stylized language of romance. It is generally accepted that Marco did not confine himself to drawing upon his memory but made reference to written material which he may have had sent from Venice for his use. As has been mentioned, he took abundant notes while he was in Kublai's employ, and these may well have formed the basis of his book.

We learn little of Marco Polo's life after his return from Genoa. At his death in Venice on Jan. 8, 1324, he left a wife Donata, and three daughters, Fantina, Bellela and Moreta. On the day of his death he made a will and was buried, according to his wish, in the church of S. Lorenzo. The only architectural reminder of his existence—his tomb was obliterated by subsequent rebuilding of the church—is the court in which his house once stood. The family died out before 1500. There are several portraits of Marco Polo, none taken from life. The noble status of his family is documentarily proved; the family shield is depicted in a manuscript of 1424.

Considering the wealth of new geographical information recorded by Marco Polo it is disconcerting to discover how slow were contemporary cartographers to embody this information in their maps. It must however be remembered that Marco Polo's generation regarded his descriptions primarily as a collection of marvels. It did not occur to the map makers to abandon traditional beliefs and to apply scientific criteria to geographical discoveries. The first map in which Marco Polo's influence is abundantly evident is the great Catalan Atlas of about 1375 which drew freely upon his book for the topography of central Asia and the Far East. It was not until the age of the great ocean voyages of the later 15th century that Polo's material was widely used. Columbus, for instance, whose destination was Polo's Cathay, heavily annotated a printed copy of Ramusio's Latin version in his possession. The popular ascription to Marco Polo of the introduction to the West of gunpowder, the mariner's compass, and block printing is now discredited.

The Texts.—In different countries the book of Marco Polo has customarily received different titles. In Britain it has been persistently called *The Travels of Marco Polo*, while the Italians insist on calling it *Il Milione* and apply this title both to the book and to the author. Indeed the significance of this curious title has given rise to much conjecture, though with inconclusive result. According to some, Marco, and hence his book, were thus called by his fellow citizens by reason of the exaggerated magnitude of the wonders which he recounted. Later opinion advances the possibility that *Milione* may not be a nickname after all, but rather Marco's real name, a variant of Emilio.

Over 140 manuscripts of *The Book of Marco Polo* have been located, and these fall into groups according to their dependence on the following key texts: (1) an early 14th-century version, written in Italy, in italianate French, and first published in Paris in 1824 (not without errors of transcription) by the Société de Géographie of Paris as *Voyages de Marco Polo in Recueil de Voyages et de Mémoires*, i, and known as the "Geographic" text; (2) another early 14th-century version written in French and printed by J. P. G. Pauthier in Paris, 1865, as *Le Livre de Marco Polo*; (3) a version in Tuscan Italian, dated perhaps 1305 and printed by G. B. Baldelli Boni in Florence in 1827 as *Il Milione di Marco Polo*; (4) a version in Venetian Italian, early 14th-century, printed in Studi Romanzi, iv, Rome (1906); (5) a Latin version by Fra F. Pipino of Bologna, dated between 1307 and 1314, and

made from (4); (6) an Italian version, edited by G. B. Ramusio, printed in *Navigazioni Viaggi*, ii, in Venice (1559), and derived from (1) and from another manuscript, possibly (7); (7) a Latin version in the cathedral chapter house at Toledo, written probably in Italy about 1470, a translation of a text older than (1) and known as the "Z" text from the surname of Cardinal F. X. de Zelada (1717-1801), a papal secretary of state who gave the manuscript to the library. Of these seven manuscripts, (1), (6), and (7) are usually held to be the most important.

The original text that Marco Polo dictated to Rustichello was almost certainly written in French. The work is divided into two parts: the first a narrative of the Polos' two journeys, the second a series of descriptions of administrative, economic, and political facts and notable occurrences in the lands which he describes. The original text is believed to have been destroyed, and the quest for a text as near as possible to the original has taxed the ingenuity of scholars ever since W. Marsden first applied the critical method in his translation, *The Travels of Marco Polo* (London, 1818). Sir Henry Yule's magnificent translation, *The Book of Ser Marco Polo*, published in London in 1871 (third edition, revised and augmented by H. Cordier, London, 1903), though slightly marred by lapses into somewhat precious English, remains the most compendious source of information on Marco Polo. This was followed by H. Cordier's *Ser Marco Polo, Notes and addenda to Sir Henry Yule's edition* in 1920. Both Yule's edition and that of A. J. H. Charignon, *Le livre de Marco Polo* (published in Peking in 1924-28), a modern French translation of Pauthier's text of 1865, suffer from having been based on texts of unascertained authenticity. The first to present a reconstructed, authenticated text was L. F. Benedetto in his *Marco Polo, il Milione* (Florence, 1928); Italian translation by L. F. Benedetto (Milan, 1932); English translation by A. Ricci with introduction by Sir E. Denison Ross (London, 1931). Textual reconstruction was carried a stage further with the discovery by Sir Percival David in Toledo in 1932 of the "Z" text, published by A. C. Moule and P. Pelliot in London in 1938 as *Marco Polo, the Description of the World*, of which volume i consists of an English translation, with critical apparatus, of the "Geographic" text together with collated passages drawn from other important manuscripts, and volume ii of a transcription of the "Z" text. Among more recent editions of outstanding merit is a Polish translation by A. L. Czerny, with notes by M. Lewicki, *Marko Polo, opisanie swiata*, published in Warsaw in 1954.

BIBLIOGRAPHY.—There is a large literature of shorter studies concerned with Marco Polo; e.g., G. Orlandini, "Marco Polo e la sua famiglia," *Archiv. Veneto-Tridentino*, ix (1926); R. Almagià, "A proposito di recenti studi su Marco Polo e i suoi viaggi," *Riv. Geogr. Ital.*, vol. lxii (1955); A. C. Moule, *Quinsai, With Other Notes on Marco Polo* (1957). The 700th anniversary of Marco Polo's birth was marked by several popular works and special articles including the symposium *VII centenario della nascita di Marco Polo* (1955). (R. L. H.)

POLO is played on horseback with stick and ball, and takes its name from the Tibetan *pulu*, "ball." The earliest records of polo are Persian; there is evidence that it was played in the time of King Darius the Great (522-486 B.C.). Persian polo is described in Sir Anthony Sherley's *Travels to Persia* (1613). From Persia it spread to Constantinople, and eastward through Turkistan to Tibet, China and Japan, and from Tibet to India, where it flourished throughout the Mughal dynasty (early 16th to mid-18th century). Then for 100 years there are no records of it in India proper though the game continued to be played in the feudal states on the northwestern and northeastern frontiers.

The first Western polo players were British tea planters in Assam, who learned the game in nearby Manipur, on the Indo-Burmese border. They formed the first European's polo club in 1859 at Silchar and drew up the first rules. The Calcutta Polo Club was formed in the early 1860s. In 1869 the 10th Hussars started to play polo in England after reading an account of the game in India. In 1871 the first recorded match took place on Hounslow Heath between the 9th Lancers and the 10th Hussars, with eight players to a side; in 1873 the numbers were reduced to five and in 1882 to four. The Hurlingham Polo Association, which be-

came the leading association in Great Britain, was founded in 1874. Polo was first played in the United States in 1883 and the U.S. Polo Association was founded in 1890.

The Game.—Polo is played with four players on each side. The small light ball is made of willow or bamboo root and is not more than 3½ in. in diameter, weighing between 4½ and 4¾ oz. The stick is made of cane and is from 48 to 54 in. long. It has a narrow wooden head measuring 8½-9½ in. which is set on it at a slight angle. The ball is struck not with the forward face (as in croquet) but with the long side of the head. The total weight of the stick is about one pound.

A full-sized polo field is 300 yd. in length by 200 yd. in width, if unboarded; and 300 yd. in length by 160 yd. in width, if boarded. The goals must not be less than 260 yd. apart, and each goal is 8 yd. wide. The object of the game, as in so many others, is to pass the ball between the goalposts. A match lasts about an hour, divided into periods of play known as chukkas (chukkers; from the Indian word denoting one full turn of a wheel); intervals between chukkas, when ponies are changed, are of 3 min., with 15 min. at half time. Six chukkas of 7½ min. are usual in a full match. Ends are changed every time a goal is scored. The players are designated no. 1 and no. 2 (forwards), no. 3 and no. 4 (backs).

The two mounted umpires, one for each side of the field, consult together after each infringement and impose a penalty only if they agree. If they do not agree a decision is given by the referee, who watches the game from the sidelines or the grandstand. The referee also gives judgment on any question of the rules which arises outside the actual play.

The most important rules are those concerning the safety of men and ponies. Chief of these are the crossing and riding-off rules. No player may cross the line of another in going for the ball, and the last man to strike it has right-of-way. Other players may legitimately "ride him off," however. This means impinging, pony to pony, on a converging course in the manner of a shoulder charge in football. Hooking of sticks is also permitted. In a game played at the gallop, hazards are equally shared; consequently the rules are carefully observed, such transgressions as occur being mostly accidental.

The American game, borrowed from the British, developed independently for 30 years, with certain fundamental differences from the game as played elsewhere. Some of these differences, combined with the U.S. handicapping system, dating from 1891, and the ready supply of suitable ponies, went far toward establishing an American world supremacy.

Attack has always been stressed in play in the U.S. After the U.S. won its first victory in the Westchester Cup international series with England in 1909, the rules of the two countries were assimilated. The U.S. adopted the English rule permitting the hooking of sticks, and the English abandoned the offside rules and adopted the handicap system. After World War I England followed the U.S. lead in abolishing the size limit for polo ponies (see below).

Players.—All polo players competing in tournaments are given a handicap by the governing bodies in their own countries. By international agreement these handicaps, in effect a ranking list, are accepted in all other countries. The system is based on a national estimate of the number of goals a player is worth to his side. For instance, a handicap of 10 goals, which is the highest ever given, implies a player of the greatest talents and in constant practice; such a handicap is supportable only by a man who plays or practices polo daily. In modern conditions most 10-handicaps are held by South American players. A few are held in the United States. The difficulty of obtaining constant practice in Britain, and the temporary reduction in the number of tournaments in India and Pakistan, have made 10-goal players from these countries rare. The lowest handicap possible is -2.

Handicaps are applied in matches by adding together the ratings of the players on either side; the lesser team total is then subtracted from the greater, and the resultant number of goals is allowed to the weaker side as a "start." The idea of handicaps originated in the United States as long ago as 1891 and, besides

making play more interesting, had the immediate effect of raising standards with surprising speed. Not only did the handicap idea enable less-experienced and younger players to take part in the same matches as top-class performers, but it compelled the latter always to play at their best and hardest. Handicaps also serve to grade the standard of a polo tournament. An "8-goal tournament," in which no team with a greater total handicap than 8 may compete, implies competence only, since the average rating is 2 goals per man; a "12-goal tournament" indicates fair quality performers; a "20-goal tournament," the highest class.

Polo is an expensive game. Behind each player must be an organization of ponies and grooms, the maintenance of which involves continuous expenditure on feed, equipment, and wages in and out of season. Transportation from tournament to tournament is likewise costly. Not surprisingly, the game has always depended on the participation of wealthy men. However, there have always been, in every polo-playing country, a small proportion of players for whom polo has provided a livelihood, some as the permanent guests of team captains. Others, if very fine horsemen, are employed in buying and training ponies: this work keeps them in constant practice and develops their game so that they are always sure of their place in a team. Such professional players traditionally were recruited from among the British officers of the old Indian Army. Latterly, professional players have been drawn from such diverse sources as North American cowboys, South American gauchos, and the princely families of the Indian subcontinent.

A polo player requires a strong seat on a horse, a good eye for hitting a ball, a powerful wrist, dash, determination, great physical stamina, and experience. The latter is so important that, although polo is the most strenuous of summer games, few players reach their best form until they are aged 40 or more, and the prime of life for polo is between 45 and 55.

Ponies.—The term "polo pony" has become a misnomer. There is no longer any height limit on the mounts used in polo and the only criteria for selecting a pony are that it should be both large enough to carry its rider without loss of pace and small enough to be handy. Obviously it is easier to hit a moving ball from the back of a small mount than from a large one. Obviously, too, a small animal is the more maneuverable and can turn more quickly. On the other hand, the longer the stride the greater the speed, and the stouter the build the greater the weight that can be carried. Most polo ponies are really small horses 15–15.2 hands high and some of them are taller. (A horse under 14.2 hands is defined as a pony.)

In the past the size of the ponies was restricted. In Manipur the game was played on ponies of 12 hands. The English, being larger than the Indians, raised the limit to 13.2 hands, then to 14.2 hands, and, finally, in 1919, abolished it altogether to conform with the earlier decisions (by 1918) of the United States and Argentina. Polo ponies are predominantly grade Thoroughbreds, descending from a series of racehorse sires bred with mares of different local bloods. In the East the mares were chiefly Arabian; in Great Britain, one of the native pony breeds; in the United States and Australia, free-running ranch ponies; and in Argentina, the hardy native pampas pony.

Because the game is very hard on the ponies—they may gallop as much as three miles in each chukka and the sudden stopping and turning imposes considerable strain—no pony plays two successive chukkas except in an emergency, and each player generally rides at least three ponies in the course of a six-chukka match. With careful training ponies develop keenness and skill and show great cleverness in anticipating the run of the ball and in placing themselves at the best distance from it for the rider to make his stroke. A pony needs sagacity, a nerveless temperament, quick reflexes to respond instantly to his rider's aids, very sound legs for galloping on hard grounds, and great muscular power so as to be able to stop and turn from full gallop.

Injuries to ponies and riders are few. The ball is too light to inflict much damage; sticks are less stoutly made than appears to be the case and even a vigorous accidental blow is unlikely to break a bone.

Championship and International Polo.—Before World War II the two most important trophies for polo were the Hurlingham Champion Cup, an international contest inaugurated in 1876, and the Westchester Cup, a contest between Great Britain represented by a Hurlingham team, and the United States represented by a Meadow Brook team, inaugurated in 1886. Great Britain won in 1886, 1902, and 1914; the U.S. in 1909, 1911, and 1913, and in 1921, 1924, 1930, 1936, and 1939. Argentina and the United States met four times, 1928–50, for the Copa de las Americas, won by the U.S. in 1928 and 1932, and by Argentina in 1936 and 1950; and Mexico and the United States met three times, once in 1941 and twice in 1946, for the General Manuel Ávila Camacho Cup, the U.S. winning each time.

After World War II it looked as if polo in England was finished. But the remnants of the prewar players were determined to carry on. The small Ham Club was the first to start, and then Viscount Cowdray began a great revival with the Cowdray Park Polo Club. Other old clubs revived and new ones started, and some began to maintain trained ponies for hire.

In the second half of the 20th century Argentina and the U.S. had become the leading polo-playing countries, followed by South Africa and England. High-class polo had developed rapidly in Mexico and in Chile, Colombia, and in other parts of South America as well. Polo has flourished in India and Pakistan and players appear regularly in English teams. India has sent a touring side to Great Britain and the British Army has sent a side to India.

In the United States, interest in polo increased markedly after World War II, with play in the seven circuits: Northeastern, Southeastern, Central, Mid-States, Northwestern, Southwestern, and Pacific Coast, and intercircuit and national championships. One of the world's finest polo centres was established by Paul Butler at Oak Brook, near Chicago, and another by Robert A. Uihlein at Uihlein Field, near Milwaukee. In 1963 these fields were the scenes of the first international competition between the United States and the United Kingdom since 1939. Cowdray Park of the U.K. defeated a Milwaukee team in two matches for the Robert A. Uihlein International Cup and defeated Tulsa, the U.S. Open Champions, in the Butler National Handicap.

Organization.—Outside the United States the governing body of polo is the Hurlingham Polo Association. The associations of many other countries and regions are affiliated to it and have representatives on the council. In the 1960s the following were members: India, Pakistan, Assam, New Zealand, Australia, South Africa, Rhodesia (embracing both North and South), Kenya, Nigeria, Malaya, Jamaica, Malta, Cyprus, Ireland (north and south), Accra, Aden, Tangier, Hong Kong, and the Rhine Army Polo Club.

The United States Polo Association is the governing body in American polo.

Polo has been included intermittently in the Olympic Games, the last time being at Berlin in 1936. In some countries, notably Great Britain and the United States, women are allowed to participate and several of them have played regularly in low- and medium-goal tournaments. Popular variants of the game are arena polo, which is played indoors in the winter in North America, and paddock polo, which is played with a soft ball by children in Great Britain.

POLOCK, MOSES (1817–1903), U.S. publisher and bibli-

Player in front is making a nearside backhand shot under the neck of his pony. Note how close the trailing rider's pony is to the front horse as the player tries to get into position to block the shot. Many injuring falls occur during this type of action

A thong attached to the haft of the mallet is wound tightly around the player's wrist so that the mallet is not lost during play. The ball is hit with the side of the mallet

PLAY IN POLO

Player at right is attempting an offside forehand shot on a bouncing ball. Player at left has failed in his attempt to intercept the ball

A nearside backhand save has been successfully made by the player in the foreground. The ball is at far right

Player at left is checking his pony to avoid fouling a player who has just made an offside forehand shot

PLAY IN POLO

Action in the U.S. Open in 1960 at the Oak Brook Polo club, Oak Brook, Illinois. Player at the left has made a nearside backhand shot behind his pony. Teammate, right foreground, has held off opposing player charging in from the right in an attempt to prevent the shot

Player on right has just hit the ball to score a goal

ophile, is chiefly remembered as the first rare-book dealer to devote himself solely to Americana. Born in Philadelphia, Pa., on May 14, 1817, he was apprenticed to the firm of McCarty and Davis, an old Philadelphia house of bookdealers and publishers. Polock succeeded to the ownership of the firm in 1851 and from 1853 the business was conducted under his name. The store was frequented by well-known literary figures of the time.

Notable among his publications was the first collected edition of the works of Charles Brockden Brown (*q.v.*), earliest U.S. novelist, which appeared in 1857. He was also responsible for the first U.S. collection of children's literature; he specialized in books on Benjamin Franklin and George Washington. He became an authority on the early history of Philadelphia and Pennsylvania. Polock died on Aug. 16, 1903.

See W. Brotherhead, *Forty Years Among the Old Booksellers of Philadelphia* (1891); A. S. W. Rosenbach, *Books and Bidders* (1927).

POLONAISE, a dignified ceremonial dance, in 3/4 time. It frequently served, from the 17th to 19th century, to open court balls and other royal functions. Originally a folk dance or warriors' triumphal march, it was adopted by the Polish nobility as a formal march as early as 1573. In its aristocratic form the dancers, in couples, walked around the ballroom in stately procession, with slightly accented steps.

As a musical form, the polonaise was occasionally employed by Beethoven, Mozart, and Handel, and was highly developed by Chopin. The polonaise has been introduced in opera (Mussorgsky's *Boris Godunov*) and ballet (Tchaikovsky's *The Sleeping Beauty*).

POLONIUM, a radioactive element, the first to be discovered by the radiochemical method. In 1898 Pierre and Marie Curie, after finding that the radioactivity of Joachimsthal pitchblende was much greater than could be predicted from the content of uranium and thorium, undertook to extract the substance causing this anomaly. Since the only known property of the hypothetical substance was its radioactivity, the Curies developed and used a new method for separating the various substances in the mineral and measuring the radioactivity of each portion. The Curies quickly found that the activity became concentrated, partly with the alkaline earths and partly with the sulfides precipitated from acid solution. They were soon able to confirm the existence of two new radioelements: one a higher homologue of tellurium, to which they gave the name polonium in honour of Marie Curie's native land, Poland; the other, a homologue of barium, was radium. (See also RADIOACTIVITY.)

The chemical symbol of polonium is Po and its atomic number is 84. Twenty-seven isotopes are known; all are radioactive, some naturally and the others artificially (see NUCLEUS). The isotope discovered by the Curies was Po^{210} , the most important of the isotopes and the one generally referred to as polonium. It belongs to the natural radioactive family of the uranium-radium system, whose members are as follows:

Note: Io is the symbol for ionium, a radioactive isotope of thorium.

The Po^{210} isotope was produced artificially for the first time in 1936 by J. J. Livingood, who bombarded bismuth with accelerated deuterons.

Natural Occurrence and Preparation.—Polonium (Po^{210}) is found in much smaller amounts than is radium in minerals containing uranium. About 2,900 kg. of uranium element are in radioactive equilibrium with 1 g. of radium and 0.22 mg. of polonium (1 curie). It can therefore be estimated that 1,000 kg. of Joachimsthal pitchblende containing 65% of uranium also contains about 0.05 mg. of polonium. Its abundance in the earth's crust is of the order of $10^{-13}\%$.

The half life of polonium is long enough so that it can be ex-

tracted directly from uranium minerals. This process has been used but is of little practical value. Polonium is usually extracted either from radioactive lead, which is a by-product of the extraction of radium from uranium minerals, or from radium D, obtained by washing old radon tubes that contain the long-lived active deposit, radium D+E+F; radium D also may be extracted from old preparations of radium salts. The extraction of polonium from solutions of radium D, as well as the preparation of strong sources (up to about one to two millicuries per square millimetre) of this radioelement, is usually carried out by electrochemical deposition on silver or nickel from a weak solution of acetic ($\text{CH}_3\text{CO}_2\text{H}$), nitric (HNO_3), or hydrochloric acid (HCl). On silver, Po is deposited spontaneously free from RaE and RaD; on nickel, Po and RaE are deposited from hot solution almost free from RaD.

Ponderable quantities of polonium can be produced artificially by bombarding bismuth or lead with neutrons (n) or accelerated charged particles. For example:

When polonium is obtained by neutron irradiation of bismuth in a nuclear reactor, it can be separated from the bismuth by volatilization, either directly by heating the irradiated metal or after enrichment achieved by spontaneous deposition of polonium in a hydrochloric solution on a small quantity of bismuth; the bismuth may be either pulverized or in needle form. One can also dissolve the bismuth in acid solution and co-precipitate the polonium by stannous chloride with tellurium added in the form of telluric acid. Afterward, it is separated from the tellurium by precipitation of the latter from hydrochloric solution by hydrazine or by sulfur dioxide.

Polonium can be purified by extraction from its acid aqueous solutions with tributyl phosphate, diisopropyl ketone, mesityl oxide, dithizone (diphenylthiocarbazone) in chloroform solution, etc. Anodic deposition on gold in dilute nitric acid is recommended in order to obtain very pure polonium. Finally, very pure sources of high density of activity can be obtained by volatilization at red heat, in a quartz tube, of polonium that is drawn along by a current of hydrogen, nitrogen or argon and is collected on a cooled metallic surface or on a plastic pellicle.

Radioactive Properties.—Polonium disintegrates with emission of alpha rays to give radium G, a stable isotope of lead (Pb^{206}). Its half life is 138.4 days. The range of the alpha rays is 3.87 cm. in air at 15°C . and at a pressure of 760 mm. of mercury, which corresponds to an energy of 5,298 Mev. The range in nuclear photographic emulsion is of the order of 21μ and in

aluminum of 22μ . Each alpha particle of Po^{210} produces along its path in air 152,000 pairs of ions. It is estimated that the quantity of polonium corresponding to a saturation current of 1 electrostatic unit (E.S.U.) in an ionization chamber using all the ions produced in the angle of 2π is equal to 1.67×10^{-10} g., i.e., $\frac{1}{1.67 \times 10^5}$ millicurie of Po^{210} . The heat loss per hour of 1 curie of Po^{210} , which is equivalent to the kinetic energy of the alpha rays and of the recoil atoms, is equal to 27.24 cal., which corresponds to 0.143 w. per milligram. The alpha radiation, which is essentially monokinetic, is accompanied by very weak gamma radiation (1.25 quantum of 0.8 Mev per 10^5 alpha particles). Marie Curie and A. Debierne were able to determine directly Avogadro's number by measuring the volume of helium corresponding to a known number of alpha particles emitted by a polonium source. The alpha radiation of polonium can cause the decomposition of water, the ozonization of air, and also can affect photographic plates. It excites the fluorescence of polonium compounds and of glass and quartz plates on which these have been placed. It has a toxic effect on living organisms. A rabbit into which 500 E.S.U. of polonium have been injected wastes considerably and dies a few days afterward. Polonium concentrates itself chiefly in the spleen and in the ganglions. According to the national bureau of standards, the maximum permissible dose for a human being in the mid-1960s was 0.02 microcuries (4.5×10^{-12} per gram).

Physical Properties.—The study of the physical and chemical properties of polonium was restricted for many years to the application of radiochemical methods to very small quantities (of the order of 10^{-11} to 10^{-9} g.) of Po^{210} . Since Po^{210} has been prepared artificially, experiments on the milligram scale have been carried out.

The metal, of 9.4 density, is silver-gray or black. There are two crystalline varieties: α -Po, cubic, and β -Po, rhombohedral; the transition point is about 36°C . The melting point is close to 255°C . Judging by measurements of its vapour pressure, the boiling point is likely to be about 960°C . The speed of vaporization, in vacuum, of polonium deposited in minute quantities on nickel is already measurable at 108°C ., and a heat treatment of 5 minutes at 350°C . releases 90% of the polonium atoms. On platinum, volatilization begins toward 350°C .; on gold it starts at a slightly lower temperature, and on palladium only at 500 – 560°C . The vaporization temperature increases with the time that elapses after preparation. It varies, too, with the method of preparation of the sources and also according to the nature of the gaseous atmosphere in which the volatilization is carried out. The diffusion coefficient of polonium at room temperature in aluminum, iron, nickel, copper, silver, gold and lead is less than 10^{-14} sq.cm. per day. In gold and in platinum it is, at 470°C ., close to 10^{-14} sq.cm. per second. In bismuth the diffusion coefficient reaches the value of 5×10^{-11} sq.cm. per second at 150°C . and 5×10^{-10} sq.cm. per second at 200°C .

Between 1.920 Å and 3.975 Å, 147 rays of the high-frequency spectrum of Po and 48 rays of its arc spectrum have been identified. From these measurements the ionization potential of the neutral polonium atom is estimated at 8.43 v.

Chemical and Electrochemical Properties.—From a chemical point of view, polonium, which is the higher homologue of tellurium and the neighbour of bismuth in the periodical classification, is related to these two elements. It is more metallic than is tellurium. When exposed to air the metal is slowly covered by a yellow oxide film. It reacts with chlorine and bromine and dissolves in acids.

Like tellurium, polonium is tetravalent in its most stable state. The existence of two other valencies, +2 and -2, also is certain; that of valency +6 is probable; an unstable valency of +3 is possible. In its tetravalent state, polonium tends to form complex ions with such anions as chloride, nitrate, phosphate, acetic, tartaric, etc. The yellow ammonium hexachloropolonate $(\text{NH}_4)_2[\text{PoCl}_6]$ is the isomorph of the similar compounds of Te^{4+} , Pb^{4+} , Sn^{4+} and Pt^{4+} .

In the absence of the formation of complexes, polonium compounds have, in a nearly neutral aqueous solution, a strong tendency to hydrolyze with the formation of basic salts and of a yellow

insoluble hydroxide, $\text{PoO}(\text{OH})_2$. This hydroxide, which has colloidal properties, is amphoteric; it dissolves in sufficiently concentrated solutions of caustic soda or potash, resulting in a polonite, Na_2PoO_3 or K_2PoO_3 , that is similar to the tellurites. The oxide (PoO_2), obtained by the action of oxygen at 250°C . on metal or by the thermal decomposition of nitrate, is yellow and has a face-centred cubic structure. The tetrachloride has been prepared by dissolving the metal in hydrochloric acid or by heating the metal with chlorine at 200°C .; and also from PoO_2 with hydrochloric acid. It is of bright yellow colour (m.p. = 294°C .; b.p. = 390°C .). Tetrabromide is bright red (m.p. = 330°C .); dark-gray tetraiodide sublimes at 200°C . with partial decomposition. The solubility of nitrate in nitric acid, even when this is concentrated, is very slight (3.7×10^{-8} mole per litre in HNO_3 7.8N at 25°C .). In dilute hydrochloric acid, polonium forms a black sulfide, PoS , that is insoluble in ammonium sulfide (differing in this respect from tellurium but resembling bismuth). With pyrogallol polonium likewise gives an insoluble compound. Reducing agents such as hydrazine, hydroxylamine or sulfur dioxide in an acid medium bring tetravalent polonium into the bivalent state (by contrast with tellurium, which precipitates in a metallic state). The chloride (PoCl_2) is a red solid that melts at 170 – 180°C . when heated in a sealed tube. Solutions in dilute hydrochloric acid are pink in colour and oxidize rapidly under the effect of the proper alpha radiation of polonium. Dibromide aqueous solutions are purple. Strong reducing agents, e.g., stannous chloride, sodium hydrosulfite, alkaline solutions of hydrazine, etc., reduce polonium compounds to the metallic state (by analogy with tellurium). Polonium in nitric, hydrochloric or acetic solutions 0.1 to 0.5N deposits spontaneously on silver, tellurium, bismuth, nickel and on the less noble metals. Under the action of an electric current polonium is deposited, in acid or alkaline solution, on the cathode in metallic form and partially on the anode, probably as the peroxide, PoO_8 . The normal potential of the Po/Po^{4+} electrode in nitric solution is E_h° (normal potential of a hydrogen electrode at 0°C .) = +0.76 v. In acid solutions, the critical potential of the cathodic deposit is lowered if the electrolysis is carried out in the presence of different reducing agents, e.g., oxalic acid, oxygenated water. The normal potential of the $\text{Po}^{2+}/\text{Po}^{4+}$ couple should be E_h° = +0.91 v. Strong oxidizing agents such as bichromate or ceric salts transform tetravalent polonium compounds into a state of higher valency, most likely +6. The potential of the $\text{Po}^{4+}/\text{Po}^{6+}$ couple in HCl or HNO_3 6N is about +1.5 v. Moreover, polonium forms a volatile hydride, PoH_2 , and polonides with sodium, mercury, lead, beryllium, calcium, zinc, silver, nickel and platinum, which indicates the existence of the anion Po^{2-} . Finally, several organic compounds of polonium that can be extracted with solvents have been prepared: polonium dibenzyl, acetylacetonate, diethyldithiocarbamate, oxinate and dithizonate. Polonium dimethyl, which is volatile at room temperature, is also known.

Applications.—Polonium is used in nuclear physics as a source of alpha radiation that is practically exempt from penetrating rays. Irène Curie and her husband, F. Joliot-Curie, discovered artificial radioactivity in 1934 by bombarding aluminum, boron and magnesium with alpha rays of Po. Mixtures of polonium with beryllium and other light elements are used as sources of neutrons. Polonium also has been used to ionize air, mainly in order to avoid the accumulation of electrostatic charges.

POLONNARUWA, an ancient capital of Ceylon that long lay deserted but has again become a thriving town. It is the administrative centre of Polonnaruwa district in the North-Central Province. Polonnaruwa first became a royal residence in A.D. 368 when the tank of Topawewa was formed, and succeeded Anuradhapura (q.v.) as the capital in the middle of the 8th century. The principal ruins date chiefly from the time of Parakramabahu (1153–86). The most imposing pile remaining is the Lankatilaka Vihara, a building 170 ft. (52 m.) long with walls about 80 ft. high and 12 ft. thick. Many other great buildings have been carefully

excavated and preserved. There is a good rest house.

Modern Polonnaruwa (pop. [1963] 5,921) owes its rise to the restoration, in 1938-42, of the great irrigation tank known as Parakrama Samudra (Parakrama's Sea), which now irrigates more than 18,000 ac. (7,285 ha.) of rice. Road and railway construction have destroyed its isolation, and it is now a market centre of more than local significance.

POLONNARUWA DISTRICT, formerly Tamankaduwa division of Anuradhapura district, had a population (1963) of 104,223, compared with 7,907 in 1931. This increase came about largely through the government-organized colonization of former wasteland now irrigated under the Parakrama Samudra and other large schemes. The principal product is rice; tobacco is also grown. See also **CEYLON: History**. (B. H. F.)

POLOTSK, a town of Vitebsk *oblast* of the Belorussian Soviet Socialist Republic, U.S.S.R., stands on the Western Dvina at its confluence with the Polota. Pop. (1959) 44,308. First mentioned in 862, Polotsk is one of the eight Russian towns known to have existed in the 9th century. It was the seat of an early Russian principedom. Its position on a main route between Russia and the west ensured both commercial importance and a remarkably stormy history. After the 13th-century Tatar invasion, Polotsk fell under the control of the grand dukes of Lithuania. In 1498 the town was granted self-government. After many attacks by Russia, Polotsk was captured by Ivan IV (the Terrible) in 1563, but lost again to Lithuania-Poland under Stephen Báthory in 1579. Russia finally acquired the town by the first partition of Poland in 1772. In 1812 it was the scene of an engagement during the Napoleonic invasion. In World War II German forces occupied Polotsk and severe damage was suffered. After its liberation in 1944 it was an *oblast* administrative centre until 1954. Survivals of the past are part of the ancient walls, the 12th-century cathedral of the Spasov-Yevfrosinyevski monastery and the Sofia cathedral, built in 1044-66 and reconstructed in the 18th century. Modern Polotsk is a local centre, with food processing, light engineering and building materials industries. There are also timber, leather and flax processing works and a brewery. An oil refinery was built to receive oil by pipeline from the Second Baku oilfields. In 1953 a pedagogic institute was established. (R. A. F.)

POLTAVA, an *oblast* (province) of the Ukrainian Soviet Socialist Republic, U.S.S.R., formed in 1937, lies along the left bank of the middle Dnieper and is drained by the Dnieper tributaries Sula, Psël, and Vorskla. Area 11,158 sq.mi. (28,900 sq.km.). Pop. (1959) 1,631,706. It is almost wholly within the forest-steppe zone, only the extreme south lying within the true steppe. Except on the meadows of the Dnieper floodplain, soils are everywhere fertile chernozems (black earths). As a result the natural grass and forest vegetation has been very largely removed by plowing, and soil erosion is serious. Surviving groves of oak or pine cover only 6% of the surface.

In 1959 70% of the population was rural, reflecting the agricultural importance of the *oblast*. The 483,773 urban dwellers live in 12 towns and 21 urban districts. All are small except Poltava (143,097) and Kremenchug (86,569). Agriculture is dominated by grains (wheat and maize [corn]), sugar beet, and sunflowers. *Makhorka* tobacco, potatoes, and other vegetables are also important. Industry is chiefly concerned with processing agricultural produce. Near Kremenchug are reserves of iron ore, as yet little exploited. (R. A. F.)

POLTAVA, a town and centre of Poltava *oblast* in the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the right bank of the Vorskla River, 180 mi. (290 km.) ESE of Kiev. Pop. (1959) 143,097. Although the first documentary reference to the town is in 1174, archaeological evidence shows a town existed as early as the 8th-9th centuries. At first known variously as Oltava, Ltava, or P'ltava, by the 15th century the name Poltava was established. In the 17th century it was the chief centre of a Cossack regiment. In 1709 Peter the Great inflicted a crushing defeat on Charles XII of Sweden outside the town. In 1802 it was made seat of a *guberniya* (province). During World War II it was held by the Germans (1941-43).

Lying in the fertile chernozem zone, Poltava is the focus of a

rich agricultural region and its industries are mostly concerned with processing farm products: flour milling, canning, and the manufacture of footwear. A cotton-spinning mill and knitwear and clothing factories represent the textile industry. Engineering is important, with machine building and locomotive repair works. Poltava is a key railway junction of the Kharkov-Kremenchug and Kiev-Donbass lines. It has pedagogic, agricultural, and agricultural engineering institutes. (R. A. F.)

POLYAENUS (2nd century A.D.), a Macedonian living in Rome as a rhetorician and pleader, was the author of a work entitled *Strategica* (or *Strategemata*) which he dedicated to the emperors Marcus Aurelius and Lucius Verus on the outbreak of the Parthian War (162-165). This work, still extant, is a historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes; it includes also examples of wisdom, courage, and cunning from civil and political life. Comprising eight books (parts of the sixth and seventh are lost) it originally contained 900 anecdotes, of which 833 are extant. Despite its many errors of judgment and fact, its contents have some historical value. Evidently highly esteemed by the Roman emperors, it was handed down by them as a sort of heirloom, and passed to Constantinople, being diligently studied by Leo VI who himself wrote a work on tactics. It was also used by Stobaeus and in the *Suda* lexicon.

See for the text, E. Wölfflin and I. Melber (eds.) in the Teubner series, 2nd ed. (1887); Eng. trans. by R. Shepherd (1793).

POLYANDRY, the system under which a woman is married to several men at the same time (Gr. *polys*, "many," and *aner*, *andros*, "man"). Polyandrous institutions include cases in which (1) children recognize more than one man as having the status of true father; (2) a woman bears legitimate children to several different fathers in succession; (3) a legitimately married woman regularly cohabits with several men, none of whom rate as father to her children; and (4) a single legitimate husband allows other men sexual access to his wife. It is debatable how far any of these varieties may properly be described as polyandrous marriage.

Type 1 occurs in Ceylon, parts of India, and Tibet; the fathers in question are usually, but not always, full brothers (in the latter case called adelphic or fraternal polyandry). An unusual version was reported from the Lele of the former Belgian Congo, where certain women are regarded as common wife of all men in the village. The child of such a woman is a "child of the village" and has a special exalted status. Type 2 is strictly polyandrous only if the successive fathers simultaneously have the status of husband, as seems to be the case among the Toda (*q.v.*) of south India and among certain peoples of northern Nigeria. Such cases may be hard to distinguish from those in which each child is born of a different marriage separated from the last by a divorce. The classic example of type 3 is that of the Nayar (*q.v.*) of south India. Formerly every Nayar girl, before attaining puberty, went through a form of marriage with one husband designated by astrology. After three days the marriage was dissolved and the husband returned to his home. The wife then took visiting mates who had a recognized status but were not regarded as the legal fathers of her children. If she had several such mates at one time they cohabited with her but did not reside with her. In this matrilineal society the initial marriage ceremony serves to make a woman's children legitimate, but these children belong to the matrilineage (*taravad*) of the mother; the social status of father is repudiated altogether.

Polyandry of type 4 includes wife lending, which may be simply an expression of hospitality and which serves a purpose among families liable to be separated over long periods, as among the Australian aborigines and the Eskimo. Type 4 also includes cicisbeism (male concubinage): the woman has only one legal husband and her children have only one legal father, but her other sexual partners have a recognized and respectable status. Institutions of this kind have occurred sporadically throughout history: Caesar is a witness for the ancient Britons; Herman Melville for the Marquesas islanders; about 1716 it was fashionable at the court of Vienna. The distinction between cicisbeism, slavery, and prostitution is not always easy to draw (see **CONCUBINAGE**; **PROSTITUTION**).

Why some societies should approve of polyandry and others not has not been satisfactorily explained. Some polyandrous peoples are said to have more men than women and their polyandry has sometimes been directly attributed to this fact, but the evidence on this point is unconvincing. Tibetan polyandry is alleged to check the increase of population in regions from which emigration is difficult, but since most adult Tibetan women bear children this can hardly be the case. The view that polyandry is designed to prevent the dispersal of family property has greater plausibility for some cases. Personal relations within polyandrous families are often markedly free from jealousy. The polyandry of the Nayar is linked historically not only with their matrilineal ideology but also with their military organization, which prevented the men from living the ordinary life of a husband and father of a family. Polyandry may coexist with monogamy and polygyny (*q.v.*).

POLYBIUS (c. 200–after 118 B.C.), the Greek historian of 3rd- and 2nd-century Rome, was born at Megalopolis in Arcadia; his father Lycortas was a distinguished Achaean statesman. The dates of his birth and death have to be inferred. His reference to measurements along the Via Domitia in Narbonese Gaul (iii, 39, 8) suggests that he was still alive in 118, when this road was constructed; if he died from a fall from his horse at the age of 82, as stated in the pseudo-Lucian's *Macrobii*, he was probably born about 200 B.C. This would fit Plutarch's description of him (in his *Philopoemen*) as a boy when he carried Philopoemen's ashes to burial in 182, and also the fact that when appointed ambassador to Egypt in 180 he was under the legal age, which was probably 30 (xxiv, 6, 5; xxix, 24, 6).

Polybius received the upbringing appropriate for a son of rich landowners. His youthful biography of Philopoemen reflected his admiration for the great Achaean leader; and an interest in military matters found expression in his lost book on *Tactics* (ix, 20, 4). He enjoyed riding and hunting, but his knowledge of literature was rather specialized (apart from the historians) and his acquaintance with philosophy superficial. Between 180, when the Egyptian embassy was canceled because of Ptolemy V's sudden death, and 170/169, when he was hipparch in the Achaean confederation, nothing is known of his career. But he then became involved in critical events. Encumbered by their war with Perseus of Macedonia, the Romans were watching for disloyalty in the Greek states. Although Polybius declared for open support of Rome and was sent with the cavalry to the consul Q. Marcius, Achaean help was rejected (xxviii, 12–13). After Perseus' defeat at Pydna (168 B.C.) Polybius was one of 1,000 eminent Achaeans who were deported to Rome at the instigation of the pro-Roman Callicrates, and detained in Italy without trial.

At Rome Polybius had the good fortune to attract the friendship of L. Aemilius Paulus' two sons Q. Fabius Maximus Aemilianus and P. Cornelius Scipio Aemilianus; he became the latter's mentor and through his family's influence was allowed to remain in Rome when the other detainees were distributed into custody throughout Italy (xxxi, 23, 5). It is probable that Polybius accompanied Scipio to Spain in 151, went with him to Africa (where he saw the Numidian king Masinissa) and crossed the Alps in Hannibal's footsteps on his way back to Italy (iii, 48, 12). In 150, through Scipio's influence and Cato's acquiescence, the 300 surviving internees were allowed to return home (xxxv, 6). Shortly afterward Polybius joined Scipio at Carthage and was present at its siege and destruction in 146; and it is likely that he then undertook a voyage of exploration in the Atlantic as related in Pliny's *Naturalis historia*. Meanwhile hostilities had broken out between Achaia and Rome, and Polybius was in Corinth shortly after its destruction (146). He devoted himself to securing as favourable a settle-

POLYBIUS, RELIEF FOUND AT CLITOR IN 1880

ment as possible for his countrymen, and to re-establishing order (xxxix, 5); and as the geographer Pausanias states, Achaean gratitude found expression in the erection of statues in his honour at Tegea; Pallantium, Mantinea, Lycosura—where the inscription declared that "Greece would never have come to grief, had she obeyed Polybius in all things, and having come to grief, she found succour through him alone"—and Megalopolis, where it was recorded that "he had roamed over all the earth and sea, had been the ally of the Romans, and had quenched their wrath against Greece." The inscribed base of a statue erected to him by Elis was discovered at Olympia in 1877; and in 1880 a relief showing Polybius himself in idealized form was found at Clitor (reproduced in F. W. Walbank, *Commentary*, frontispiece; see *bibliography*) and above it a couplet recording that the city raised this most beautiful statue to Polybius, son of Lycortas, in recognition

of his noble deeds. Of Polybius' life after 146 little is known. At some date he visited Alexandria and Sardis (xxi, 38, 7). He is known to have discussed political problems with Scipio and Panætius of Rhodes. He wrote a history of the Numantine War, evidently after 133 B.C., and also a treatise on the habitability of the equatorial region; but when he composed the latter is unknown.

Scope of the History.—The history on which his reputation rests consisted of 40 books, the last being indices. Books i–v are extant. For the rest there are excerpts in the collection of passages from Greek historians assembled for Constantine Porphyrogenitus in the 10th century, rediscovered and published by various editors from the 16th to the 19th centuries; excerpts from books i–xvi and xviii, first published at Basel in 1549; and citations and extracts in numerous authors writing between the 1st and 6th centuries A.D., and from the Suda lexicon and that of Stephanus of Byzantium.

Polybius' original purpose was to narrate the history of the 53 years (220–168 B.C.)—from Hannibal's Spanish campaign to the battle of Pydna—during which Rome had made itself master of the world. Books i–ii form an introduction covering Roman history from the crossing into Sicily against the Carthaginians in 264 and including events in various other parts of the world (especially Achaia) between 264 and 220. In book iii, 4, Polybius sketches a modified plan, proposing to add an account of how the Romans exercised their supremacy down to the destruction of Carthage in 146.

These events of 168–146 were related in books xxx–xxxix. Probably Polybius conceived his revision after 146, having by this date completed his narrative down to the end of the Second Punic War. At least books i–vi seem to have been published by about 150; there is no information as to when the rest of the work, including the revised plan in book iii, appeared.

Conception of History.—"All historians," according to Polybius (i, 1, 2), "have insisted that the soundest education and training for political activity is the study of history, and that the surest and indeed the only way to learn how to bear bravely the vicissitudes of fortune is to recall the disasters of others." Practical experience and fortitude in facing calamity are the rewards of studying history, and are stressed repeatedly throughout the work. History is essentially didactic. Pleasure is not to be wholly excluded; but the scale comes down sharply on the side of profit. To be really profitable history must deal with political and mili-

tary matters; and this is *pragmatike historia*, in contrast to other sorts of history (ix, 1-2)—genealogies and mythical stories, appealing to the casual reader, and accounts of colonies, foundations of cities and ties of kindred, which attract the man with antiquarian interests. Its nature is austere, though it may include contemporary developments in art and science, for instance the fire-signaling perfected by Polybius himself (x, 47). It stands in contrast to the sensationalism of many of his predecessors, who confuse history with tragedy. His remarks on Phylarchus are characteristic (ii, 56, 7 ff.): "In his anxiety to excite his readers' pity and secure their sympathy for what he is describing, he introduces women clinging to altars, their hair dishevelled and their breasts uncovered, and crowds of both sexes together with children and aged parents weeping and lamenting as they are led away to slavery. . . . A historian should not try to astonish his readers by such sensationalism, nor, like the tragic poets, seek after men's probable utterances and enumerate all the possible consequences of the events under consideration, but simply record what really happened and was said, however commonplace. For the object of history is the very opposite of that of tragedy. The tragic writer seeks by the most plausible language to thrill and charm the audience temporarily, the historian by real facts and real speeches to instruct and convince serious students for all time. There it is the probable that counts, even though it be false, the object being to beguile the spectator; here it is the truth, the object being to benefit the student."

This attack on Phylarchus is not isolated. Similar faults are castigated in other historians guilty of sensationalism (cf. ii, 16, 13-15; iii, 48, 8; vii, 7, 1-2; xv, 34, 1-36). Nor are these their only weaknesses. Many historians are prone to exaggeration—and that for a special reason. As writers of monographs whose subjects are simple and monotonous, they are driven "to magnify small matters, to touch up and elaborate brief statements and to transform incidents of no importance into momentous events and actions" (xxix, 12, 3). In contrast Polybius stresses the universal character of his own theme, which is to narrate "how and thanks to what kind of constitution the Romans in under 53 years have subjected nearly the whole inhabited world to their sole government—a thing unique in history" (i, 1, 5). Apart from a general preference for a comprehensive view of history, Polybius had a particular reason for adopting it at that point. "Hitherto the affairs of the world had been as it were dispersed . . . ; since this date (220 B.C.) history has formed an organic whole, and the affairs of Italy and Africa have been interlinked with those of Greece and Asia, all tending towards one end" (i, 3, 3-4). Indeed, only universal history is capable of adequately treating Rome's rise to world power—the historian's synoptic view matches the organic character of history itself: "What gives my work its peculiar quality, and is nowadays most remarkable, is this. Tyche (Fortune) having guided almost all the world's affairs in one direction and having inclined them to one and the same goal, so the historian must bring under one conspectus for his readers the operations by which she has accomplished her general purpose. For it was chiefly this consideration, coupled with the fact that none of my contemporaries has attempted a general history, which incited and encouraged me to undertake my task" (i, 4, 1-2).

The role here allotted to Tyche is somewhat unusual. For clearly the value of history as a source of practical lessons is diminished if cause and effect are at the mercy of an incalculable and capricious power. Usually, although Polybius uses Tyche to cover a variety of phenomena ranging from pure chance to something very like a purposeful providence, much of the apparent inconsistency springs from his use of purely verbal elaboration or the careless adoption of current Hellenistic terminology, which he habitually made Tyche a goddess. Here, however, Tyche seems to be a real directive power, which raised Rome to world dominion—because Rome deserved it. Normally Polybius lays great emphasis on causality, and his distinction (iii, 6) between the causes of an event (*aitiai*) and its immediate origins (*archai*) is useful up to a point, though it is more mechanical than that of Thucydides, and allows nothing for the dialectical character of real historical situations. An important place in Polybius' work is occupied by

his study of the Roman constitution and army and the early history of the city in book vi. His analysis of the mixed constitution, which had enabled Rome to avoid the cycle of change and deterioration to which simple constitutional forms were liable, is full of problems, but it has exercised widespread influence from Cicero's *De republica* down to Machiavelli and Montesquieu.

Sources of Information.—Polybius defines the historian's task as the study and collation of documents, acquaintance with relevant geographical features and, finally, political experience (xii, 25e); of these the last two are the most essential. Polybius practised what he preached; he possessed good political and military experience and he traveled widely throughout the Mediterranean and beyond; as he explains, "I sustained the perils of journeys through Africa, Spain and Gaul and of voyages on the sea adjoining these lands on the outside, in order to correct the errors of my predecessors and make known those parts of the world also to the Greeks" (iii, 59, 7). He did not neglect written sources, however; indeed for his introductory books (i-ii), covering the period from 264 to 220, they were essential. His discussion of Aratus and Phylarchus, his sources for Greece, and of Fabius Pictor and Philinus, those for the First Punic War (i, 14-15; ii, 56, 2; iii, 26, 3-4), indicates his critical approach. For the main part of his history, from 220 onward, he consulted many writers, Greek and Roman; but following precedent he rarely names them. An exception is Zeno of Rhodes, whom he criticizes harshly (xvi, 14-19).

He had access to private sources, for instance Scipio Africanus' letter to Philip V of Macedonia, describing the capture in Spain in 209 B.C. of New Carthage (x, 9, 3) and that of Scipio Nasica to some Hellenistic king about the campaigns of the Third Macedonian War (xxix, 14, 3). He almost certainly consulted the Achaean record office (cf. xxii, 9, 10) and must have drawn on Roman records for such material as the treaty between Carthage and Philip V (vii, 9). That he had access to the Rhodian records has not been proved. His detailed figures for Hannibal's troop formations in Italy came from an inscription left by Hannibal, which he found in the temple of Juno on the Lacinian promontory (iii, 33, 18).

Polybius himself regarded oral sources as his most important, and questioning witnesses as the most vital part of a historian's task (xii, 4c, 2-5); indeed this is one reason why he chose to begin his main history at 220. Anything else would be "hearsay at one remove," a safe foundation for neither judgments nor statements (iv, 2, 3). Of the thousands whom he must have questioned few names can be isolated; but at Rome he had opportunities of meeting men from all parts, including interneers, ambassadors and visitors.

His purpose was to ascertain the truth. "Truth is to history," he writes (i, 14, 6), "what eyesight is to the living creature"; and in the main Polybius achieves this standard. There are exceptions. His prejudice against Aetolia is easily detected and disallowed; and there is some rancour against Boeotia (xx, 5-7). But no serious charges can be leveled against his reliability; and he has stated his own position very frankly: "That historians should show partiality for their own country I would allow, but not that they should make statements about it that contradict the facts. There are enough errors of ignorance to which historians are liable and which a man may hardly avoid. But if we write falsely from intention—be it for country or for friends or for favour—what better are we than those who make their living by such means? . . . Readers should keep a watchful eye on this tendency, and historians themselves should be on their guard against it" (xvi, 14, 6-10).

Style and Qualities as a Historian.—Writing in the 1st century B.C. as a strict Atticist, Dionysius of Halicarnassus reckons Polybius among those who "have left behind them compositions which no one endures to read to the end"; that his successors shared this view of Polybius' style is confirmed by the failure of his works to survive except in an incomplete form. The infelicity of Polybius' Greek (which frequently reproduces the conventional phrases of the Hellenistic chancelleries familiar from contemporary inscriptions) lies in its awkward use of long and cumbersome circumlocutions, vague abstract nouns and pedantic repetitions.

To the scholar his style is, however, no great obstacle; and though in his anxiety to improve his reader he moralizes and labours the obvious, the perennial interest and importance of his theme will always insure him a following among those who can enjoy a historian who is accurate, serious and sensible, understands the events of which he writes, and above all who asks the right questions.

POLYCARP, SAINT (A.D. 70/82-156/168), bishop of Smyrna in Asia Minor, who died a martyr at the age of 86, and whose importance is adequately expressed by the words of the crowd, which are preserved in the moving account of his martyrdom (*Martyrdom of Polycarp*, xii, 2): "This is the teacher of Asia, the father of the Christians, and the destroyer of our gods." Establishing the precise year of Polycarp's death is difficult and represents a famous and inveterate topic of scholarly discussion. The date suggested by the *Martyrdom of Polycarp* is 156, the year given by Eusebius 167/168 (the seventh year of Marcus Aurelius). St. Polycarp's day is Jan. 26.

Better and more reliable information is available about Polycarp than about any other person in the history of the Christian Church in the same period. The earliest mention comes from Ignatius, bishop of Antioch (c. A.D. 110), who on his way to Rome had visited Smyrna, and upon reaching Troas dispatched two letters to Smyrna, one of them to Polycarp personally. There is also extant an Epistle of Polycarp, actually a composition of two epistles, one of them written shortly after Ignatius' departure. Although extant Greek manuscripts give only the text of the first nine chapters of Polycarp's Epistle, missing parts can be supplied from Eusebius, who quotes from it verbatim in his *Ecclesiastical History* (iii, 36, 13-15), and from a Latin translation. Furthermore, the account of Polycarp's martyrdom, written not long after his death, is the oldest and most valuable martyrological account surviving from the ancient church (even if, in its present form, it has been subject to revisions and interpolations in later centuries). Both the Epistle of Polycarp and the *Martyrdom* are customarily counted among the writings of the Apostolic Fathers (q.v.).

In addition to these sources information is supplied by Irenaeus, who as a boy had seen Polycarp and speaks of him several times; and by Eusebius of Caesarea, who preserved parts not only of Polycarp's Epistle but also of the *Martyrdom* in a text more reliable than present manuscripts and who provides additional information concerning the date of his death.

Smyrna (modern Izmir, Turk.) was in Roman times an important trading centre in the province of Asia, in population second only to Ephesus. As bishop of this city, Polycarp was in a very influential position. Since he held the post for more than half a century, and since he possessed extraordinary qualities, Polycarp became the most commanding church leader in the province of Asia and beyond throughout the first half of the 2nd century. This is already evident in the letters of Ignatius, who commends his younger colleague as a pillar of true Christian belief and as an exemplary churchman and bishop with respect to virtue, commitment, and true faith. Ignatius also entrusts Polycarp with the task of sending a messenger to the church in Antioch in order to forward copies of his letters, and of writing himself to other churches which Ignatius was unable to visit.

Shortly afterward, still without any confirmation of Ignatius' death as a martyr in Rome, Polycarp answered a request from the church in Philippi for copies of Ignatius' Epistles, which Polycarp had collected. This collection is the direct basis for the only Greek manuscript that preserves the original text of six of the Ignatian Epistles. The Epistle of Ignatius to the Romans, which could not

have been available to Polycarp at that time, is missing from this manuscript. The covering note which Polycarp sent along to Philippi with the epistles is preserved as a part of the extant Epistle of Polycarp (ch. xiii).

Epistle to the Philippians.—The larger part of this epistle (ch. i-xii and probably xiv) is (as P. N. Harrison has shown) a letter which Polycarp sent to the Philippians a few years or even decades later. The letter shows that Polycarp meanwhile had visited Philippi himself. One of the reasons for his writing is that he wants to give instructions concerning the case of the presbyter Valens, who, with his wife, apparently had embezzled funds (xi, 1-4). Accordingly, exhortations concerning avarice, together with admonitions to lead a virtuous life and special instructions for church officers, make up most of the content. At the same time, however, this epistle, in which Polycarp presents himself as a man of receptive rather than creative qualities of mind, is an important source for the development of tradition, doctrine, and organization of the church at this time. In the preservation and continuation of such traditions and institutions, Polycarp must have had a considerable part; thus, for later generations, he has become an important link between the apostolic age and the early Catholic Church with respect to apostolic tradition and succession.

Although Ignatius writes to Polycarp as "the bishop of the church of the Smyrnaeans," Polycarp, in the Epistle to the Philippians, seems to present himself only as one of the presbyters of that church. In Philippi also he presupposes a college of presbyters (or bishops) and deacons, rather than a monarchical episcopate as it was propagated by Ignatius. Therefore, it would seem, the constitution of the churches in Asia had not yet developed a monarchical structure, though it allowed already for the leadership of such men as Polycarp.

But even if the constitution of Polycarp's church was more primitive than that of Ignatius, his use and evaluation of the authorities of the Christian tradition is further developed than it is in Ignatius' writings or in I Clement (dating from near the end of the 1st century). In the former are sayings of Jesus drawn from the Gospels of Matthew and Luke, whereas Ignatius and I Clement still depend upon oral tradition. Polycarp also includes the oldest quotations from such books of the New Testament as Acts, I Peter and I John, along with the first quotations from such postapostolic writings as I Clement and the first references to the Epistles of Ignatius.

Of primary importance, however, is the way in which Polycarp refers to the apostle Paul. Not only does he repeatedly quote from the Pauline writings, but also he stresses the importance of the apostle's person (cf., e.g., iii, 2; ix, 1). It must be remembered that in the time of Polycarp the great apostle to the gentiles had become a primary authority for the Gnostic heretics. Polycarp, following in the footsteps of Ignatius, reclaims Paul as a treasured possession of the church. Paul is referred to side by side with the other apostles and is obviously included in their number when they are compared with the prophets of the Old Testament and Christ himself as the church's primary authorities (vi, 3). It is apparently to some extent to Polycarp's credit that this disputed apostle has become a theologically respectable part of the tradition entrusted to the church.

Polycarp's obvious dependence upon written sources raises some doubts with respect to Irenaeus' statement (quoted by Eusebius) that Polycarp had personally known John and others of the original apostles of Jesus; Irenaeus may have wanted a link with the apostolic age, although he actually lived one and a half centuries later. Even if he was born in A.D. 70, it is unlikely that Polycarp could have known any of the first-generation apostles. But Irenaeus may be right in saying (in *Adversus Haereses*) that it was Polycarp's influence which prevented the heretic Marcion from settling in the province of Asia. At any rate, Polycarp's Epistle (vii, 1) contains a classical formulation of a doctrine or creed, opposing the Gnostics' denial of the reality of incarnation and crucifixion, their perversion of the sayings of the Lord, and their rejection of resurrection and judgment, a statement that Irenaeus understood to be coined against Marcion as the "first-born of the devil." Noteworthy in this context is H. von

Campanhausen's attempt to interpret the Pastoral Epistles as an anti-Marcionite work of Polycarp. It seems to be clear at least that these deutero-Pauline Epistles from Asia Minor must have been written under the influence of Polycarp. With him they share the theological concern for the apostle Paul as the model church leader, the anti-Gnostic thrust, the concept of the constitution and tradition of the church, and even such details as specific lists of virtues and peculiarities of literary style.

The last information about Polycarp's life that comes to us through Irenaeus pictures very persuasively his qualities of leadership and the high estimation in which he was held outside his own diocese. For years a controversy about the date of the Easter festival had vexed the church and threatened to result in a schism between Asia and Rome. Polycarp, already at the advanced age of 80, undertook a journey to Rome to settle this problem with the Roman bishop Anicetus. Although they could not reach an agreement, they did not break off communion with each other, and as a mark of special honour Anicetus (according to Irenaeus) allowed Polycarp to celebrate the Eucharist in his church.

POLYCLITUS (POLYCLEITUS), the name of two Greek sculptors of the school of Argos; the first belonging to the 5th century B.C., the second to the earlier part of the 4th.

The elder, better-known Polyclitus (fl. 5th century B.C.) was a contemporary of Phidias and in the opinion of the Greeks his equal. Whether he was a pupil of Ageladas is disputed; at least he carried on the Argive tradition. He made a figure of an Amazon for Ephesus which was regarded by later Greek writers as superior to the Amazon of Phidias made at the same time. His colossal Hera of gold and ivory which stood in the temple near Argos was considered as worthy to rank with the Zeus of Phidias. Balance, rhythm, and the minute perfection of bodily form, which were the great merits of this sculptor, appealed especially to the Greeks of the 5th century. Polyclitus worked mainly in bronze.

In regard to his chronology there are data in a papyrus published by B. P. Grenfell and A. S. Hunt containing lists of athletic victors. From this it appears that he made a statue of Cyniscus, a victorious athlete (464 or 460 B.C.), of Pythocles (452), and of Aristion (452). He thus can scarcely have been born as late as 480 B.C. His statue of Hera is dated by Pliny to 420 B.C. His artistic activity must therefore have been long and prolific. His two great statues, ideal or heroic types rather than portraits, are the Diadumenus ("Man Tying on a Fillet") and the Doryphorus ("Spearbearer"), copies of both of which survive. The Doryphorus was known as "The Canon," because it embodied the correct proportions of ideal male form. The most complete copy is from Herculaneum. There are Roman copies in marble of the Diadumenus in London and New York, giving a good basic impression but only a general idea of the finish of Polyclitus' work in bronze. At Delos, French excavators discovered a Diadumenus of more pleasing type and greater finish, a Hellenistic transformation of the Polyclitan type into a youthful Apollo. Among the bases of statues found at Olympia were three signed by Polyclitus, still bearing on their surface the marks of attachment of the feet of the statues. This gives us their pose, and critics such as A. Furtwängler identified several extant statues as copies of figures of boy

athletes victorious at Olympia set up by Polyclitus. Among these the Westmacott athlete in the British Museum is probably a copy of the "Cyniscus."

The Amazon of Polyclitus survives in many copies, among the best being the Lansdowne statue in the Metropolitan Museum of Art, New York. The masterpiece of Polyclitus, his Hera in gold and ivory, has disappeared, but coins of Argos give us the general type. A marble head in the British Museum gives a Greco-Roman version of this type, treated in general terms.

The want of variety in the works of Polyclitus was brought as a reproach against him by certain ancient critics. Varro says that his statues were square and almost of one pattern. Excepting the statue of Hera, the work of his later years, he produced scarcely any notable statue of a deity. His field was narrowly limited; but in that field he was unsurpassed.

The younger Polyclitus (fl. 4th century B.C.) was of the same family as the elder. Sculptures by him have been difficult to

identify among existing copies. Some bases bearing the name, however, are inscribed in characters of the 4th century, when the elder sculptor cannot have been alive. He was also an architect of note. His best-known buildings are the tholos (in ruins) and the theatre (now restored) of Epidaurus (360-330 B.C.).

POLYCRATES, tyrant of Samos, in the Aegean Sea, c. 535-522 B.C., took advantage of a festival of Hera which was being celebrated outside the walls to make himself master of the city. After getting rid of his brothers Pantagnotus and Syloson, who had at first shared his power, he established a despotism, equipped a fleet of 100 ships and so became master of the Aegean basin. His numerous acts of piracy made him notorious throughout Greece; but his real aim was the control of the archipelago and the mainland towns of Ionia. He maintained an alliance with Lygdamis of Naxos and dedicated to Apollo of Delos the neighbouring island of Rheneia (Rinia). He also defeated a coalition of Miletus and Lesbos. He made an alliance with Ahmose (Amasis) II, king of Egypt, but when the Persians advanced against Egypt in 525 he abandoned his ally and sent a squadron of 40 ships to join the Persian fleet. He took the opportunity to send his main political opponents with this squadron, but they deserted the Persians and attempted to dislodge Polycrates. After a defeat by sea, he repelled an assault upon the walls, and subsequently withstood a siege by a joint force of Spartans and Corinthians assembled to aid the rebels. He maintained his ascendancy until about 522, when Oroetes, the Persian governor of Sardis, lured him to the mainland and put him to death.

Besides the political and commercial preeminence which he conferred upon Samos, Polycrates built an aqueduct and a harbour mole. He was also a patron of letters; the poet Anacreon lived at his court. (R. ME.)

POLYCYTHEMIA VERA: see BLOOD, DISORDERS OF: *Polycythemia*.

POLYDORUS, the name of two figures in Greek mythology.

1. Polydorus, youngest son of Priam and Laothoe (Homer, *Iliad* xxii, 46) or Hecuba (Euripides and later writers). In Homer,

Polydorus is killed in battle by Achilles. Euripides (*Hecuba*) tells how Priam sent Polydorus with great treasures to Polymestor, king of Thrace, who murdered the boy for the money and threw his body into the sea; the corpse was tragically discovered later by Hecuba. Virgil (*Aeneid* iii, 22 ff.) has Polymestor bury Polydorus, polluting Thracian soil against Aeneas' settlement.

2. Polydorus was the son of Cadmus, father of Labdacus and ancestor of Oedipus. (Wm. S. A.)

POLYETHYLENE, any of a group of light-weight plastics that can be made soft to hard, flexible to rigid, translucent or coloured, the most popular being white and leathery. They are resistant to most chemicals, impermeable to water, and good electrical insulators. Since the early 1960s more polyethylene has been manufactured than any other plastic, mostly as films and sheets, for packaging everything from foods to hardware, and as bags (including balloons for high-altitude flight). The rest is made into squeeze bottles and other containers, piping, and insulation. Polyethylene is produced by polymerization of ethylene (*q.v.*), using various catalysts, including alkyl metal derivatives with titanium tetrachloride, temperatures up to 300° C and pressures greater than 1,000 atm. The reaction is represented as $n\text{CH}_2=\text{CH}_2 \rightarrow (-\text{CH}_2-\text{CH}_2-)_n$ where n is the number of molecules, which may exceed 100,000, giving a molecular weight as high as 3,000,000. The polyethylene is obtained in the form of flakes, sheets, molding and extruding compounds, and these, with additives, are turned into the finished products. Polyethylene with molecular weight less than 6,000 is a liquid. Polyethylenes first gained commercial importance in England in the 1930s.

POLYGALACEAE, the milkwort family of dicotyledonous herbs, shrubs, and small trees, comprising about 10 genera and about 700 species, not represented in New Zealand, Polynesia, and the Arctic zone, but otherwise cosmopolitan. In North America about 50 species are native, chiefly in the southern and western United States. *Polygala vulgaris* is the common milkwort (*q.v.*), native to Britain, and *P. senega*, the seneca snakeroot (*q.v.*), is a North American plant.

POLYGLOT BIBLES are Bibles that contain side-by-side versions of the same text in several languages (Gr. *polys*, "many," *glotta*, "tongue"). The most important polyglots are editions in which the Hebrew and Greek originals are exhibited along with the great historical versions. The famous *Hexapla* of Origen (*q.v.*), in which the Old Testament Scriptures were written in parallel columns, probably suggested the later polyglots, but though it gives six texts it is itself in only two languages.

In the 16th and 17th centuries polyglots became a favourite means of advancing the knowledge of Eastern languages as well as the study of Scripture. The most celebrated of these is the Complutensian Polyglot (1522), produced under the inspiration of Cardinal Francisco Jiménez de Cisneros and published in six volumes at Alcalá (Roman *Complutum*) in Spain; it had the Old Testament in Hebrew, Greek, and Latin, the New in Greek and Latin. The Antwerp Polyglot (eight volumes, 1569–72), published by Christophe Plantin (*q.v.*) and edited by Benito Arias Montano, added the Syriac New Testament, with a Latin translation. The Paris Polyglot (ten volumes, 1629–45) added the Arabic, with Latin translation, and the so-called Samaritan Pentateuch, a Hebrew version that differs slightly from the standard Masoretic text and that had first become known in Europe only a few years earlier. The London Polyglot (six volumes, 1657), edited by Brian Walton, added other versions as well as several Targums and readings from the Codex Alexandrinus, which had reached England in 1627.

POLYGNOTUS (c. 500–440 B.C.), Greek painter, son of Aglaophon, was a native of Thasos who soon moved to the Greek mainland and eventually acquired Athenian citizenship. His fame was based on large, monumental wall paintings in the severe style, admired by posterity but now totally lost. The following titles are mentioned by ancient writers: (1) Plataeae, entrance porch of the temple of Athena Areia: "Ulysses after the punishment of the suitors"; (2) Athens, Painted Hall ("Poikile"): "The taking of Ilium"; (3) Athens, Temple of the Dioscuri ("Anakeion"): "Wedding of the daughters of Leucippus"; (4) Athens, Acropolis

("Pinacotheca"): "Achilles in Scyros"; (5) Same as no. 4: "Nausicaa"; (6) Delphi, Hall ("Lesche") of the Cnidians: "Departure of the Greeks from Ilium"; and (7) Same as no. 6: "Ulysses visiting Hades."

Pausanias left an account of the last two paintings (Paus. x, 25–31) from which, with occasional support of other sources, the following characteristics of Polygnotus' style are deduced. Figures approximating life-size were freely distributed within the composition, near the lower border and higher. In Greek painting of the first half of the 5th century B.C. this method represents an innovation, though precedents existed elsewhere, notably in Assyrian art. It constitutes a break with the ancient Greek principle of arranging figures on a single base line; Polygnotus replaced the horizontal base lines by irregular, mounting or descending terrain lines. Comparable representations can be found in contemporary vase paintings, perhaps under his influence. There was no unifying perspective in the modern sense: the individual figure remained the focus of interest even when several figures were grouped together. Stateliness was paired with subtlety of detail: delicate headdresses of women, transparent garments, mouths with parted lips uncovering the teeth. Sharp foreshortenings were not lacking. Coloration consisted of four basic colours: black, white, red and ochre. None of the last named characteristics can be claimed for Polygnotus alone: he was merely the outstanding representative of the severe style in Greek monumental painting. The "ethos" which later critics, including Aristotle (*Poetics*, ch. 6), valued so highly in his work indicates a concept of character as an innate disposition, governing the actions and manifest in a person's outward bearing.

See Carl Weickert, "Studien zur Kunstgeschichte des 5. Jahrhunderts v. Chr. I, Polygnot," *Abhandlungen der Deutsch. Akademie der Wissenschaften*, vol. 1947, no. 8 (1950). (O. J. Bl.)

POLYGON, in classical geometry, a simply connected plane region bounded by straight line (*q.v.*) segments (its sides) which meet in corners of the region (its vertices). In modern mathematics the word usually denotes only the boundary (sides and vertices); the region is called a polygonal region. A region is called simply connected if any two points within it can be joined by a continuous path lying wholly within it, and if any such path can be continuously deformed into any other that joins the same two points, remaining within the region throughout (see *TOPOLOGY, GENERAL*).

If there are n vertices the polygon is called an n -gon; when $n = 3, 4, 5, 6, \dots$ it is called a triangle, a quadrangle, a pentagon, a hexagon, . . . , accordingly. The vertices can be written in order, say $A_1 A_2 \dots A_n$, so that the n sides are $A_i A_{i+1}$ (for $i = 1, \dots, n-1$) and $A_n A_1$. If a sense or orientation is attached to any segment XY by regarding it as described from X to Y (so that YX denotes the same segment with the opposite orientation), this specification of the sides, the end of each being the beginning of the next, gives a continuous description of the polygon. This is then said to be oriented, the orientation being positive or negative according to the position of the region to left or to right of the boundary as it is described; i.e., according to whether travel around it is counterclockwise or clockwise. The orientation does not depend on the vertex (in this case A_1) chosen to begin and end the description. If no sense is attached to the sides the polygon is unoriented. Thus ABC, BCA, CAB denote the same oriented triangle, with sides BC, CA, AB , while ACB, CBA, BAC denote the same triangle oppositely oriented, and all denote the same unoriented triangle.

More generally, if A_1, \dots, A_n are any n points, the closed path consisting of the segments $A_i A_{i+1}$ ($i = 1, \dots, n-1$) and $A_n A_1$ is called a polygon (oriented if the segments are so) even if it crosses itself or is not in one plane. In the latter case it is called a skew polygon as opposed to a plane-polygon. It is called simple if it is in fact the boundary of a plane region, and convex if the region is so (which means that the line segment joining any two points of the region lies wholly within it). If one side be omitted, say $A_n A_1$, the others form a continuous path (oriented or not) joining A_1 to A_n , which is called a polygonal line.

Angles of a Plane Polygon.—Generalizing the familiar idea

of an internal angle of a polygonal region and its supplement, the external angle, the following definitions are made for any oriented plane polygon (the first two definitions agreeing with the elementary notions if the polygon is simple and positively oriented):

FIG. 1.—POLYGONAL ANGLES

if AB, BC are any two consecutive sides (fig. 1), the internal angle α at B is the least positive angle from the direction BC to the direction BA ; the external angle β is the absolutely least angle (positive or negative) from the direction AB to the direction BC ; and the peripheral angle γ is the least positive angle from the direction AB to the direction BC . These (measured in radians) satisfy $\alpha + \beta = \pi$ in all cases, and $\gamma = \beta$ or $\gamma = \beta + 2\pi$ according as α is less or greater than π (see RADIANT MEASURE). If α', β', γ' are the corresponding angles when the orientation is reversed, then $\alpha' = 2\pi - \alpha, \beta' = -\beta, \gamma' = 2\pi - \gamma$. The algebraic sums of these angles over all the vertices of an n -gon are $\Sigma\alpha = (n - 2p)\pi, \Sigma\beta = 2p\pi, \Sigma\gamma = 2q\pi$, where p, q are integers; p can have any value absolutely less than $\frac{n}{2}$ (positive, negative, or zero) and q any value from 1 to $n - 1$. If the polygon is simple, $p = \pm 1$; and a necessary and sufficient condition for it to be convex and positively oriented is that $p = q = 1$.

Classification of Plane Polygons.—If no two nonconsecutive sides of a plane polygon intersect it is "simple," and if in addition the external angles all have the same sign it is "convex." The specification of the intersections (if any) of nonconsecutive sides and of the changes of sign of the external angle in going around the polygon defines for each n a finite number of types of plane n -gon such that two polygons are of the same type if and only if one can be continuously deformed into the other, remaining in the plane, without any vertex crossing over a side and without two consecutive sides becoming collinear during the process. Omitting intermediate cases in which some side contains a vertex other than its end points, there are 1, 3, 11, 70, . . . types of un-oriented triangle, quadrangle, pentagon, hexagon, . . . respectively, most of which correspond to two oriented types. These types are

FIG. 2.—TYPES OF QUADRANGLE

partly characterized by the numbers p, q above; thus the three types in fig. 2 (the first two positively oriented) have respectively $p = q = 1; p = 1, q = 2; p = 0, q = 2$. On the other hand these numbers do not provide a complete basis for the classification, as in fig. 3. They have the same values for types 3 and 4, 6 and 7, and 8, 10, and 11.

The Encircling Coefficient.—If O is any point in the plane of an oriented polygon (but not in any of its sides) the angle subtended at O by a side AB is defined as the absolutely least angle (positive or negative) from the direction OA to the direction OB . The algebraic sum of the angles subtended at O by all the sides of an oriented n -gon is of the form $2k\pi$, where k is an integer (positive or negative) absolutely less than $\frac{n}{2}$, which is called the encircling coefficient of the polygon at O . In a sense k is the number of times that O is encircled counterclockwise in describing the polygon.

The sides of any plane polygon divide the whole plane into a number of nonoverlapping polygonal regions and one infinite external region. The integer k has the same value at all points of any one such nonoverlapping region, and is zero at any point of the external region. If the polygon is simple, $k = \pm 1$ (according to the orientation) at any point within it.

Area of a Polygon.—It is convenient to regard the area of (the region bounded by) an oriented simple plane polygon as being positive or negative according to the orientation of the polygon. With this convention let O be any point in the plane; each oriented side of the polygon, say AB , determines with O an oriented triangle OAB ; and the algebraic sum of the areas of the n oriented triangles thus determined by all the sides of an oriented n -gon can be shown to be independent of O ; this sum is in fact the area

FIG. 3.—TYPES OF PENTAGON

of the n -gon. If O is chosen at a vertex of the n -gon, two of these triangles vanish, and there is a dissection of the n -gon into $n - 2$ triangles by means of $n - 3$ diagonals; this is the classical method of finding the area.

If the plane n -gon is not simple, it can still be proved that the algebraic sum of the areas of these n oriented triangles is independent of O ; and this is accepted by definition as the area of the polygon. It is in fact the sum of the areas of the polygonal regions into which the sides of the polygon divide the plane, each multiplied by the corresponding encircling coefficient.

If O is the origin of a cartesian coordinate system, and A_i has coordinates (x_i, y_i) ($i = 1, \dots, n$), this leads to the expression $\frac{1}{2}(x_1y_2 - x_2y_1 + x_2y_3 - x_3y_2 + \dots + x_{n-1}y_n - x_ny_{n-1} + x_ny_1 - x_1y_n)$ for the area of the oriented n -gon $A_1 \dots A_n$.

FIG. 4.—REGULAR CONVEX POLYGONS

Polygonal Approximation.—Study of polygons is valuable to mathematics in general largely because polygonal regions and polygonal lines can be used to achieve as close an approximation as desired to most ordinary plane regions and curved lines. People in ancient times, for instance, obtained very good approximate values for π by comparing a circle ($q.v.$) with inscribed and circumscribed regular polygons that have a large number of sides (see LIMIT).

A polygonal approximation to a closed curve is a polygon with vertices that are all on the curve in the same order as in the polygon, so that if AB, BC are consecutive sides of the polygon, then B and no other vertex is in one arc AC of the curve. The shorter the longest side of the polygon, and the greater consequently the number of its vertices, the closer the approximation. An arc of a curve is similarly approximated by a polygonal line joining its end points. A plane region is often approximated by superimposing on the plane a mesh of squares (like ordinary graph paper) and by constructing a polygonal region as the aggregate of all squares of the mesh that are wholly inside the given region. Here, the finer the mesh the closer the approximation.

In wide classes of cases as close an approximate value as may be required can be obtained for the length of a curve or arc, or for the area of a plane region, by considering a sufficiently close polygonal approximation—often indeed an exact value. For instance, for a given curve, if it can be shown, as it often can, (1) that the perimeter (sum of the lengths of the sides) of every polygonal approximation is less than some fixed length s , but (2) that by taking the approximation close enough, in the sense explained above, the perimeter can be made to differ from s by as little as

may be required, then it is justifiable to accept s as the length of the curve. Similar considerations apply to area. The technique of this process, and the determination of the cases to which it is applicable, belong to integral calculus (see CALCULUS, DIFFERENTIAL AND INTEGRAL).

Regular Polygons.—A polygon is called regular if all its sides are equal in length and all its internal angles are equal (when, of course, all its external angles are likewise equal). All the vertices lie on one circle, the circumcircle, and all the sides touch another, the incircle. These have the same centre, called the centre of the polygon. A regular triangle is called equilateral, and a regular quadrangle is a square; fig. 4 shows the next four convex cases.

Besides these convex polygons there are (for values of n greater than 4) nonsimple regular n -gons (called regular star polygons) constructed as follows: if $A_1 \dots A_n$ is a regular convex n -gon, the sides of a new polygon are obtained by joining each vertex A_i , not to the next A_{i+1} , but to the d th following A_{i+d} (or A_{i+d-n} if $i+d$ is greater than n); where d is any integer less than $\frac{n}{2}$, and

FIG. 5.—REGULAR STAR POLYGONS

has no common factor with n except 1. The number d is called the density of the star polygon, and is equal to its encircling coefficient at the centre; $d = 1$ of course gives the convex n -gon. (If d, n have any common factor this construction gives more than one polygon, as in the first example in fig. 5.)

Regular skew polygons are also defined; these always have an even number of vertices, lying alternately on two equal circles in parallel planes, and the projection onto any plane parallel to these is a regular plane polygon.

Symmetry.—A regular plane n -gon is made to coincide with its former position if it is either (1) rotated about its centre through an angle that is any multiple of $\frac{2\pi}{n}$, or (2) reflected in any one of n lines through the centre (axes of symmetry), each joining two points that are either vertices or midpoints of sides (fig. 4); these reflections however reverse the orientation. Both kinds of operation are called the symmetry operations of the polygon. The symmetry operations of a regular skew $2n$ -gon are of four kinds: (1) rotation through angles that are all multiples of $\frac{2\pi}{n}$ about a principal axis perpendicular to the planes of the two circles containing the vertices and joining their centres; (2) rotations through the angle π about each of n axes perpendicular to this, joining the midpoints of opposite sides; (3) reflection in each of n planes, each joining the principal axis to a pair of opposite vertices; and (4) rotation about the principal axis through angles that are all odd multiples of $\frac{\pi}{n}$, combined with reflection in the plane perpendicular to this axis, which contains the midpoints of all the sides. Operations of types (2) and (3) reverse the orientation.

A plane polygon is sometimes called semiregular if it has an even number of vertices and either (1) the internal angles are all equal and the vertices lie on one circle but alternate sides have two different lengths and touch two concentric circles, or (2) all sides are equal and touch one circle but the angles have two different values alternately, and alternate vertices lie on two concentric circles (fig. 6). A semiregular $2n$ -gon has the same sym-

FIG. 6.—SEMIREGULAR HEXAGONS

metry operations as a regular n -gon.

Ruler and Compass Construction.—The construction of regular polygons by (ungraduated) ruler and compass only is a classical problem; its solution for the triangle is Euclid's first proposition; he also solved it for the square and the pentagon. The problem can be proved to be equivalent to that of finding the ratio of two lengths that determine the shape of the figure, such as the side and the radius of the circumcircle, by solving one or more quadratic equations (see GEOMETRY: Greek Geometry).

It is a remarkable result, due to C. F. Gauss, that this can be done for the regular n -gon if and only if the odd prime factors of n are all different, and all of the form $2^{2k} + 1$, where k is an integer. The first five prime numbers of this form are 3, 5, 17, 257 and 65,537; and there is reason to conjecture that there are no others. See also TRIANGLE; SQUARE; QUADRILATERAL; FIGURATE NUMBERS; MENSURATION.

POLYGONACEAE, the buckwheat family of dicotyledonous plants of about 40 genera and 800 species, consisting chiefly of herbs, although shrubs, vines and even trees occur.

Among the important cultivated food plants in the family are buckwheat (*q.v.*; *Fagopyrum esculentum*) and rhubarb (*q.v.*) or pieplant (*Rheum rhabarbarum*). Ornamentals include several old world species of *Polygonum* such as silver lace vine (*P. auberti*), coral vine (*Antigonon*) from Mexico and the sea-grape (*Coccoloba uvifera*), whose fleshy sepals form an edible berrylike structure.

Common weeds that belong to this family are knotweed (*q.v.*) or knotgrass (*Polygonum aviculare*); the vine, black bindweed (*Polygonum convolvulus*); and dock or sorrel (*q.v.*) (several species of *Rumex*). In this last genus, the three inner sepals, known as valves, enlarge and surround the fruit.

To the Polygonaceae belong such wild plants as mountain sorrel (*Oxyria digyna*), smartweed and water pepper (several species of *Polygonum*), canaigre (*Rumex hymenosepalus*; see DOCK), whose root is a source of tanning material and dye, and California buckwheat (*Eriogonum fasciculatum*), an important bee plant in its native range.

The stems are often swollen at the nodes (whence comes the genus name *Polygonum*, referring to the many joints or knees). The leaves are alternate, usually simple and entire, and stipules at the base of the leaves usually form a highly characteristic sheathing growth (ocrea) around the stem. The flowers, often borne in clusters, are radially symmetrical, lacking petals, and usually small. The calyx generally consists of five or six separate or united sepals. These are usually green or white, but other colours such as rose and yellow also occur. The stamens vary in number from five to nine and the achenelike fruit is one-celled, one-seeded and usually three-carpellate and three-sided. The single seed is erect and attached at the base of the fruit. The flowers, usually bisexual, are wind- or insect-pollinated (depending on the genus), or sometimes self-pollinated. The family is so distinct from its nearest relatives that it is placed in a separate order, the Polygonales.

The apparently basic type of flower has six sepals (two whorls of three), nine stamens and three united carpels; such a flower is usual in *Eriogonum*. Although examples with the flower parts in fours occur, the usual variation is a reduction in number of one or all of the parts. Five sepals and five to eight stamens are frequent in *Polygonum*; two whorls of two (2 + 2) sepals and two united carpels characterize *Oxyria*.

The family occurs primarily in the northern hemisphere. As is true in many plant families, the geographic distribution of the genera often provides interesting problems. *Polygonum* (about 200 species) is widely distributed, whereas *Rumex* is strictly Asian, and *Muehlenbeckia* (15 species) is unusual because it is limited almost entirely to the southern hemisphere. *Coccoloba*, with 125 species, is confined to the American tropics and subtropics. Several small genera (e.g., *Gilmania*, *Hollisteria*, *Mucronea*) are limited to California, while the one species of *Koenigia*, in addition

to being circumboreal, is found also in the Himalayas and in Tierra del Fuego. Of the two species of *Brunnichia*, one occurs in the southeastern part of the United States, the other in west Africa.

The tribe *Eriogoneae* is strictly American and occurs almost entirely in the western portion of the United States. It is unusual in lacking the ocreae so characteristic of the family. Besides several small genera, the tribe includes *Chorizanthe* (60 species) and *Eriogonum*, nearly 200 species. (G. J. G.)

POLYGRAPH, popularly known as the lie detector, a device for simultaneously measuring and recording various bodily functions such as heartbeat, blood pressure, and respiration rate. Because these functions tend to fluctuate abnormally when a person attempts to lie or deceive, the polygraph is used extensively in the investigation of crime. Many authorities, however, maintain that its results are questionable, even when tests are conducted by skilled operators (see INVESTIGATION, CRIMINAL: *Detection of Deception*).

POLYGYNY, the system under which a man is married to several women at the same time, a type of polygamy or plural marriage. Polygyny is nowhere the exclusive form of marriage, and among most peoples who permit it the large majority of men live in monogamy. It may be modified in a monogamous direction both from the social and the sexual point of view. Frequently one of the wives, generally the one first married, holds a higher position than the rest or is regarded as the principal wife. In some cases this position implies certain sexual privileges; but more often it is the custom for the husband to cohabit with wives in turn, or this is actually required of him.

Primitive Societies.—Among preliterate peoples polygyny does not seem to be practised on a large scale by the hunters and food collectors, except some Australian and Bushman tribes, nor by any incipient agriculturists. On the other hand, a considerable number of these hunting and slightly agricultural tribes—such as some of the South American Indians, the aboriginal tribes of the Malay peninsula, most of the Andaman Islanders, the Veddas of Ceylon, certain tribes in the Malay archipelago, most of the Negritos of the Philippine Islands and some at least of the central African pygmies—are represented as monogamous. Among more well-to-do hunters polygyny is more frequent, although in the majority of their tribes it is practised only occasionally; and exclusive monogamy is rare, though perhaps not unknown. Among pastoral peoples there seems to be none that can be regarded as strictly monogamous; and both among them and the higher agriculturists polygyny is undoubtedly more frequent than among the hunters and incipient agriculturists, although cases of regular monogamy are more frequent among the higher agriculturists than among the higher hunters. The cases in which polygyny is represented as general are comparatively much more numerous among African than non-African pastoral peoples and higher agriculturists. Polygyny is at its height in Africa, both in point of frequency and in number of wives. King Mutesa of Uganda and the king of Loango each are said to have had 7,000 wives.

Ancient Civilizations.—Polygyny, or a sort of concubinage hardly distinguishable from genuine polygyny, was found among most peoples of archaic civilization. In China there were, besides the legal principal wife, so-called wives "by courtesy" or lawful concubines. In Japan concubinage of the Chinese type existed as a legal institution until 1880. In ancient Egypt polygyny seems to have been permitted but to have been unusual, except in the case of kings. The Babylonian code of Hammurabi assumed that marriage should be monogamous; yet "if a man has married a wife and a sickness has seized her," he might take a second wife; and if she remained childless he might take a concubine. Among the Hebrews a man could in any circumstances have a plurality of wives, and there was no difference in the legal status of different wives, nor was there any limit to the number of wives a man might take. In Arabia Mohammed ordained that a man's legal wives should be not more than four. Polygyny has been permitted among many of the Indo-European peoples—among ancient Slavs and Teutons, the ancient Irish and the Vedic Indians—though it seems to have been as a rule confined to kings or chiefs or nobles. None of the Hindu lawbooks restricts the number of wives a man

is allowed to marry; yet some preference is often shown for monogamy, and most castes object to their members having more than one wife, except for some cogent reason. On the other hand, there can be little doubt that monogamy was the only recognized form of marriage in Greece; concubinage existed in Athens, but it was well distinguished from marriage, conferring no rights on the concubine. Roman marriage was strictly monogamous; liaisons between married men and mistresses were not uncommon, but such a relation was not considered lawful concubinage.

Modern Times.—Polygyny has been found even in Christian Europe. No obstacle was put in the way of its practice by kings in countries where it had occurred in the times of paganism. In the middle of the 6th century Diarmait, king of Ireland, had two queens and two concubines. Polygyny was frequently practised by the Merovingian kings. Charlemagne had two wives and many concubines; and one of his laws seems to imply that polygyny was not unknown even among priests. In later times Philip of Hesse and Frederick William II of Prussia contracted bigamous marriages with the sanction of the Lutheran clergy. In 1650, soon after the peace of Westphalia, when the population had been greatly reduced by the Thirty Years' War, the Frankish *Kreistag* at Nürnberg passed the resolution that thenceforth every man should be allowed to marry two women. The Anabaptists as well as the Mormons once advocated polygyny with much religious fervour.

Causes.—One cause of polygyny can be an excess of marriageable women in certain age groups. But while the existence of available women makes polygyny possible, the direct cause of it is generally the man's desire to have more than one wife. There are various reasons for this desire. Among many of the simpler peoples the husband has to abstain from his wife during her pregnancy, or at least during the latter stage of it, and after childbirth until the child is weaned, which often means an abstinence lasting for a couple of years or more. Other contributing factors are the attraction of youth and beauty, the desire for many children—which is one of the principal causes of polygyny in the east—and the fact that polygyny may contribute to a man's material comfort or wealth, and thereby his social importance. But it should also be noted that the paying of a dowry, the amount of which is influenced by economic conditions, makes it possible for certain men to acquire several wives while others can acquire none at all.

POLYMERIZATION, in chemistry, was originally considered to be any process in which two or more molecules of the same substance unite to give a molecule (polymer) with the same percentage composition as the original substance (monomer), but with a molecular weight which is an integral multiple of the original molecular weight. A special case exists when the monomer and polymer are so easily interconvertible that their isolation and chemical distinction are difficult; this condition is usually considered to be association (see ASSOCIATION, CHEMICAL).

The term "polymerization" now applies when the monomer and polymer are easily distinguished; it applies also to preparations of some polymers which do not conform to the original definition (see below). Polymerization is the process by which plastics, resins and rubber are synthesized.

This article is concerned with the general principles of polymerization processes, particularly with the processes that produce polymers of high molecular weight (high polymers).

Addition Polymerization.—This process occurs when monomer units simply join together to form polymers. The process

usually requires a double or triple bond in the structural formula of the monomer. Although a carbon-oxygen or carbon-nitrogen multiple bond will serve (see FORMALDEHYDE), most examples involve carbon-carbon double bonds, particularly olefins with $>C=CH_2$ groups (see CHEMISTRY: Organic Chemistry for many terms used here). Some polymers contain only two or three monomer units (see TERPENES), some contain many, and some monomers yield more than one kind of polymer. Phosphonitrile chloride, $P \equiv NCl_2$, is an inorganic monomer yielding several addition polymers.

The polymerization of styrene (*q.v.*) illustrates addition polymerization. The monomer is a colourless, mobile liquid. On standing for several weeks at room temperature, for a few days at $100^\circ C$, or for a shorter time at higher temperatures, the liquid polymerizes, becoming first an increasingly viscous solution of polymer in monomer, and finally a clear, odourless, glassy solid. The polymer is a mixture of molecules of the formula $(C_8H_8)_n$, where n has a wide range of values and averages several thousand. When the monomer is warmed with 1% or less of an initiator such as benzoyl peroxide, $C_6H_5-CO-O-O-CO-C_6H_5$, a similar polymer is formed, but in minutes or hours instead of days or weeks. These processes are chain reactions, starting when styrene is activated thermally, or when the initiator decomposes, to give electrically neutral fragments of molecules, with free or unsaturated valences (free radicals with trivalent carbon atoms). Such a fragment, $R-$, adds easily to the double bond in the monomer

forming a larger radical with the free valence now on the styrene unit. This new free radical adds to another double bond, and so on, so that many monomer units become linked together in a linear (threadlike) polymer. Thousands of steps in a single reaction chain may occur in a second, the reaction ending when two radicals interact and mutually destroy their free valences.

Similar polymerizations are industrially important both with liquids (*e.g.*, vinyl acetate, acrylic esters, acrylonitrile) and with gases under pressure (*e.g.*, ethylene, butadiene and vinyl chloride). Such polymers have a wide range of physical properties (see PLASTICS; ETHYLENE; BUTADIENE). To avoid difficulties in handling large masses of hard or viscous polymer, large-scale polymerizations are frequently carried out in emulsion or suspension in water to produce synthetic latex or beads.

Initiators which do not produce free radicals may also be employed. Some metal halides (aluminum chloride or boron trifluoride), sulfuric acid, metal alkyls (from sodium, lithium or aluminum; see ORGANOMETALLIC COMPOUNDS) and strong bases (sodamide) also cause addition polymerization of some olefins, but here the growing chains are usually ion pairs. These initiators require anhydrous conditions since the polymer ions are destroyed by water. Although styrene and butadiene are polymerized by all the initiators mentioned, the choice of initiators for most monomers is limited.

Considerable heat is evolved when high polymers are formed, and the process can become violent. The driving force in the polymerization is the conversion of the double bond in each monomer to two single bonds in the polymer. In a sense, the strain in the double bond is thus relieved. However, in the polymer, the monomer units are crowded together and restricted in their motions. These restrictions become more important at increasing temperatures, and high polymers made from larger monomers begin to revert to monomer above $200^\circ C$. Polymers from smaller monomers hold together better, but at $300^\circ-400^\circ C$ they also break up, yielding complex mixtures and rather little monomer.

When a mixture of two monomers is subjected to polymerization, the product may contain both monomers in each polymer molecule (*i.e.*, copolymerization of two monomers yields a copolymer), or it may contain only one kind of monomer in each polymer molecule, depending on the monomer and type of initiator. Many commercial polymers are actually copolymers, a wider range of properties being possible than with single monomers.

Two polymers may have atoms joined together in the same

sequence, but still have different physical properties because of different spatial relations among the atoms (see STEREOCHEMISTRY; The Stereochemistry of Carbon). Lowering the temperature of polymerization for SBR synthetic rubber from 50° to about $5^\circ C$ has resulted in the improved "cold rubber." Natural rubber has been duplicated by polymerizing isoprene with specific organometallic catalysts. Similar catalysts have produced crystalline modifications of polystyrene and polypropylene which melt above $150^\circ C$, instead of softening below 100° .

Condensation Polymerization.—This is the process of making products, commonly called polymers, with the formation of a small, easily removed molecule (often water) for each step in the process. For making high polymers, the general method is to choose a simple and clean organic reaction, to make it possible for this reaction to take place at each end of every molecule, and to force the reaction to completion by removing the water (or other volatile condensation product) from the reaction mixture. Reactions which give amides or esters are particularly useful. For example, a polyamide can be made either from an amino acid, $H_2N-(CH_2)_x-CO_2H$, or from an equimolecular mixture of a dibasic acid, $HO_2C-(CH_2)_y-CO_2H$, and a diamine, $H_2N-(CH_2)_z-NH_2$. Proteins are polyamides assembled from many amino acids in a very specific manner by enzymes. Starch and cellulose can be considered to be made similarly from glucose units. The condensation of a dihydroxysilane produces a silicone (*q.v.*) polymer. (See also AMIDES; ESTERS; PROTEINS; STARCH; CELLULOSE.)

For polymerization to occur, each molecule must contain two potential open ends and the monomer units must join end-to-end into linear polymers. Such polymers are usually soluble in suitable solvents, soften (reversibly) on heating, and are termed thermoplastic. However, if the monomers contain more than two sites of reaction (*e.g.*, butadiene, glycerol, phenol, tribasic acids), then netlike (cross-linked) instead of threadlike molecules result. When the networks grow large enough, they become equivalent to many linear polymer molecules joined together in a single network. At this stage, the polymers are insoluble and infusible and are termed thermosetting. See PLASTICS: Causes of Resinification, Synthetic Resin Plastics; RESINS: Synthetic Resins; RUBBER: Development of Synthetic Rubber; see also references under "Polymerization" in the Index.

See C. E. H. Bawn, "New Kinds of Macromolecules," *Endeavour*, vol. 15, pp. 137-143 (1956); P. J. Flory, *Principles of Polymer Chemistry* (1953). (Fk. R. M.)

POLYMORPHISM, GENETIC, a type of variation found throughout the animal and plant kingdoms. The concept was defined by E. B. Ford as: "the occurrence together in the same habitat of two or more discontinuous [distinct] forms of a species in such proportions that the rarest of them cannot be maintained merely by recurrent mutation." Polymorphism provides differentiation within a species and thus betters the chances of survival for that species: polymorphic forms, which may be considered genetically controlled varieties, are adapted to conditions different from those to which the rest of the species is adapted. Such variants are maintained at fairly constant levels at frequencies higher than their respective mutation rates in a freely breeding population. Characters that exhibit polymorphism include colour, sexual features, caste in certain insects, clutch size in birds, blood groups, chromosomal variation and disease resistance. (For an explanation of the terms used in this article see GENETICS: Introduction.)

Genetic polymorphism does not include: (1) geographical variation; (2) "continuous" variation controlled by numerous genes acting cumulatively (to illustrate: sex, which is determined by a single pair of genes, does provide an example of polymorphism, whereas variation in human height, dependent on many genes, does not); (3) disadvantageous recessive conditions, for example, albinism in man and many other species, or rare disadvantageous heterozygous conditions. These last-mentioned categories are both eliminated by selection and recur only by mutation.

It has been demonstrated by R. A. Fisher that genes of rel-

atively neutral survival value are rare and that when one of them does arise (by mutation), it can spread only very slowly; indeed its neutrality will always be lost, owing to changing conditions, before it has affected more than a small proportion, say 1% or so, of any considerable population. But any mutant will begin to spread if its effects confer upon an organism an over-all advantage because of a change in the environment or in the genetics of the population. The genetic polymorphism that then ensues has been divided by Ford into two types, transient and balanced.

Transient polymorphism is found when the advantage conferred by the new mutant gene is unopposed. In these circumstances, such a gene occurs in an increasing number of individuals and the particular polymorphic form it produces becomes commoner at the expense of its alternative form until a uniform type is attained and the polymorphism has been extinguished. An example of transient polymorphism is the spectacular spread of black moths in industrial areas in Great Britain and elsewhere during the last 100 years (*see* MELANISM).

A balanced polymorphism arises when the increase of the controlling gene is checked. That is to say, the advantage it confers declines as it becomes commoner until, at some given proportion, the advantage is converted into a disadvantage and stability is attained. This type of polymorphism is controlled by some form of switch-mechanism, usually a pair of major genes or of supergenes (that is, a group of genes lying so near together on a chromosome, and therefore closely linked, that they act effectively as a single unit). Their segregation can give rise to contrasted forms without intermediates.

Moreover, a series of several alternative types of the same gene (multiple alleles) can produce a polymorphism involving a number of different phases. An excellent example of balanced polymorphism is provided by the pin, thrum and homostyle forms of the primrose. The pin and thrum types can reproduce only by crossing with one another, thereby maintaining diversity by means of outbreeding. The homostyle form, which is self-fertilizing, inbreeds with relative uniformity. One or the other of these mating systems is of advantage in differing ecological conditions. Another example occurs with the human blood groups. Some of the latter include several distinct polymorphs; for example, the ABO series, so well known for its importance in blood transfusion.

It is very seldom that all the effects of the major gene are useful, since they are diverse. Those that are advantageous will become dominant and those that are disadvantageous will become recessive. Thus the heterozygote will come to have none but favourable effects and will be at an advantage compared with both homozygotes, each of which will evoke some desirable and some undesirable qualities. This situation leads automatically to a balanced polymorphism. An example is provided by the gene producing the "sickling trait" in human red blood corpuscles. This may exist in a sizable proportion of the population in regions where subtertian malaria is common, since to a considerable extent it gives immunity to that disease. Most of the affected adult population is heterozygous; moreover, in its homozygous state the gene produces sickle-cell anemia, which is fatal to about four out of five children. Thus in malarial regions the gene is balanced by contending advantages and disadvantages, thus generating a polymorphism. Elsewhere the sickle-cell gene is of no value, while its dangers remain; in these circumstances it is eliminated.

POLYNESIA, the islands scattered over the eastern Pacific ocean within the vast triangle formed by the state of Hawaii to the north, New Zealand to the south and Easter Island to the east. Samoa Islands and Tonga are located at the western edge of this triangle and the Society Islands (with Tahiti the largest of the group) at the centre. Northeast of the Society Islands are the Marquesas Islands and between them the Tuamotu archipelago

stretches eastward to the Mangareva Islands. The Cook Islands lie to the west of the Society Islands and the Tubuai Islands to the south. What follows is an exposition of the physical and cultural anthropology of Polynesia. (For a discussion of such aspects as geography, geology, climate, wild life and modern government *see* PACIFIC ISLANDS.) Polynesian peoples, because of their pleasing appearance, natural graces and traditionally simple life among enchantingly fabled islands have long exerted a strong appeal on outsiders. Efforts to account for their presence in such remote land areas have been the pursuit of many authors and a continuing subject of scientific research.

Genetic and Linguistic Affinities.—People with Polynesian genetic traits have not been found outside of Polynesia except in some islands to the west which were more recently settled by Polynesians. The article OCEANIA describes with the aid of a map how successive hybridization of people of different racial strains moving out from Asia seems to have resulted in the formation of the populations met by the European explorers of the Pacific. The languages spoken by Polynesians are so similar from island to island that they practically constitute dialects of one language; this indicates that their speakers spread through the area not very long ago and without meeting other peoples. Hundreds of basic words, such as those for water, sky, land, star, house, canoe, bird, woman, parent and the numbers from one to ten are identical (except for regular sound shifts) and are readily traceable through islands westward to ancient Malay equivalents (*see* MALAYO-POLYNESIAN LANGUAGES). Furthermore, the spread of the language from west to east in Polynesia, and thence up to Hawaii and down to New Zealand, can be noted. This close linguistic affiliation with islands to the west of the Polynesian triangle and the total lack of linkage with any American Indian language have long convinced anthropologists of an Asian origin for the Polynesians.

The remarkable genetic homogeneity of the Polynesian people also argues for their having spread through the islands without encountering racially different populations. In prehistoric times migrants to these distant islands would, perforce, have come in such small numbers that they would have been absorbed by any established groups, whose physical type and language would then in all probability persist and predominate (*see* RACES OF MANKIND).

American Indian Influence.—The presence of the sweet potato in Polynesia, which botanists agree could only come from South America, has raised the question of what else may have been derived from the Americas, and how and when. In 1947 it was demonstrated by Thor Heyerdahl that balsa rafts such as were employed by the Inca Indians of Peru could reach Polynesia (*see* SHIP). A number of cultural parallels between ancient Peru and eastern Polynesia may be the result of cultural diffusion from that area. Advocates of the theory of a basic American-Indian origin for the Polynesians have offered details from myths and traditions which are too nebulous to be relied upon, and have seized upon cultural parallels from widely scattered parts of the Americas and Polynesia as if they constituted proof of historical connections. Most of this evidence will not bear careful scrutiny as demonstrating such connections. Polynesian-speaking people from the islands to the west of the triangle, however, must have firmly established themselves first in Polynesia as far east as Easter Island (within 2,000 miles of Peru); otherwise the language relationships would not be what they are. The argument that the islands of Polynesia could not be reached from the west because they lie in the face of prevailing winds and currents is untenable in the light of the numerous elements which could only have come directly from the direction of Asia.

Polynesian Vessels and Dates of Arrival.—A radiocarbon date of 124 B.C. was registered from charcoal found at a burial site in the Marquesas (*see* GEOCHRONOLOGY; RADIOCARBON DATING). Charcoal found with prehistoric pottery in a first attempt at archaeological digging in Samoa was dated at A.D. 9. Easter Island has produced campfire charcoal which gave a radiocarbon date of A.D. 360. Evidence of the introduction of Indonesian swine by at least A.D. 750 has been obtained in Hawaii from such

studies of radioactivity (*q.v.*).

Indications point to Tahiti and the Marquesas as having been settled several centuries before the Christian era, implying an earlier date (500 B.C. at the very least) for western Polynesia. It seems most improbable that Peruvians had developed their maneuverable sailing raft at this early time. On the other hand, ocean-sailing canoes typical of Oceania certainly had been developed by then; these are far superior in speed and maneuverability to anything American Indians produced. The twin-hulled sailing canoes of the Polynesians are entirely of Oceanic origin in design and in the terminology of their parts. (See *BOAT: Existing Boat Types.*)

Social and Political Organization.—In Polynesia the extended family was an almost self-sustaining unit with the head of the family being the oldest-born of the oldest-born (see *KINSHIP TERMINOLOGY: Distribution of Types of Terminology: Indonesia and Oceania*). The blood tie was all-important in social relations. Ideally the ruling chief of an independent population was the most direct descendant in the senior line from the head of the family which established itself on the land by virtue of first occupancy or conquest. A chief ruled through members of his family appointed as lesser officers. Independent chiefs rarely ruled over more than a district or a single island.

The families of the chiefs established themselves as a class apart from commoners and their position became hereditarily fixed. Their genealogies provided connections with creator gods from whom they derived their *mana* (*q.v.*); *i.e.*, sacred and superior qualities. Rigid *tabus* (restrictions), the infringement of which often involved the death penalty, were laid down to protect the chief from being familiarly approached by those not of his blood or rank, and to uphold the religious system which supported him (see *TABU*). A supreme chief in Hawaii and Tahiti owned all the land under his jurisdiction and had absolute power over his people.

In those islands where priests or talking chiefs participated in the government they wielded great influence. The Christian missionaries succeeded in overthrowing ancient religious practices only after they had converted the chiefs. Since chiefly power was deeply rooted in the old religion and made effective through religious *tabus*, the chiefs lost much of their hold on the people through this change. Those who let their land be taken over by foreigners lost even more power and prestige. In the 1960s Tonga and Samoa were practically the only Polynesian areas where hereditary chiefs retained even a degree of control. Throughout the islands governors or administrators have replaced the high chiefs, and ideas of democratic government are followed. However, in remote communities the family is still important politically, and family heads control local affairs.

Religion and Myths.—Considering their isolation, Polynesians had a most remarkable idea of the creation of the world. Chants honouring their chiefs trace their ancestors back to the major gods who were born of Mother Earth and Sky Father and who put the world in its present order. The chants relate that earth and sky have sprung out of a void and darkness where existed the Source or the Foundation (*Te Tumu*). Through the pairing of mental and natural phenomena, such as rumbling-foundations with shaking-foundations, and memory with reflection, emerge Earth and Sky. Born of the union of Earth and Sky in darkness were the gods Tane, Tu, Rongo and Tangaroa. Tane is a leader in separating this primal pair and bringing in the world of light. All this is dramatically and poetically expressed in beautiful cosmogonic chants. Myths, legends and traditions are embodied in chants whose meaning is often quite obscured through references to lost lore (see *MYTHOLOGY, PRIMITIVE*).

Chiefs approached the major gods at open-air temples with offerings and prayers for the well-being and success of themselves and their people. Favourable or unfavourable answers were determined by cloud omens and other signs of nature. In Hawaii and Tahiti the ritual of worship became so elaborate as to require schools of priests to carry them out. Human sacrifices were required for the war gods. Some chiefs, upon death,

were deified and thus continued to be called upon for aid. Each family and each profession had its own tutelary gods. No project was undertaken without enlisting the assistance of the gods. Sorcery was widespread and sorcerers greatly feared. Upon conversion of Polynesians to Christianity the ancient mythology was altered to agree with Biblical accounts. In New Zealand a Christianized native withdrew from his congregation to found a school of an esoteric cult around a god named Io who took on attributes of Yahweh, but functioned ritualistically like the ancient gods (see *MAORI: Religion*).

Material Culture.—The garment of Polynesian men was a loincloth or kilt and of the women a kilt made of fibres, fine matting or bark cloth. For protection against the cold, the Maori wore dogskin or bird-skin cloaks, or cloaks woven of flax. Some Polynesian chiefs had feather headdresses or helmets. A few Polynesian groups pierced their ears for ornaments.

Human hair necklaces supporting a whale tooth or pearl shell adorned those of rank; Hawaiians had bracelets of pig tusks. The European word tattoo for the art of tattooing (*q.v.*) is derived from the Polynesian term *tatau*, for the practice which was everywhere in evidence.

Houses were one-room buildings with thatched roofs and screened or open sides; several composed the household of a chief. People sat on the floor which was furnished with mats and head rests (see *DWELLINGS, PRIMITIVE: Oceania*). Cooking was done mainly in ground ovens, the food wrapped in leaves; it was served with wooden bowls and platters, and eaten with the fingers. Eastern Polynesians used stone food pounders. Pottery was absent except in prehistoric western Polynesia. Tools were hafted stone adzes, hammerstones, grindstones, digging sticks, carrying poles, pumice, coral or lava rubbing stones for shaping wooden objects, and coral or stone files for shaping fish-hooks. The main weapons were wooden spears and clubs, and the sling; the bow and arrow were not used in warfare. The outrigger canoe, which could negotiate shallow lagoons, land over reefs, and be easily hauled ashore, was essential to island life.

Economics.—Fishing and agriculture maintained the people; their regular diet was supplemented by the flesh of dogs and fowl, and on special occasions by pork. In a few of the islands human flesh was sometimes eaten, but as a gesture of bravado (see *CANNIBALISM*). Kava (*q.v.*), a narcotic beverage made from a variety of pepper plant, was a favourite of the chiefs and was served ceremonially. The cultivation of taro (*q.v.*) involved terracing and irrigation; sweet potato, banana, breadfruit and sugarcane were grown around the dwelling or in isolated, small gardens tended by family members.

Experts in the arts of canoe making, house thatching, bird catching, adze making, healing, dancing and other activities handed down their skills in their families. The best practitioners were drafted into the service of the high chiefs. The ruler levied taxes in the form of products of all sorts (such as bark cloth, dogs, pigs, food and feathers) for the support of his court, his priests and his professional soldiers. Both within the extended family and outside of it, goods were exchanged solely through gifts; stinginess in reciprocation was considered the meanest trait.

Arts and Crafts.—In what they fashioned Polynesians showed themselves to be consummate craftsmen and artists. Their finest skill and artistry was displayed differently in each island group. In Hawaii it was revealed in their magnificent feather cloaks and helmets; New Zealand was noted for carved meeting houses, Easter Island for gigantic stone statues and Samoans lavished their talents on the ornamental lashings of their council houses. Polynesian canoes reflected great resourcefulness in utilizing materials at hand and in adapting to island conditions of fishing and travel. The graceful war canoes of the New Zealanders were ornamented with bow and stern pieces intricately carved with open-worked double spirals.

Wooden images made by eastern Polynesians showed a complete mastery of sculpture. Because the images were grotesque symbols of idolatry to the Christian missionaries, their destruction was ordered; consequently few have survived. The western

Polynesians, with one or two minor exceptions, did not carve images but produced elegantly shaped ceremonial bowls supported on legs. The polished and carved war clubs of the Marquesans are among the prized possessions of museums. In Hawaii single whale teeth were fashioned into artful hook-shaped pendants to be worn by chiefs on human hair necklaces of hundreds of strands of fine square braid. (See WOOD CARVING: Primitive; JADE AND OTHER HARD STONE CARVINGS: New Zealand.)

The bark cloth manufactured by beating out the inner bark of the paper mulberry plant was of fine quality. In Samoa and Tonga it was decorated by rubbing designs raised on a plaque placed beneath the cloth and by painting other designs on in freehand. In Hawaii the bark cloth (tapa) was given watermark patterns in the final beating with heavy, carved mallets. Delicate geometric patterns were tastefully printed on tapa with bamboo stamps (see BARK CLOTH).

The feather cloaks of Hawaii represented a phenomenal amount of effort in the gathering of thousands of small, rare feathers, arranging them in tufts, and tying them in overlapping rows onto a fabric of exceedingly fine netting. The red, yellow and black feathers were arranged in triangle, diamond or crescent patterns in an over-all design. They were the most valued possessions of the Hawaiian chiefs and constituted the finest gift they could offer to distinguished visitors. Consequently more than 150 of these feather cloaks and capes have been preserved. The fact that no two have the same design is a tribute to the versatility of the Hawaiian artist. (See also PRIMITIVE ART.)

Music and Dance.—The ancient vocal music of Polynesia consisted of chants using one to four tones with one tone predominating; emphasis was on rhythm and pattern of words. Composers carefully set words together so that they would be most agreeable to the tongue and ear as well as appropriate to the theme. Love songs were rendered with irregular changes in pitch approaching melody; dance songs were initiated with calls. The popular musical instrument of the eastern Polynesians was the sharkskin-covered drum and of the western Polynesians, the wooden slit-gong; complicated and stirring rhythms were beaten on them. Also in accompaniment to dances, sticks were rhythmically beaten together, lengths of bamboo thumped on the ground, and gourds struck with the palm of the hand; in Hawaii only were gourd rattles brought into play. A bamboo nose flute was a popular serenading instrument; shell trumpets were used mainly to announce coming events. (See also MUSIC, PRIMITIVE.)

Stylized group dances were staged for the entertainment of visitors and returning friends or relatives. Teen-agers gathered at sequestered places in the evening for dances which gave expression to their emotions. In Hawaii dancing was such an important aspect of the culture that it became a profession under the training of experts in dancing, chanting and drumming, and rated a tutelary goddess. Performers took their positions standing or seated and usually kept them throughout the dance. While hip movements were important, conventional hand motions interpreted words. In Hawaii the movements were slow and graceful, but in most parts of Polynesia they were rapid and took abrupt turns.

As soon as the Polynesians became acquainted with European music they acquired melodic freedom, harmony and elements of western form. However, the rich quality of their voices, their keen sense of tone and rhythm, and fondness for improvisation brought about modifications which have set their music apart. Ancient dances are still known and followed, but most of them are lost; in their place have appeared dances with borrowings from far and wide accompanied by modern music, but still possessing the Polynesian flavour and serving some of the same functions.

POLYNESIAN LANGUAGE is spoken by fewer than 1,000,000 persons living among a group of Pacific islands which covers a larger segment of the globe than that encompassing the native speakers of any other single language. This one language has more than 60 closely related dialects and subdialects, but contrasts markedly with the many related Melanesian, Micronesian and Indonesian languages of the Austronesian (or Malayo-Polynesian) family of language, itself a member of the over-all Austric group. The Polynesian speech area is bounded by Kapingamarangi and Nukuoro Islands in the west through Hawaii to the north and New Zealand in the south through Easter Island to the east. The best known of the dialects include Hawaiian, New Zealand Maori, Samoan, Tongan, Tahitian, Niuean, Mangarevan and Tuamotuan.

Intensive exploration of the Pacific ocean by Capt. James Cook and his contemporaries of the last quarter of the 18th century accompanied a general awakening of interest in linguistic studies. The early discoverers collected vocabularies for both practical and scientific purposes. Following this period of discovery a world-wide expansion of Christian missionary activity and an accompanying need for translation of the Bible into native tongues led to a more systematic study of many of the Polynesian dialects. By the middle of the 19th century there were dictionaries, grammars and a full translation of the Bible for the most important island groups. Continuing interest in Polynesian history and culture has resulted in this language becoming one of the best known of the non-Indo-European languages from the standpoint of morphology and the techniques of translation.

Phonology.—Because of the paucity of consonants and the presence of at least ten meaningfully distinct vowel sounds, Polynesian is frequently termed a "vowel language." Each of the positional variant sounds /a/, /e/, /i/, /o/ and /u/ has about five recognizable variants of length in ordinary speech. For orthographic purposes these may be clustered together in two groups, distinguished by the use of the macron (¯) over the longer variants, as in New Zealand Maori *māta* "the face" and *mātā* "a heap." The many variant vowel lengths are patterned in relation to their linguistic environment, but exact rules of pronunciation have not been worked out. There are indications that the meaningful distinction between short and long vowels is a relatively recent phenomenon related to the loss of consonants with or without the coalescence of two or more shorter vowels.

Considerable alternation exists between certain vowels, notably /i/ ↔ /u/ and /a/ ↔ /e/. This shift may be freely variable within one dialect, as Hawaiian *imu* ↔ *umu* "earth-oven." Frequently it is fixed between dialects, as Rarotongan *meitaki* and Tahitian *maita'i* "excellent," but is never an established sound shift in the same sense that consonants are found to vary between dialects.

A comparison of data from 50 dialects suggests the following reconstruction of the proto-Polynesian consonantal system:

No modern dialect retains all of the original sounds, and there has been a marked tendency toward reduction in the number of consonants, especially in Eastern Polynesia. Only seven consonants appear to be present in Rurutuan, contrasting strongly with Tongan, the most conservative in the retention of consonants. Regular shift of consonants between dialects and the complete loss of certain consonants are characteristic of most dialects. Hence, the variations between dialects may be predicted and ancient or modern forms within one dialect may be derived with a fair degree of confidence. In Rarotongan when one finds that the term

for proto-Polynesian (PPN) **ahi* "fire" is *a'i*, and that PPN **faka* the causative prefix is 'aka, then it may be assumed that the term for PPN **tahi* "one" will be *ta'i*, as the shift from the PPN fricative to the glottal stop is obvious. Likewise, when it is determined that Rarotongan *tayata* "person" and *tapu* "sacred, forbidden" are in Hawaiian *kanaka* and *kapu* then it may be predicted that Hawaiian *maka* "face" will be *mata* in Rarotongan.

In some cases the sound shift was only partially completed at the time of European arrival, as in Mangaian where the velar stop /k/ has shifted to the glottal stop /ʔ/ only in certain words. In other cases there has been an irregular but complete loss of a sound, as in Hawaiian 'uala and Mangaian 'uara from PPN **kumara* "sweet potato," as well as in such words as PPN **tasi* "sea" which becomes *tai* in much of Polynesia.

There are no such distinctive voiced sounds as English /b/, /d/ and /g/, although in the past European recorders have misspelled terms such as *tapu* "forbidden" as *tabu*, and the island of

	Bilabial	Labiodental	Alveolardental	Velar	Glottal
Continuant	M	V	N	ŋ	ʔ
Stop	P		T	K	
Fricative		F	S		H
Flap			L/R*		

*Whether or not the sound was /L/ or /R/ or whether both existed as distinct meaningful sounds is not clear.

Porapora as *Borabora*. Polynesians cannot distinguish between the English speaker's "bad" and "bat," "tab" and "tap." Other than the apparently mnemonic device of the controversial Easter Island "talking boards" there was no pre-European system of writing. Those English and French missionaries who developed the present Polynesian systems of writing attempted to use their own European orthography. In most cases they did not understand the significance of the distinction between short and long vowels and the importance of the glottal stop, hence these were not provided for in the alphabets. These omissions seriously affect the ability to read aloud or to translate from the literature in most areas other than New Zealand.

Many foreign words have been adapted by the various dialects. The sound changes involved bring the new words into conformance with the Polynesian sound system by shifting any voiced sounds to sibilants or stops and by adding vowels to closed syllables; hence English "broom" and "towel" become Tahitian *purumu* and *tauera*.

Morphology.—The seemingly inexhaustible vocabulary is derived from a relatively limited number of basic words, which are capable of being used individually or combined with other basic words and frequently also with a small number of prefixes and suffixes. These basic words are usually, but not invariably, disyllabic in nature. All syllables end in vowels although the initial sound may be consonant or vowel. Stress or "accent" varies between areas and appears to be absent from certain dialects, notably Tahitian; traditionally it is stated to be upon the penultimate syllable, with certain exceptions related to vowel length. The New Zealand Maori base word *tupu* "to grow" when combined with the causative prefix *whaka* becomes *whakatupu* "to cause to grow"; *turipona* "the knee joint" is derived from *turi* "the knee" and *poma* "a knot, joint."

Basic words and syllables are frequently duplicated to form diminutives, pluralatives, frequentatives, and other variants of the base, as *paki* "to pat," *pakipaki* "to pat frequently," *papakaki* "to clap together"; or *manu* "a bird, small insect," *manumanu* "a very small insect." A few words are composed of a single sound or syllable, as New Zealand Maori *ā* "to compel, drive," *kī* "to be full."

Syntax.—Sentences are generally brief, and when spoken in full are composed of an initial predicative phrase followed by a subject, which may or may not be followed by one or more locative, directive or possessive phrases. The predication is the most significant part of the sentence and is spoken even when the nature of the situation permits the rest of the sentence to remain unsaid, as in Rarotongan *E kai! E kai ra!* "Eat! Eat on!"

Phrases are composed of one or more central "full words,"

usually (but not always) preceded and in some cases also followed by particles. Full words are those innumerable terms which have definable meanings within themselves. The very limited number of particles do not in themselves convey meaning, but serve only to place the predication or substantive as to identity, location and duration of the time, place or type of possession. A simple analogy would be to a brick wall, the bricks being similar to the full words of a sentence, the mortar similar to the particles which serve to bind the individual units into the whole structure. The Rarotongan base term 'aere "to go" (without connotation of direction) and *au* "I, ego" may be combined with particles as follows: *Kua 'aere au* "I went," *Ka 'aere au* "I shall go," *Tē 'aere nei au* "I am (in the process of) going."

Terms may be classified as full words or particles on the basis of specific meaning or function, but not individually as the traditional noun, verb and the like. A more useful classification relates to their use and position within the phrase or sentence. Many Polynesian full words may serve as predicative, substantive or the modifier of either. The initial full word of a phrase is invariably the most significant term with respect to meaning, and the words which may follow or the surrounding particles serve only to modify the basic concept. The first full word of the initial phrase of a sentence is the basis of the predication and the first full word of the second phrase is the subject, as *Kua tupu te taro* "The taro grew" and *Kua oti te tupu* "The growth stopped."

Polynesian predicatives lay greater stress upon the state of being than do English verbs and many of them must be preceded in translations by the phrase "was in the state of being." A particular source of confusion relates to the fact that a predicative may be either active or passive in nature as well as transitive or intransitive in any one of the four possible combinations. The full word involved may be modified by the passive suffix, one of a number of prefixes and by the intransitivizing particle. A secondary source of confusion relates to the sentence initial particle *E*, which is frequently mistranslated as equivalent to the English indefinite nominalizing particle "a, an," but in reality it is a predicative equational particle best translated as "is, am, was," as in Rarotongan *E tayata tiki koe* "You are truly a man."

Polynesian full sentences may be analyzed as follows (particles are in small capitals, full words are italicized):

In Hawaiian

ʻUA ho'ohiu 'IA	/	KA moku	/	I luga o KE alahukimoku
predicative phrase		subject		locative phrase

The ship was lifted (was lifted the ship) on to (on top of) the marine railway.

In Tahitian

'UA papa'i HIA	/	TE rata	/	Ē au
predicative phrase		subject		agentive phrase

The letter was written (was written the letter) by me.

Semantics.—Studies utilizing the technique of glottochronology reveal that Polynesian is possibly the most changeless of languages known to scholars. During more than 2,000 years following the settlement of Polynesia about 90% of such basic vocabulary terms as "fish," "fire" and "water" have retained the same form as that of the proto-language. The recording and translation of Polynesian has been considerably hampered by the lack of adequate orthography, and many dictionaries give the false impression of lack of precision of terminology as a result of having entered meanings belonging to several orthographically separate words under a single form. Despite the conservatism and the preciseness of vocabulary meanings, Polynesian makes extensive and richly complex use of analogy and imagery in oratory, poetry and folk lore. Despite the lack of written language there was an elaborate oral literature, with great stress upon preciseness of memorization and usage. Feats of memory witnessed by early explorers and later by anthropologists seem little short of phenomenal. Much of the memorization involved ancient prayers, religious ceremonies, folk tales and legends, but the most significant of all (and still a vital force in court cases) was the recounting of genealogy and secret family chants. This type of knowledge was the sole patent to land rights and verbal knowledge ruled in the event of dispute.

Together with other Oceanic languages Polynesian utilizes a

complex system of differentiating persons, with the individual distinguished from two persons as well as from a plurality, and the further differentiation of whether or not the person spoken to is included in the reference. Furthermore, the system of particles distinguishes persons and personified places or things from all others. All phenomena are divided into category of implicit and explicit connection when spoken of in the possessive sense, where for example one's blood kin are considered to be intimately a part of the speaker, hence are intrinsic, and one's wife is much less so and therefore explicitly "possessed."

Polynesian dialects, together with languages such as Javanese, utilize a form of courtesy reference or "chiefly language," as it is referred to in Samoa where its use is most elaborated. This separate vocabulary is used by commoners in addressing chiefs and their families and by the upper classes in discourse among themselves. The terms are frequently simple analogies, as when the chiefly women of Samoa are referred to as "flowers," but in other cases represent the retention of archaic terms. In central Polynesia a distinct vocabulary was also used for theological purposes by initiated priests, enabling them to perform ceremonies and render prayers not understood by noncommunicants. Learned aged men still are able to carry on conversations among themselves, to the bafflement of the younger generation.

BIBLIOGRAPHY.—Songs, tales, chants, genealogies have been preserved in the *Journal of the Polynesian Society*, Wellington, New Zealand; the *Memoirs and Bulletins* of the Bernice P. Bishop Museum, Honolulu, Hawaii; and in the *Bulletin de la Société des Études Océaniques*, Papeete, Tahiti. The most important dictionaries include C. M. Churchward, *Tongan Dictionary* (1959); Herbert W. Williams, *A Dictionary of the Maori Language*, 6th ed. (1957); Mary Kawena Puki and S. H. Elbert, *Hawaiian-English Dictionary* (1957); J. Frank Stimson with Donald Stanley Marshall, *A Dictionary of Some Tuamotuan Dialects of the Polynesian Language* (1960). (D. S. ML.)

POLYNOMIAL is used vaguely in elementary algebra to denote an expression that is the sum or difference of simpler expressions called monomials. Thus $x^2 + 2xy^3 + 5$ and $\sqrt{2}x^3 - (1/x) + a^2b$ would be called polynomials, while $2xy^3$ and $1/x$ would be monomials. For greater clarity this discussion follows the definitions of higher mathematics, in which monomial means the product of several variables raised to positive integral powers, and multiplied by a real or complex number (*q.v.*) called the coefficient; accordingly, $ax^p y^q z^r$ is a polynomial, where x, y , and z are the variables (there could be more or less than three), p, q , and r are positive integers, and a is the coefficient. The degree of the monomial is the sum of the exponents, here $p + q + r$; the degree of the monomial with respect to x alone is p . By definition a polynomial in several variables x, y, z, \dots , is a monomial or sum of monomials in these variables. The degree of the polynomial is the largest degree of any of the monomials occurring in it. Polynomials of degree one are called linear, of degree two quadratic, and of degree three cubic. Each monomial occurring in a polynomial is called a term of that polynomial. If the monomial is just a number, it is called the constant term of the polynomial. To illustrate these definitions: the expression $2x^2y - \sqrt{3}x + a^4b + c$, where a, b , and c represent numbers, is a polynomial of degree three in two variables, with three terms including the constant term $a^4b + c$; the expression $2 + 1/x + 3 \sin x$ is not a polynomial, since neither of the last two terms is a monomial of the accepted form. Occasionally the usage is relaxed to call such an expression as $a(1 + \sqrt{x})^2 + b(1 + \sqrt{x}) + c$ a polynomial of degree two in $(1 + \sqrt{x})$, or $\sin^3 x - \sin x$ a trigonometric polynomial in $\sin x$. Polynomials are added, subtracted, and multiplied by the usual laws of algebra and the result is always another polynomial. In general, however, when one polynomial is divided by another, the result is not a polynomial.

Algebraic Aspects.—In elementary algebra (*q.v.*) attention is (as a rule) confined to polynomials in only one variable. If $f(x)$ denotes the polynomial $a_0x^n + a_1x^{n-1} + \dots + a_n$, where the coefficients a_i are real or complex numbers and a_0 does not equal zero, then a basic problem (the main subject of the theory of equations) is to determine those real or complex values of x for which $f(x)$ is zero (see **EQUATIONS, THEORY OF**). Such values are called the roots of the equation $f(x) = 0$. The so-called funda-

mental theorem of algebra states that there always exists a root α of the equation $f(x) = 0$. From this it follows that $x - \alpha$ is a factor of $f(x)$; by repeated use of the fundamental theorem it can be shown that the polynomial has exactly n roots (not necessarily distinct) and that it can be written in the factored form $f(x) = a_0(x - \alpha_1)(x - \alpha_2) \dots (x - \alpha_n)$, where the factorization, except for the order of the factors, is uniquely determined.

Such a factorization of $f(x)$ into a product of linear polynomials of the form $x - \alpha_i$ may not be possible if the domain of the coefficients α_i of the linear polynomials does not consist of all complex numbers. Thus the polynomial $f(x) = x^2 - 2$ cannot be factored if the coefficients of the factors are restricted to the domain of rational numbers, but it can be factored if the coefficients are allowed to be real numbers, since $x^2 - 2 = (x + \sqrt{2})(x - \sqrt{2})$, and $\sqrt{2}$ is real but not rational. From this point of view, the fundamental theorem of algebra says that any polynomial with complex coefficients may be factored into linear polynomials, provided the factors are allowed to have complex coefficients; it would be false if a smaller coefficient domain were specified.

In modern algebra the problem of factorization is studied using as coefficient domain an arbitrary field (see **FIELDS**). It is proved that any polynomial in n variables with coefficients from a fixed field may be factored uniquely into the product of irreducible (not further factorable) polynomials with coefficients in that field.

Geometric Aspects.—Consider a polynomial $f(x, y)$ in two variables x and y with real coefficients. If a and b are two real numbers such that the polynomial becomes zero when a is substituted for x , and b for y , then the pair (a, b) is called a zero of $f(x, y)$. The set of all zeros of $f(x, y)$ defines a plane curve; the properties of the polynomial are reflected in the geometric properties of the curve and conversely. For example, if the polynomial is of the first degree, $ax + by + c$, then the associated curve is a straight line given by the equation $ax + by + c = 0$. If it is of the second degree, $ax^2 + bxy + cy^2 + dx + ey + f$, the curve is a conic section (*q.v.*). The zeros of a polynomial in three variables define in general a surface in three-dimensional space; if two such polynomials are considered together, their surfaces intersect in a curve in three-dimensional space. The natural generalization of these ideas to the study of the common zeros of a set of polynomials in n variables (viewed then as a locus in n -dimensional space) is the subject of algebraic geometry (*q.v.*).

Polynomials in Number Theory and Logic.—Diophantine analysis, a branch of number theory, is concerned with finding a set of integer zeros of one or more polynomials with integer coefficients (see **DIOPHANTINE EQUATIONS; NUMBERS, THEORY OF**). In geometric terms the problem is to find those points in space represented by integer coordinates that lie on the locus of zeros of the polynomial. Diophantine problems have an extensive literature going back to the Egyptians and Greeks, and have given rise to some of the most famous problems of mathematics (*e.g.*, see **FERMAT'S LAST THEOREM**).

There are striking modern applications of polynomials to mathematical logic, computer design, and allied problems. For example, information is usually transmitted over long distances in the form of sequences of digits (see **INFORMATION THEORY**). Disturbances in the line can alter some of the transmitted digits, and the garbled message may be unintelligible. Techniques of encoding have been developed in which the meaning of the message does not depend on each digit (just as in written material, sm of the ltrrs can be left out without disturbing the intelligibility). The successive members of a sequence of $n + 1$ digits are thought of as the coefficients of a polynomial of degree n . The encoding and decoding processes are then given as algebraic operations on these polynomials which produce new polynomials.

Analytic Aspects.—Polynomials in one variable are important in analysis (*q.v.*) because they form an especially simple class of function (*q.v.*). The derivatives and integrals of polynomials are themselves polynomials, and are readily calculated from simple formulas. Computation with polynomials does not require tables as do other simple functions (such as trigonometric and exponential functions). Such properties of polynomials make them useful for

approximating other functions. An applied mathematician or engineer who has empirical information in tabular or graphical form will frequently try to fit a polynomial to these data; i.e., will seek a polynomial of conveniently low degree whose values reasonably approximate those given, or, equivalently, one with a graph that lies close to the empirical curve. The data can then be handled conveniently through their polynomial approximation, rather than as an original table or graph susceptible only of numerical treatment. Formulas of numerical integration depend on fitting such polynomials to data (see CALCULUS OF DIFFERENCES). If the graph of the polynomial need only pass through a few points, the Lagrange interpolation formula, with which a polynomial of degree n is passed through $n + 1$ given points, can be used (see INTERPOLATION AND EXTRAPOLATION).

In theoretical and applied work it is frequently useful to expand a real function into a series of polynomials $p_i(x)$, where the i th polynomial is of degree i . A series (q.v.) representation for a given smooth function $f(x)$ can be written $f(x) = c_0p_0(x) + c_1p_1(x) + c_2p_2(x) + \dots$ to be valid in some interval of values for x . Here the coefficients c are chosen so that (if the series is broken off after the n th term) the resulting polynomial $c_0p_0(x) + \dots + c_np_n(x)$ will be the "best possible" approximation to $f(x)$ by a polynomial of degree n . A theorem due to K. T. W. Weierstrass states that an arbitrary continuous function can be uniformly approximated by a polynomial with any assigned degree of accuracy; the greater the desired accuracy, the higher the needed degree of the polynomial. For example, if $p_i(x)$ is taken to be $(x - \alpha)^i$ for some fixed real number α , a Taylor series results; if $\alpha = 0$, a Maclaurin series (see TAYLOR'S THEOREM). In either case the coefficients are given by $c_i = f^{(i)}(\alpha)/i!$ where $f^{(i)}(\alpha)$ denotes the i th derivative of $f(x)$, evaluated at α . If the function $f(x)$ arises as the solution to a differential equation (as is frequent in physical problems), other sets of polynomials are often more natural, and the corresponding coefficients c_i give a better description of $f(x)$ than the Taylor series coefficients. For example, problems of steady-state temperature or electrical charge distribution on a sphere may lead to Legendre's differential equation, and the solutions are expanded in terms of the Legendre polynomials (see SPHERICAL HARMONICS). Hermite and Chebichev polynomials are yet other classes of special polynomials arising as solutions to second order differential equations (see FUNCTIONS, SPECIAL: Orthogonal Polynomials).

POLYP, in medicine, is a general term used to designate any growth projecting from the wall of a cavity lined with a mucous membrane. This growth may have a broad base, in which case it is called sessile; or it may have a long narrow neck, the characteristic of a pedunculated polyp. The surface of a polyp may be smooth, irregular, or multilobular. The commonest locations of polyps in the human body are the nose, the bladder, and the gastrointestinal tract, especially the rectum and colon. Symptoms of polyps depend upon their location and size. There may be no symptoms, or there may be symptoms resulting from pressure or from mechanical obstruction of all or part of a lumen, such as the nose or bowel; they may occasionally bleed. Usually polyps are simple, benign growths, but a small percentage may be either precursors to cancers or may actually contain cancers. It is for this reason that it is best, when possible, to remove all polyps and examine them microscopically to determine whether further treatment is necessary. (J. A. Rr.)

POLYP, in zoology, is the name commonly applied to animals that bear tentacles and that are in some way attached to the substrate. In its broadest usage, the name applies to the individuals of such diverse animal phyla as the Bryozoa (Ectoprocta), the

Endoprocta, the pterobranch Hemichordata and the sessile members of the Coelenterata. More strictly the term is ordinarily applied only to members of the latter group. The word itself seems to have come into English from the French word *poulpe* ("octopus"). Polyps are illustrated and discussed in the articles COELENTERATA; HYDROZOA; ANTHOZOA; and SEA ANEMONE.

In the phylum Coelenterata the polyp represents one of the two body forms known in that group, the other being the medusa, or jellyfish. Polyps are of columnar form in general and with few exceptions are attached to the substrate or burrow into it. The attached end may be called the base. The free end of the polyp has a centrally located mouth, surrounded by tentacles in most instances. While most polyps have many tentacles—some large sea anemones have thousands—certain hydroids are exceptions; *Hydrichthys*, parasitic on fish, and the minute hydralike polyp *Protohydra* have no tentacles; *Monobrachium* has a single tentacle; and *Proboscoidactyla* has two.

The coelenterate polyp is not only morphologically different in the different classes but represents different stages in the life history of those animals. For example, the polyps of the Hydrozoa, the hydroids, are morphologically quite simple. They usually have small numbers of tentacles, as indicated above, are of small size and have a coelenteron (the gut) that is a simple sac. These polyps are usually the immature, attached stages of medusae, representing the adult, sexually reproducing form. Within the Hydrozoa, however, not all polyps bud off free medusae, and many polyps are known that are themselves the sexually reproducing stage. In almost all instances where hydroid polyps represent sexual adults, it can be shown nonetheless that the gonads develop in association with structures that represent reductions of the medusa. Thus it seems to be a safe generalization that the polyp of the Hydrozoa represents an immature stage in the life history of the members of that class.

Much the same seems to be true for the class Scyphozoa, whose members are the large medusae, or jellyfish, of marine waters. The polyps here are simple, but the coelenteron is divided into four compartments by four mesenteries, membranes that arise at right angles along the inner body wall. These polyps bud off the sexual medusae (the adults) much as in the Hydrozoa, and the polyps seem to represent only an attached immature stage in the life history of the group.

In the Anthozoa, on the other hand, no medusae are known and the polyps represent the adult individuals. Here the polyps may grow to very large sizes, up to about three feet in diameter, and internally become very complex through the possession of many mesenteries, which subdivide the coelenteron into many radially distributed compartments.

Polyps may occur as solitary individuals as in the fresh-water *Hydra* and many sea anemones, or they may occur as colonial aggregations. These colonies result from asexual reproduction by budding from the original polyp. Buds may arise apically, laterally or from stoloniferous growths from the basal region. Associated with colony formation, in many instances, especially among the marine hydroids, individual polyps in the colony assume different morphologies and have differing functions. Thus some individual polyps may be specialized for feeding (gastrozooids), for protection (tentaculozooids and dactylozooids) or for reproduction (gonozooids). Colonies possessing more than one type of polyp are said to be polymorphic; a good example is the common hydroid *Hydractinia* or *Podocoryne*. Another excellent example of a polymorphic colonial coelenterate is to be found in such organisms as the Portuguese man-of-war or any of its relatives (Siphonophora). Commonly among these free-floating colonial hydroids medusalike individuals may also occur that function as locomotory structures for the colony.

Polyps may occur as naked individuals or colonies, or they may have skeletons of various sorts. Among the hydroids, tough but flexible chitinous exoskeletons are common, and in many cases the polyp can contract completely within the surrounding skeletal cup. Skeletons of calcium carbonate or lime are also known among marine hydroids; the colonial polyps possessing these are called hydrocorals. The true corals, which are anthozoan polyps, also

have skeletons of lime (*see* CORAL). The polyps here, as in the hydrocorals, live in cups on the surface of the limey skeleton; when disturbed, the animals can contract into these protective structures. In the Anthozoa a number of colonial polyps are known, such as sea fans and sea pens, that have an axial, internal skeleton around which the colony grows.

Coelenterate polyps possess nematocysts (*see* COELENTERATA), with the aid of which they are able to capture other animals as food. Contact of a potential food organism, such as a small worm, mollusk or fish, with the tentacles of a polyp causes the nematocysts to discharge. Once a food item has been caught, the tentacles bend toward the mouth and the mouth opens in preparation to receive the food. Primary digestion of the food takes place in the coelenteron, where strong protein-splitting enzymes break the food down to minute particles. The cells lining the coelenteron then engulf these particles and final digestion takes place within the individual cells.

Polyps are for the most part restricted to marine habitats. In fresh water hydras are abundant and minute polyps of the fresh-water medusa *Craspedacusta* are found occasionally. The only other coelenterate polyp seen in fresh water is the widely distributed colonial hydroid, *Cordylophora*, which, while commonest in brackish waters, does occasionally appear in lakes and reservoirs. In marine habitats coelenterate polyps are abundant nearly everywhere. The open ocean supports many different siphonophores, while along the shores of the world hydroids, anemones and corals flourish, the last group, however, being most conspicuous in tropical waters. Somewhat below the reach of the lowest tides occur veritable gardens of sea fans and sea pens, particularly in warm waters, while even at the greatest depths of the oceans anemones and hydroids may still be found. The tallest hydroid polyp known, *Branchiocerianthus*, is usually restricted to waters more than one-half-mile deep, and the largest specimens recovered have been more than six feet long. *See* JELLYFISH; *see also* references under "Polyp" in the Index. (C. HA.)

POLYPHEMUS, the most famous of the Cyclopes, son of Poseidon and the nymph Thoösa. Odysseus, having been cast ashore on the coast of Sicily, fell into the hands of Polyphemus, who shut him up with 12 of his companions in his cave and blocked the entrance with an enormous rock. Odysseus at length succeeded in making the giant drunk, blinded him by plunging a burning stake into his eye while he lay asleep, and with six of his friends (the others having been devoured by Polyphemus) made his escape by clinging to the bellies of the sheep let out to pasture. *See* ACIS; CYCLOPS; ODYSSEUS.

POLYPHONY, a musical term, deriving from the Greek *polys*, "many," and *phōnos*, "sound," used of music in which the parts are independent of each other though forming an acceptable harmony. It is thus a synonym of counterpoint (*q.v.*), though the term counterpoint is generally associated with the technique of polyphonic music. The term polyphony is used of vocal works of the 16th century, *e.g.*, a polyphonic chanson, madrigal, or motet, as opposed to homophony (*q.v.*), used of music in which the conception is predominantly harmonic. It is also the converse of monophony, music consisting of one part alone, and monody (*q.v.*), a solo song with continuo. *See also* references under "Polyphony" in the Index.

POLYPTYCH: *see* ALTARPIECE.

POLYTECHNIC SCHOOL, generally a postsecondary school or institute in which the emphasis is on training in technology and applied science. The polytechnics of London derive from the institute founded (1882) by Quintin Hogg (*q.v.*). *See* TECHNICAL EDUCATION; *see also* VOCATIONAL EDUCATION.

POLYTONALITY, a term in music meaning the simultaneous use, common at the beginning of the 20th century, of different tonalities. Usually two different tonalities were used—this was known as bitonality—as in the passage for trumpets in C and F# minor in the second tableau of Stravinsky's *Petrouchka* (1911), expressive of the puppet's pathos. Alfredo Casella's *Pezzi infantili* are among the children's pieces in which this device was used. S. Prokofiev's *Sarcasms* for piano boldly juxtaposes the keys of F# minor in the right hand and Bb minor in the left, while Darius

Milhaud's *Saudades do Brazil* has a melody in C with an accompaniment in Ab major. Such combinations of tonalities may also be analyzed as highly inflected forms of chromatic harmony, the dissonances of which are eventually resolved. The passage from *Petrouchka* may be said to be based on the harmony of C# minor, to which it resolves, and the passage from Milhaud's work on the key of the accompaniment, in Ab. The simultaneous combination of three or more keys leads to harmonic or contrapuntal combinations that are even more difficult to define and which belong to the technique of atonality (*q.v.*). The technique of polytonality was first analyzed by Milhaud, who maintained that it could be traced back to the simultaneous use of two keys in a canon at the fourth of J. S. Bach.

See D. Milhaud, "Polytonalité et atonalité," *La Revue Musicale* (Feb. 1921).

POLYXENA, in Greek mythology, a daughter of Priam, king of Troy, and his wife Hecuba (Hekabe). After the fall of Troy, she was claimed by the shade of Achilles, the greatest of the Greek warriors, as his share of the spoils and was therefore put to death at his tomb. In postclassical times this story was elaborated to include a love affair between Polyxena and Achilles before the latter was killed.

POMBAL, SEBASTIÃO JOSÉ DE CARVALHO E MELLO, MARQUÊS DE (1699–1782), Portuguese statesman, master of the government throughout King Joseph's reign, and a reformer who ruthlessly exercised his despotic power, was born in Lisbon on May 13, 1699. Known for most of his life as Sebastião de Carvalho, he began reading law at Coimbra University, then embarked briefly on a military career, but eventually took up the study of politics and history on his own account and was appointed a fellow of the Royal Academy of History by King John V in 1733. After being ambassador in London (1738–43), he was sent on a diplomatic mission to Vienna in 1745, where he married Gräfin Eleonora von Daun (his former wife, Thereza de Noronha e Bourbon, had died in 1739). He returned to Portugal in December 1749.

On Joseph's accession (1750), the favour of the queen mother, Mariana of Austria, together with a recommendation by one of the former ministers, Luis da Cunha, brought Carvalho into the government as secretary for war and foreign affairs (from August 1750). Winning the king's confidence, particularly by his measures after the great earthquake (1755), he became chief minister in 1756. He was created conde de Oeiras in 1759 and marquês de Pombal (the name to be used in the rest of this article) in 1769.

Pombal claimed absolute power for the king. Atrocious sentences were pronounced by extraordinary tribunals: in 1757 on the people of Oporto who had rioted against the monopoly granted to the wine company; and in 1759 on the great nobles accused of complicity in the Sept. 3, 1758, attempt against the king's life, all of whom were tortured to death (though some were innocent). The whole Society of Jesus, apart from individual members who were arrested, was expelled from the Portuguese dominions (Sept. 3, 1759), and the church was subjected to royal control (1759 and 1764). All who opposed Pombal were thrown into prison.

Pombal nevertheless promulgated many economic and educational reforms. He promoted new industries and developed existing ones; *e.g.*, glass and textile manufactures, especially silk. He fixed the wages of peasant labourers (1756) and the size of agrarian properties (1769 and 1773). Chartered companies created by him were the General Company for Agriculture and for Wines of Alto Douro (1756), to handle the port wine trade; the companies of Pará and Maranhão (1754) and of Pernambuco and Paraíba (1759), for trade with Brazil; and the Algarve Fisheries Company (1773). He initiated commercial education (1759) and radically modernized the university (1772).

Joseph's death (February 1777) changed everything. Under the new queen, Maria I, political prisoners were freed; and Pombal, having resigned his ministry, faced charges of having abused his powers. He was severely interrogated during a judicial inquiry (October 1779–January 1780) and was found guilty; but the queen remitted all punishment save exile from Lisbon (August 1781). He died at Pombal on May 8, 1782. (DA. A. P.)

POMEGRANATE, the fruit of *Punica granatum*, a bush or small tree of Asia, which with a little-known species from the island of Socotra constitutes the family Punicaceae. Throughout the Orient this fruit has since earliest times occupied a position of importance alongside the grape and the fig.

King Solomon possessed an orchard of pomegranates; and when the children of Israel, wandering in the wilderness, sighed for the abandoned comforts of Egypt, the cooling pomegranates were

JOHN H. GERARD

(LEFT) WHOLE AND CUT FRUIT AND (RIGHT) LEAVES AND FLOWERS OF THE POMEGRANATE (*PUNICA GRANATUM*)

remembered longingly. Centuries later, the prophet Muhammad remarked sententiously: "Eat the pomegranate, for it purges the system of envy and hatred." It will thus be seen that this fruit is of exceptional interest because of its historic background.

While the pomegranate is considered to be indigenous in Iran and perhaps neighbouring countries, its cultivation long ago encircled the Mediterranean and extended through Arabia, Afghanistan, and India. The juicy subacid character of the ripe fruit makes it particularly agreeable to inhabitants of hot arid regions—precisely those areas in which the pomegranate attains its greatest perfection.

The ancient Semitic name *rimmon* was adopted by the Arabs as *rumman*, from which the Portuguese in turn formed *romão* or *roman*. From the early Roman names *malum punicum* (apple of Carthage) and *granatum* have come the modern botanical binomial and the common name *granada*, used in Spanish-speaking countries.

The plant, which may attain 15 or 20 ft. in height, has elliptic to lance-shaped, bright green leaves about 3 in. long, and handsome axillary orange-red flowers borne toward the ends of the branchlets. The calyx is tubular, persistent, 5- to 7-lobed; the petals lance shaped, inserted between the calyx lobes. The ovary is embedded in the calyx tube and contains several locules in two series, one above the other.

The fruit is the size of a large orange, obscurely six-sided, with a smooth leathery skin that ranges from brownish yellow to red; within, it is divided into several cells, containing many thin, transparent vesicles of reddish juicy pulp, each surrounding an angular elongated seed. The subtle flavour of the fruit is described by some Westerners as being delicately delicious, by others as insipid.

Presumably the plant was introduced into the New World by the early Spanish colonists. It is commonly cultivated in gardens from the warmer parts of the United States to Chile. Small commercial plantings have been made in California. Though the pomegranate will grow in a wide range of climates, good fruit is produced only where high temperatures and dry atmosphere accompany the ripening period. Deep, rather heavy loams appear to be the best soils. Seeds can readily be grown, but choice varieties are reproduced by cuttings and layerings. Commercial propagation is by hardwood cuttings 10 to 12 in. long, which can be rooted in the open ground.

The varieties of the pomegranate are numerous. Ibn al-Awam, a Moor who wrote in the 13th century, described about ten that were grown in southern Spain at that time. Varieties cultivated commercially in the United States include Wonderful, Sweet, and Acid. Several dwarf forms are grown for their handsome scarlet flowers.

(W. Po.)

POMERANIA: see POMORZE.

POMO, a group of North American Indians who occupied California from the upper reaches of San Francisco Bay northward about 80 mi., and from the Pacific Ocean inland approximately 80 mi. The population is estimated to have been from 8,000 to 16,000 at the time of first European contact. By the 1960s about 900 Pomo were reported living in California. The many autonomous villages, each with its own territory and its own language distinct from the others, were interrelated by trade, warfare, a common religion, and a chiefly language of the Hokan (*q.v.*) family unintelligible to the general population.

Pomo women are reputed to have made the finest basketry in the world. The baskets had many purposes, including cooking and housing; the finest were used as higher denominations of money (see *BASKET: Primitive Basketry*). The Pomo practised professions that required a lifetime of training; some of these were fishing, deer hunting, gambling, doctoring (including a highly developed psychotherapy), and money manufacturing. There was a formal economic and monetary system. They were well fed on a wide variety of foods, most important being acorns and horse chestnuts (leached before eating), fish, and deer. The hunters commonly knew every deer in the territory and maintained a balance between the herds and the available vegetation to keep the animals from straying outside Pomo territory. Their religion included the idea of a separate creation of their territory, animals, vegetation, and the Pomo people, as well as accounts of destruction by their gods and reestablishment afterward. See also MAIDU.

Williams, *Pomo Indian Myths* . . . (1954); B. W. Aginsky, "The Pomo: A Profile of Gambling Among Indians," *Annals of the American Academy of Political and Social Science* (May 1950); United States Department of the Interior, *United States Indian Population and Land* (1961). (B. W. A.)

POMONA, Roman goddess of tree fruit—apples, cherries, etc. (*i.e.*, *poma*). She is obviously an old Italian goddess, for she had a special priest at Rome, the *flamen Pomonalis*. Although there is no festival in her honour in the calendar, there was a sacred area, the Pomonal, 12 mi. from Rome in the direction of Ostia. Ovid tells the story (*Metamorphoses* XIV, 623 ff.), perhaps of his own making, that she spurned all her woodland would-be suitors. The god Vertumnus, however, after wooing her in many disguises finally gained his suit. She is also said to have been associated with the agricultural deity Picus.

BIBLIOGRAPHY.—G. Wissowa, *Religion und Kultus*, 2nd ed., pp. 198 ff. (1912); W. Ehlers, "Pomona," in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*; A. M. Young, *Legend Builders of the West* (1958). (R. B. Lo.)

POMONA or MAINLAND (the latter is the more correct name), the central and largest island of the Orkneys, Scot. Pop. (1961) 13,495. Area, including smaller adjacent islands, 201.6 sq.mi. (521 sq.km.). It is irregularly shaped, and Kirkwall bay and Scapa Flow, cutting into the land on the north and south respectively, at one point reduce the width to less than 2 mi. The western coast is almost unbroken, but the eastern and southern shores are considerably indented. Ward hill (881 ft. [269 m.]) in the south is the highest peak in the island. There are numerous lakes, some of considerable size and most of them abounding in trout. Kirkwall (*q.v.*), the capital of the Orkneys, and Stromness (*q.v.*) are the only towns. Antiquities include Pictish *brochs*, chambered mounds and weems, or underground dwellings afterward roofed in. North-east of Stromness, and within a mile of the standing stones of Stenness, lies the great barrow or chambered mound of Maeshowe. It is a blunted cone 300 ft. (91 m.) in circumference, and at a distance of 90 ft. (27 m.) from its base is encircled by a moat. The ground plan shows that it was entered from the west by a passage, leading to a central apartment, the walls of which ended in a beehive roof. The barrow is variously ascribed to the Stone Age and to 10th-century Norsemen. The stone circles forming the Ring of Brogar and the Ring of Stenness, traditionally pagan temples, lie 4½ mi. (7 km.) NE of Stromness. The former stands

on a raised circular platform of turf, surrounded by a moat and a grassy rampart. The ring originally comprised 60 stones, varying from 9 to 14 ft. (3 to 4 m.) in height, set up at intervals of 17 ft. (5 m.). Only 27 are now erect. The Ring of Stenness is of similar construction, and 150 yd. (137 m.) N of it formerly stood the monolith called the Stone of Odin, pierced by a hole at the height of 5 ft. (1½ m.), through which persons swearing a particularly binding oath clasped hands. At the bay of Skaill is the Neolithic village of Skara Brae (q.v.), where evidence has been found of more than one occupation, with perhaps hundreds of years between. On Marwick Head stands the Kitchener memorial, erected to the memory of Lord Kitchener, drowned off Mainland in 1916. See also ORKNEY ISLANDS.

POMONA, a city of California, U.S., is in Los Angeles County 30 mi. E of Los Angeles (q.v.). A group of promoters purchased lands for town and agricultural development in 1875. The settlement, which the founders named Pomona for the Roman goddess of fruit, grew slowly until after 1880 when the sinking of deep wells provided a dependable source of irrigation water and made it the centre of a prosperous farming and fruit-raising region. The southern California real estate boom of 1887 brought rapid growth to Pomona; the town was incorporated in 1888 and the census of 1890 recorded a population of 3,634. Pomona remained the trading centre for a growing region which produced oranges, lemons, and walnuts as well as deciduous fruits, field crops, and livestock. The Southern Pacific, Santa Fe, and Union Pacific railroads, which passed through or near it, gave a wide outlet for its crops. Pomona's agricultural character was recognized by the location of the extensive grounds of the Los Angeles County Fair there.

World War II and the years following brought major changes to Pomona. Its population, which had been 20,695 in 1930, grew to 67,157 in 1960. (For comparative population figures see table in CALIFORNIA: Population.) This was partly due to the expansion of Los Angeles which brought Pomona into commuting range of the city. It was even more the result of the industrialization of Pomona itself. There had been some manufacturing in Pomona since 1902, notably of water pumps necessary for the irrigation of the fruit groves. During and after the war, however, the number and size of industrial plants increased steadily. Naval ordnance, guided missiles, aircraft parts, pumps, paper products, and tile were manufactured. Hundreds of acres of orange groves were replaced by single-family dwellings, and citrus culture was no longer the prime activity of the region. The Kellogg-Voorhis campus of the California State Polytechnic College was established in 1938 just west of Pomona. The city has a council-administrator form of government, in effect since 1949. (J. H. K.)

POMORZE (POMERANIA), the southern coastland and hinterland of the Baltic Sea from the lower Vistula in the east to the lower Oder in the west. The Slavonic name (*po*, "along," *morze*, "sea") was latinized first as Pomorania, later as Pomerania, and germanized as Pommern. Political developments contributed in extending the name west of the Oder as far as Stralsund, with the island of Rügen (Rugia).

Physical Geography.—Pomorze is a flat country lying generally about 300 ft. (91 m.) above sea level, though its centre is traversed by a west-east range of morainic ridges rising in many places to 650 ft. (198 m.), at some points to more than 975 ft. (297 m.) and at one, the Wiezyca Hill (near Koscierzyna), to 1,079 ft. (329 m.). Off the west coast, which is irregular, lie the islands of Uznam (Usedom) and Wolin (Wollin); the eastern coast is smooth in outline, but behind the dunes or accumulations of silt there are many lakes. Altogether, hundreds of lakes, large and small, are to be found, the largest being Lebsko, Dabie, Miedwie, and Gardno. There are many small rivers, some of which flow into the Baltic (Leba, Slupia, Parseta, Rega), some into the Vistula (Wda), some into the Notec (Brda, Glda, Drawa), and some into the Oder (Ina, Plona).

The soil is for the most part thin and sandy, with patches of good land along the river valleys; there are also rich meadows and pastures and, on higher ground, dense forest, mainly coniferous. Poland's ports are situated in Pomorze: in the chief ports,

Gdąnsk (Danzig), Gdynia, and Szczecin (Stettin), important ship-building industry is concentrated, while Kolobrzeg (Kolberg), Darlowo (Rügenwalde), and Ustka (Stolpmünde) are mainly centres of fishing industry.

History.—In prehistoric times the southern coast of the Baltic seems to have been occupied by Celts, who made way for various tribes of Germanic stock. These in turn were replaced, about the end of the 5th century A.D., by Slavs: the Pomorane or Pomorzanie settled between the Vistula and the Oder, while the Polabs were occupying the land between the Oder and the Elbe (Labe).

Almost the whole of Pomorze was included in the territory of Mieszko I (d. 992), Poland's first historical ruler; and his successor Bolesław I the Brave (992–1025) founded a Polish bishopric at Kolobrzeg in A.D. 1000.

At that time there existed a local dynasty that ruled over the whole of Pomorze and also in what was later known as Mecklenburg. Swiatobor or Svantibor, duke of Pomorze, who died in 1107, divided his land among his three sons: Bogusław (Bogisław or Bogislav) received the eastern part (Pomerania Ulterior, later known as Hinterpommern), with Gdąnsk; Warcisław (Wratisław) received the western part (Pomerania Citerior, or Vorpommern), with Wologoszcz (Wolgast); while Ratibor was the ruler of the central part, with Szczecin. The dukes recognized Polish suzerainty during the reign of Bolesław III (1102–38); and about 1119 eastern Pomorze was included in the Polish Kujawy diocese of Kruszwica. Later this episcopal see was transferred to Włocławek. In 1140 a new bishopric for western and central Pomorze was created at Wolin, and in 1176 it was transferred to Kamien (Kammin), replacing that of Kolobrzeg.

In 1181 both western and central Pomorze had to accept the protection of the German *Reich*, and in 1225 the Kamien diocese was transferred from the Polish archbishopric of Gniezno to the German archbishopric of Magdeburg. In the following five centuries these two parts of Pomorze were united under a single duke for two periods (1264–95 and 1478–1532) but generally remained separated under two branches of the same family. From the 13th century the country was opened to German immigrants, and this resulted in the germanization of the towns and later of the nobility and of the countryside.

In eastern Pomorze (Gdąnsk), Duke Mściwoj I (1209–20) was succeeded by his son Swietopelk (1220–66), who had to defend his lands against the Teutonic Order, which in 1226 succeeded in establishing itself east of the lower Vistula. Swietopelk's son, Mściwoj II, having no issue, agreed in 1282 that after his death his dukedom should become part of Poland; and this came about in 1294. In 1308, however, eastern Pomorze was conquered by the Teutonic Order; but Poland's reconquest of it (1454) was recognized by the Order in 1466.

Western and central Pomorze remained under the suzerainty of the German *Reich*. In 1625 Bogusław XIV once more united the duchies of Wolgast and Stettin, but he died without issue in 1637 and the whole succession passed to Brandenburg. At the peace of Westphalia in 1648 it was again divided with Sweden, which took Vorpommern, that is, the part west of the Oder, with Stettin, leaving the remainder, Hinterpommern, as far as the frontiers of Poland, to Brandenburg. In 1720 Stettin and the southern part of Vorpommern, as far as the Peene (Piana) River, were ceded to Brandenburg, but the northern part, with Greifswald, Stralsund, and Rügen, remained Swedish until 1815.

In the meantime, Polish Pomorze was annexed by Brandenburg-Prussia in 1772 and renamed West Prussia (Westpreussen). It was recovered by restored Poland in 1919, with somewhat smaller boundaries, and until 1939 constituted the province of Pomorze, with its chief town at Toruń. Its area was 6,327 sq.mi. (16,387 sq.km.) and in 1921 it had 939,000 inhabitants.

In 1815 Vorpommern and Hinterpommern were united in one Prussian province of Pommern, with its chief town at Stettin. That province had an area of 11,663 sq.mi. (30,207 sq.km.) and its population in 1926 was 1,897,166.

After 1945 almost the whole of historic Pomorze, except its section west of the Oder, became part of Poland. It was then divided into three provinces (*województwa*) of Gdąnsk, Bydgoszcz, and

Szczecin. On June 1, 1950, a fourth province of Koszalin was formed in the eastern part of that of Szczecin. The four provinces of Pomorze cover together an area of 24,103 sq.mi. (62,427 sq.km.). Their population in 1946 was 2,041,170, including 619,287 Germans. In 1960 it was 4,367,400, practically all Poles. (K. Sm.)

POMPADOUR, JEANNE ANTOINETTE POISSON, MARQUISE DE (1721–1764), fourth and most famous of the acknowledged mistresses of Louis XV of France, was born in Paris on Dec. 29, 1721. Of lower middle-class parentage, she owed her fortune in the first instance to her father's misfortune and her mother's devotion and resource. Her father, François Poisson, had been employed by the Paris brothers, influential army contractors and bankers; and in 1725, when they were involved in a temporary financial failure, he had to flee abroad, where he remained for eight years. In the interval his wife, to support her family, found a rich protector in C. F. Le Normant de Tournhem, who gave her daughter an expensive education and arranged her marriage, in March 1741, to his nephew, C. G. Le Normant d'Étioles. The young girl was by then already remarkable for her beauty: although tall, her figure was perfect, her complexion clear, her hair chestnut, and her eyes animated and expressive. Her talents as a hostess in the world of finance and fashion, her intellectual interests, her musical and acting ability soon attracted attention in Paris, where she entertained some of the leading writers of the day, including Voltaire, Montesquieu, Fontenelle, and the elder Crébillon.

THE BETTMANN ARCHIVE

MARQUISE DE POMPADOUR, DETAIL OF PORTRAIT BY MAURICE QUENTIN DE LA TOUR

Early in 1745, Madame d'Étioles attracted the attention of Louis XV at a masked ball at Versailles. During his absence in the summer on the Fontenoy campaign, he created her marquise de Pompadour; and after his return she was formally presented to the queen at Versailles in September and so recognized as the king's *maitresse en titre*.

Though the dauphin, the aristocratic court, and the Jesuits frowned on her, Madame de Pompadour soon established her ascendancy over Louis XV. She provided him with distractions from the affairs of state, sharing his mania for building and landscape gardening, introducing amateur theatricals to the court, and giving a stimulus to art and literature. She continued and increased her contacts with the *philosophes*—securing Voltaire the post of historiographer royal and admission to the Académie Française, having François Quesnay, founder of the Physiocratic School of economists, as her physician, and affording protection and encouragement to the editors of the *Encyclopédie*. Her exquisite taste was shown in the interior decoration of her various residences, particularly that of Bellevue, near Saint-Cloud, in the enlargement of the Hôtel d'Evreux (now the Élysée palace), and in the building of the École Militaire by J. A. Gabriel. She also took a personal interest in the supervision of the state china manufactory at Sèvres and was responsible for the appointment of her brother, Abel Poisson, as supervisor of buildings (1751); he proved extremely competent, and was created marquis de Marigny in 1754. Her political influence has been exaggerated: it was mainly exerted in internal affairs, in the appointment and dismissal of ministers, and in the animus that she displayed against the Jesuits. Though Austria's secret negotiations for the reversal of alliances which began the Seven Years' War were initially conducted through Madame de Pompadour's agent, the abbé François Joachim de Bernis, her responsibility for the Austrian treaties of alliance with France in 1756 and 1757 was much less than formerly supposed. Her physical liaison with the king had terminated about 1751, but she still continued as his friend and adviser till her death, at Ver-

sailles, on April 15, 1764.

In her later years Madame de Pompadour became more devotional in her habits and acquired a securer status at court after her appointment in 1756 as lady-in-waiting to the queen.

POMPANO, any of a number of coastal fishes in the jack family (Carangidae), especially several species of *Trachinotus*. Pompanos occur in all warm seas. They are deep-bodied with smooth sides. The first dorsal fin is composed of seven or fewer very low spines; the second dorsal and anal fins are of about equal length and longer than the abdomen, and their highest rays are usually more than three-fourths the length of the head.

The common pompano of eastern America (*Trachinotus carolinus*) ranges from North Carolina to Brazil; it reaches a length of about 18 in. and a weight of about 2 lb. It is perhaps the most delicious of the pompanos, and one of the most costly food fishes of the United States. The African pompano (*Alectis ciliaris*), another carangid, has long streamers, extending from its dorsal and anal fins, which disappear with age. *Diapterus olisthostomus*, of the mojarra family (Gerridae), is called the Irish pompano; it occurs from the West Indies to southern Florida. The Pacific, or California, pompano (*Palometa simillima*) is of the butter-

NEW YORK ZOOLOGICAL SOCIETY

LONG-FINNED POMPANO OR PALOMETA (*TRACHINOTUS GLAUCUS*)

fish family (Stromateidae); it occurs from San Diego to Puget Sound. (L. A. Wd.)

POMPEII, an ancient city of Campania, Italy, 14 mi. SE of Naples, near Mt. Vesuvius, built on a spur formed by a prehistoric lava flow to the north of the mouth of the Sarnus (modern Sarno) River. Pompeii was destroyed, together with Herculaneum and Stabiae (*qq.v.*), by the eruption of Vesuvius in A.D. 79; the circumstances of their preservation make their remains a unique document of Greco-Roman life. The modern town of Pompei (pop. [1961] 20,142) lies to the east; it contains the basilica of Sta. Maria del Rosario, a pilgrimage centre.

History.—Pompeii was a suitable occupation site for the first Oscan inhabitants of Campania, and from the 8th century B.C. the Sarnus mouth must have offered a good anchorage to the earliest Greek navigators. However, archaeological evidence does not go back beyond the 6th century, when, to judge from the remains of an archaic Doric temple in the triangular forum, Pompeii came under the rule of the Greeks of Cumae. The Etruscan occupation mentioned by Strabo has not been conclusively proved by excavation. Toward the end of the 5th century Campania was invaded

by Samnite peoples. Pompeii was conquered and thereafter rebuilt in Italic style, its constitution, language (Oscan), customs, and religion being those of the Samnites.

In 310 B.C. a Roman fleet landed at Pompeii but was driven off. The Pompeians took little part in the Samnite and Hannibalic wars, but they intervened vigorously in the Italic revolt against Rome (the Social War, or war of the *socii*); in 89 Pompeii was besieged, and probably captured, by L. Cornelius Sulla. In 80 B.C. it became a Roman colony with the name of Colonia Cornelia Veneria Pompeianorum, from Sulla's name and the cult of Venus Pompeiana. Publius Sulla, the dictator's nephew, was put in charge of the new organization of the colony; an echo of this troubled period survives in Cicero's defense of Publius Sulla.

Pompeii soon became romanized in language, constitution, and architecture. In A.D. 59 a riot in the amphitheatre between Pompeians and Nuceria resulted in several deaths, and the Roman Senate banned gladiatorial shows there for ten years. The city was the commercial, agricultural, and maritime centre of the Sarnus valley, with a population estimated at 20,000–22,000, when, in 62 (or possibly February 63—Tacitus and Seneca give different dates), it suffered a disastrous earthquake. Reconstruction was still in progress when, on Aug. 24, 79, there followed the violent eruption of Vesuvius described in two letters (vi, 16 and 20) from an eyewitness, Pliny the Younger, to the historian Tacitus. Pliny the Elder, commander of the Roman fleet, rushed from Misenum to help the stricken population and to get a close view of the volcanic phenomena, and died at Stabiae. Falling lapilli, pumice, and hot scoriae (for terms, see *VOLCANO*) covered Pompeii over six feet deep, causing the roofs of the houses to fall in. A rain of ashes followed, reaching a depth of five to six feet and preserving in a pall of ash the bodies of the inhabitants who perished sheltering in their houses or trying to escape toward the coast or by the roads leading to Stabiae or Nuceria; many were suffocated by the ash. Thus Pompeii remained buried under a layer of lapilli and ash 12 ft. or more deep, overlaid in time by a further 6 ft. of fertile earth.

History of the Excavations.—In the late 16th century, buildings and paintings in the hill called La Civita were discovered during the construction of a water channel from the Sarno. Systematic exploration was begun in March 1748 by the king of Naples, Charles of Bourbon (later Charles III of Spain). The finds of the excavations carried out before 1763 were limited to the area of the amphitheatre, the Via delle Tombe, the Villa of Julia Felix, the so-called Villa of Cicero outside Porta Ercolano, and the Temple of Isis. In 1763 the discovery of an inscription identified the ruins as those of Pompeii.

At first the excavators looked mainly for paintings, statues, and precious objects. But a real interest in the architecture was awakened with the discovery of the first large public buildings, the fine houses, and above all the forum. More systematic excavation, together with preservation and restoration, began in 1860 under the direction of G. Fiorelli, who also originated the method of obtaining impressions of the bodies of the victims by pouring plaster of paris into the hollows left in the ash, a system also adopted for wooden house frameworks, domestic furniture, and trees. After 1895, paintings and mosaics were left *in situ*, including those of the House of the Vettii, the House of the Silver Wedding, the House of the Golden Cupids, the House of M. Lucretius Fronto and, more recently, the houses and shops in the Via dell' Abbondanza, the Villa of the Mysteries, the House of the Menander, and the great *palaestra* (sports ground). Among the restorations of architectural interest which have been carried out is that of the *tribunal* of the basilica.

After World War II, in 1951, intensive excavation was resumed south of the Via dell' Abbondanza, as far as the inner rampart of the walls, bringing to light some fine houses, such as the House-Villa of Julia Felix (excavated and buried again in the 18th century), the House of Venus Marina, the House of the Fruit Orchard, the House of the Beautiful Impluvium, and numerous minor rustic and commercial dwellings. Also since 1951 the external line of the walls has been largely freed from the debris of former excavators outside it. As a result, the Porta di Nocera

and a monumental cemetery flanking the road from Pompeii to Nocera Inferiore have been discovered. More than three-fifths of the city has been uncovered, not counting the villas and cemeteries outside it.

Topography and Construction Periods.—Pompeii was built upon a lava flow that sloped sharply down from north to south; in the south and west the lava flow formed a steep wall which constituted a natural bulwark toward the sea. The city was level in the southwestern sector, in which were the forum and the more important public and religious buildings. There were other minor terraces, for instance around the Temple of Venus in the southwest and the triangular forum in the southeast (see plan). The extreme southeastern section of the perimeter wall was reserved, because of its flat surface, for the construction of the amphitheatre; in the other parts of the city the construction of buildings had to overcome the slope of the ground by means of embankments and cryptoporticoes with arches.

The Via Stabiana, which crosses the city from northwest to southeast, from Porta Vesuvio to Porta Stabia, passes along the line of the steepest slope and is crossed at right angles by two other main streets, the Via di Nola and the Via dell' Abbondanza. Corresponding with the main roads there are seven gates, named according to their position: Porta Marina, Porta Ercolano, Porta Vesuvio, Porta di Nola, Porta di Sarno, Porta di Nocera, and Porta Stabia; the existence of the Porta di Capua in the north is still doubtful. The town is conventionally divided into nine regions, each consisting of several *insulae* (blocks) which normally include several dwellings; consequently every building in Pompeii is known by the number of its region, its *insula*, and the room with the main entrance.

The plan of the town is less uniform geometrically than those of Neapolis (Naples) and Herculaneum; presumably at Pompeii the building plan evolved gradually from an Oscan nucleus, subsequently enlarged during the periods of Greek, Etruscan, and Samnite influence.

The construction periods can be divided approximately into the following:

1. Pre-Samnite (500–420 B.C.), in which limestone materials, almost exclusively from alluvial deposits of the Sarnus, were used, and building was in *opus quadratum* (stone blocks; see *ROMAN ARCHITECTURE: Building Techniques*). The Doric temple in the triangular forum and the pre-Samnite walls belong to this period.

2. First Samnite (420–250 B.C.), in which mainly limestone was used and construction in tufa was begun, employing *opus quadratum* and *opus incertum* (concrete faced with irregular pieces of stone) techniques. This period includes the restoration of the perimeter walls, the construction of houses with limestone atria, the regular plan of some quarters of the town, and the completion

EDWIN SMITH

VIA STABIANA

of the network of roads, besides the building of the Temple of Jupiter.

3. Second Samnite (250–80 B.C.), in which tufa is chiefly used, while Hellenistic Greek influence is noticeable in the architecture. In this period took place the second and third restorations of the walls, with the addition of the towers, the building of the forum, the large theatre, and, later, the porticoes of the forum, the Temple of Apollo, the triangular forum, the small *palaestra* and the Stabian baths. The original foundations of the basilica and the decoration of the floors of the houses with mosaics also fall within this period.

4. Beginning of Roman colonization (80–c. 23 B.C.), when *opus reticulatum* (concrete faced with regular pieces of stone) and brick facing were first employed. The forum baths were built, as well as the *odeon* (small theatre), the amphitheatre, the Temple of Venus and the Temple of Zeus Meilichios.

5. Augustan and Julio-Claudian (23 B.C.–A.D. 62), in which *opus reticulatum* was extensively used. Marble was used for the facing of buildings, while the houses were rich in decorative features and paintings with Greek subjects. New public buildings were constructed along the southern and eastern sides of the forum, and existing buildings were freshly decorated.

6. First Flavian (A.D. 62–79), in which there was a marked use of *opus latericium* (brick-faced concrete) in the reconstruction of the buildings damaged in the earthquake of 62. The Temple of Isis was rebuilt and the central baths and the *aulae* of the curia were begun.

Public and Private Buildings.—The most important public monuments of Pompeii, except for the baths and the amphitheatre, were grouped round the civil forum and the smaller triangular forum. The civil forum was rectangular and surrounded by a portico with a gallery above it. Around it are: the Temple of Jupiter, sacred to the Capitoline triad (Jupiter, Juno, and Minerva) after Pompeii became a *colonia*, severely damaged by the earthquake; the Temple of Apollo, the best preserved in Pompeii; the basilica, seat of the law court, preceded by a *chalcidicum* (vestibule) with tufa pillars, and divided inside into three naves by a magnificent colonnade; on the inner wall rises the pillared front of the *tribunal*, inspired by the purest models of Hellenistic Greek architecture, while the covered court of the basilica already fore-

shadows the Vitruvian style; the *sacrarium* dedicated to the *lares* of the city; the Temple of the *genius* of Augustus (sometimes called Temple of Vespasian); the *curia* (council house), opposite the Temple of Jupiter; the *macellum* or covered market; the great building of Eumachia, seat of the corporation of the manufacturers and cleaners of cloth.

The triangular forum is one of the oldest centres of the city. In it, along the side of the terrace of the 6th-century Doric temple, was developed, between the 3rd and the 1st century B.C., a group of buildings intended for public entertainment, particularly the small *palaestra*, the large theatre, and the small covered theatre, or *odeon*. Thus the triangular forum has the noncommercial character of a Hellenistic city quarter, while the civil forum was built in a markedly Italic and Roman style and was the centre of the daily life of the city.

At the extreme southeast angle of the built-up area rose the amphitheatre, perhaps the oldest so far known (*see AMPHITHEATRE*). Great flights of stairs in a double ramp constructed externally lead to the top row, where there are large stone rings to receive the framework for the support of the *velarium* (canopy). To the west of it is the great *palaestra*.

The baths (*thermae*) of Pompeii include the Stabian baths, the forum baths, and the unfinished central baths, besides many private baths preserved in the nobler houses of the city; they are important examples of both architecture and decoration (*see BATH*).

In Pompeii it is possible to follow the evolution of the ancient house through at least five centuries, from the primitive Italic house, closed externally and open on the inside, overlooking the atrium, which is surrounded by the living rooms, to the house clearly showing Hellenistic influence in both its decorative and functional elements. The House of the Surgeon, near Porta Ercolano, of Italic type, yielded a large set of surgical instruments. Houses of the Samnite period, enlarged or improved in the republican and imperial periods, include the House of the Faun, which covers a whole *insula* and has two entrances and two atria; the House of the Labyrinth, in which the architectural decoration of the walls is a background for the main architecture, an example of the second style of painting (*see below*); the House of Meleager; the House of the Silver Wedding; the House of the Centenary; and the House of Cornelius Rufus.

In the last republican period and in the Augustan age stucco facing of the houses began and porticoes had pictorial decoration. Brick columns also began to appear, evidence of the prevalence of commerce in Pompeii, which built up an enriched middle class with more exacting if perhaps less refined tastes than those of the Samnite and Roman patricians. The problem of space brought about the transformation of the old indivisible patrician house into small houses, alternating with small shops; it led also to habitation on the upper floor, reached by means of wooden staircases, lighted by open balconies, and divided up by light wooden-frame partitions. Examples of such crowding are the House of the Vestals, the House of the Anchor, the House of the Dioscuri, the House of the Citharist. On the other hand there are houses which reflect the taste of cultured Pompeian society, such as the House of the Menander, the House of the Lovers, the House of the Epeubus (which takes its name from a

EDWIN SMITH

fine bronze statue converted into a lampstand, found in 1925), the House of Loreius Tiburtinus (or of D. Octavius Quartio), the House-Villa of Julia Felix, with a bath for public use, installed by the owner-tenant, announced by a notice affixed to the entrance.

Finally, there are modest middle-class houses, such as the House of Amandio, the House of the Priest Amandus, and the House of the Moralist, and working-class houses. Visitors to Pompeii for reasons of trade found accommodation in the *hospitia* (inns), situated at various points of the city, usually near the gates.

Painting, Mosaic, Sculpture, and Minor Arts.—Pompeii, together with Herculaneum and Stabiae, has preserved the richest evidence extant of ancient painting, used extensively in the decoration of houses and villas, evidence the more precious because the Greek painting which inspired the Campanian is virtually lost.

The wall decoration of Pompeii, from the mid-2nd century B.C. to the day of the eruption, is conventionally divided into four styles:

1. First (incrustation) style (180–80 B.C.), in which the stucco decoration imitates in various colours the plaster or marble facing of the walls (House of Sallust, House of the Faun).

2. Second (architectural) style (80 B.C.–A.D. 14), in which the decoration by the use of perspective creates the illusion of an architectural composition two or more planes in depth; figured compositions appear in the large pictures of mythological, heroic, or religious subjects as well as in the smaller pictures inserted as panels between the architectonic features (House of the Silver Wedding, House of the Cryptoporticus, Villa of the Mysteries).

3. Third (ornamental and Egyptianizing) style (c. A.D. 14–62), in which the architectural wall schemes are flat and assume a chiefly

EDWIN SMITH

THE TEMPLE OF APOLLO WITH MT. VESUVIUS IN THE BACKGROUND

ornamental character; columns, bands, and friezes are enriched with decorative minutiae treated with extreme delicacy and skill; the central painting dominates the decorative composition (House of L. Caecilius Jucundus, House of Spurius Mesor, House of M. Lucretius Fronto).

4. Fourth (illusionist) style (c. A.D. 62-79), in which the whole wall is a purely ornamental composition without any sharp distinction between the architectural elements and the subject portrayed; the architecture, although linked with the second style, is of fantastic design, overburdened with ornamental motifs, while the figured paintings are true decorative panels, often painted separately (House of the Vettii).

Paintings of popular subjects, such as paintings and posters on shops, portrayals of scenes in hostleries or workshops, pictures of religious ceremonies and *lararia*, fall outside this classification.

In the houses of the rich, mosaic decoration is never lacking, and it is found in more modest forms in even the humblest dwellings in a wide range of types from *opus signinum*, in terra-cotta fragments, passing on to *lithostraton*, consisting of white pebbles interspersed with coloured stones, to true mosaic in white, black, and polychrome tesserae, with a rich variety of geometrical designs, often of scenes drawn from mythology or from nature. (See also MOSAIC.) The mosaic of the Battle of Issus, found in the House of the Faun and now in the Museo Nazionale at Naples, is of great artistic value, being a copy of a lost Hellenistic painting (see GREEK ART: *The Hellenistic Period* [c. 330-c. 30 B.C.]: *Hellenistic Painting*). Other mosaics of particular artistic value are those discovered in the so-called Villa of Cicero (in the Naples museum) of scenes and sketches of life of the people in Hellenistic settings; one of these bears the signature of Dioscurides of Samos. In the Flavian era mosaic is replaced by floors in inlay or *opus sectile*.

Pompeii has also yielded a valuable range of bronze and marble sculptures, besides gold, silver, bronze, terra-cotta, glass, bone and ivory household objects of every type; the most precious works

of art are mostly imported items, but there are also many articles of local workmanship. Among the more important sculptures, which testify to the eclectic taste of the ancients in art, are the "Apollo Citharoedus" from the House of the Citharist; the "Ephebus" from the House of P. Cornelius Tages; a copy of the "Doryphoros" of Polyclitus which was in the *palaestra*; the "Ephebus" of the Polyclitan school found outside Porta Vesuvio; and a copy of Lysippus' "Heracles Epitrapezius" discovered in the coastal district. But most significant for the art and civilization of Pompeii are the many bronze statuettes which ornamented the fountains, the nymphaea, the gardens, and the triclinia; the "Dancing Faun" from the House of the Faun, the "Satyr with the Wineskin" from the House of the Centenary, the "Drunken Silenus" from the House of the Marbles, the so-called "Narcissus," and so forth. Most of the statues, including the busts and some excellent imperial portraits, are preserved in the Museo Nazionale, Naples: the busts of Gaius Norbanus Sorex and the banker Lucius Caecilius Jucundus are among the most vigorous examples of Roman art.

Toilet and table articles display special richness and taste. These include two splendid silver services from a suburban villa at Boscoreale (mostly in the Louvre, Paris) and from the House of the Menander (discovered 1930; in Naples); the blue cameo glass vase, found in a tomb near Porta Ercolano, also at Naples; and finally the jewelry, which without attaining the delicacy of Greek and Etruscan craftsmanship gives a clear picture of women's tastes in Pompeii.

The finds of ordinary objects such as tools and food, and the abundance on the walls of graffiti of every kind, from lines of Virgil and electioneering notices to the crudest obscenities, give a vivid impression of the life of the city. Its destruction and rediscovery have inspired, e.g., Bulwer-Lytton's *The Last Days of Pompeii* (1834), Leopardi's poem "La Ginestra" (1836), and Théophile Gautier's *Arria Marcella* (1852); more recent works include Jack Lindsay's *The Writing on the Wall* (1960).

POMPEIUS (frequently anglicized as POMPEY), the name of a plebeian Roman family with three different branches, which may have come from Picenum, where it was influential and owned property; it was "noble" since 141 B.C., the year in which for the first time one of its members, a Quintus Pompeius, was consul.

GNAEUS POMPEIUS STRABO (d. 87 B.C.) was a skilful general who as consul in 89 campaigned successfully in the Social War (the war of the Italian *socii*, "allies"), captured Asculum, and celebrated a triumph; he carried the law (*lex Pompeia*) granting Latin status to the inhabitants of Cisalpine Gaul north of the Po River, which may have been the charter by which Cisalpine Gaul was constituted a province. He evaded an attempted prosecution for treason (*maiestas*) and retained command of his army in 88 in Picenum after it had murdered the consul Quintus Pompeius Rufus who was sent to supersede him. Though in 87 he obeyed the Senate's summons to come with his army to defend Rome against the attack of Cinna and Marius, he declined at the critical point to drive home his military advantage. He was perhaps intriguing with Cinna in the hope of using his army to secure dominant power for himself; but in an epidemic which killed large numbers of his troops he died. He was described by Cicero in 65 B.C. as "a man hated by the gods and the nobility."

GNAEUS POMPEIUS MAGNUS (POMPEY THE GREAT) (106-48 B.C.), son of the preceding, an exact contemporary of Cicero, cele-

brated a triumph and commanded armies before he was even a member of the Roman Senate, conquered Mithradates VI of Pontus, and was generally esteemed the greatest general and administrator of the late Roman Republic until his defeat by Julius Caesar at Pharsalus in 48. He served under his father in the Social War; joined, then in 84 abandoned, the popular cause of Cinna; raised three legions from clients and veterans of his father in Picenum to fight for Sulla on his return to Italy in 83. He married Sulla's stepdaughter Aemilia and in '81 and 80 recovered Sicily and Africa for Sulla. In Africa his army saluted him, perhaps not as *imperator* but as *Magnus* ("great"), by which name—no doubt because of his supposed likeness to Alexander the Great—he was probably called already in his camp. Sulla addressed him by this name on his return to Italy, after being forced to tolerate Pompey's refusal to disband his army in Africa. It was more like a Hellenistic royal

MARBLE HEAD (c. 60-50 B.C.) OF POMPEY THE TRIUMVIR: IN THE NY CARLSBERG GLYPOTEK, COPENHAGEN

name than a Roman one, and had something in common with Sulla's name of *Felix*; it embarrassed Pompey for some years after Sulla's death.

He celebrated a triumph on March 12, 79. After the death of Sulla, with whom at the end he was not on good terms, he received extraordinary military commissions from the Senate to help in suppressing the risings of Lepidus in Italy in 78/77—this was when he broke his word and executed the father of M. Brutus, the later assassin of Julius Caesar—and of Sertorius in Spain (77-71). In Italy he defeated the remnants of Spartacus' army on his return in 71, was elected consul for 70 with strong popular

support (though he was not even a senator nor of the proper age), and triumphed on the last day of the year. Crassus was his colleague as consul; their relations, ever since Sulla had shown his preference for Pompey, were consistently bad.

From 70 until his return from the east in 62 he had strong popular and equestrian support (see *EQUITES*) and was suspected and feared as a possible subverter of republicanism by the conservative element in the Senate, the Optimates, particularly Q. Lutatius Catulus (consul of 78). The most unpopular of Sulla's constitutional changes were revoked in his consulship; in 67 by the *lex Gabinia* he received a three-year commission (which he executed in three months) to eliminate piracy from the Mediterranean, and in 66 by the *lex Manilia* he was given command in the war against Mithradates in which Lucullus (*q.v.*) had recently been superseded. Mithradates was defeated at Nicopolis (modern Nik in northeastern Turkey), and driven to the Crimea, where he died in 63; his son-in-law Tigranes I of Armenia submitted to Pompey. Pompey proceeded, with ostentatious disregard of arrangements made previously by Lucullus and the senatorial commission sent out to assist Lucullus, to make far-reaching administrative arrangements affecting the whole area of his conquests. The province of Cilicia was enlarged; two new provinces, Bithynia-Pontus and Syria, received charters (the *lex Pompeia*, the constitution of Bithynia, was still effective in the 2nd century A.D.); and in Palestine he deposed King Aristobulus and appointed Hyrcanus high priest and ethnarch of Galilee, Judaea, and Peraea. On returning to Italy in late 62, he disbanded his army at Brundisium (instead of repeating Sulla's march on Rome, as alarmist Optimates had anticipated), and celebrated his third prodigious triumph on Sept. 28/29, 61.

In politics from 61 to 50 he showed neither courage, determination, nor policy. Never having served the apprenticeship of a junior senator, he did not feel at home in politics or with politicians. His guarded and ambiguous utterances were susceptible to, and received, the most varied and often sinister interpretations. Like Cicero, he was isolated; accepted wholeheartedly by neither

Populares nor Optimates (among whom he had offended the Metelli and their connections by his divorce in 62 of his third wife Mucia, mother of his two sons and of his daughter). Only his administrative genius remained unimpaired until his serious illness in early summer 50.

Understandably piqued by Pompey's refusal to countenance a senatorial debate on his eastern settlement, the Senate delayed making land allotments to Pompey's troops. His acts were in the end confirmed and land allotments made through bills promoted by Caesar as consul in 59, the outcome of the pact (which modern historians conventionally call "the first triumvirate") by which Pompey, Crassus, and Caesar joined forces in politics for their separate purposes in 60, Pompey marrying Caesar's daughter Julia (very happily, as it transpired) in 59 (see *CAESAR*, *GAIVS JULIVS*; *CRASSVS*). From 58 to 56, Caesar being in Gaul, Pompey, who had disliked the violence with which Caesar's measures were carried in 59 and for whose alliance Optimate politicians were starting to bid, was frightened and excluded from politics in Caesar's interest and at Crassus' instigation, through the belief, carefully fostered by Clodius (*q.v.*), that his life was threatened. So he did nothing to prevent Cicero's exile in 58, but in 57 he played a large part in securing Cicero's recall, and directly afterward, in September, he received a special commission to reorganize the corn supply of Rome (*cura annonae*). There was opposition in the Senate and, organized by Clodius, outside it, to the suggestion of his being commissioned early in 56 to restore Ptolemy XII Auletes to the throne of Egypt. At Luca in April 56 Pompey, Crassus, and Caesar settled their differences and in 55, the year of the dedication of his splendid theatre, Pompey and Crassus were consuls together for the second time. Pompey was given the governorship of the two provinces of Spain for five years and, perhaps because of the corn commission, was allowed to remain in Italy (outside Rome) and to govern his provinces through deputies (*legati*). His ties with Caesar were broken when Julia died in 54 and Crassus was killed at Carrhae in 53. In the wild disorder which followed the murder of Clodius, Pompey was made sole consul just before the beginning of March 52; later in the year his new father-in-law, Q. Metellus Scipio (see *METELLVS*), became consul with him. He was ruthless in ensuring Milo's condemnation for the murder of Clodius, and passed a number of laws for the enforcement of law and order and to check opportunities of corruption in magisterial administration. (For their bearing on Caesar's position, see *CAESAR*). His Spanish governorship was reconferred for a further five years, and the Optimates were forced, however reluctantly, to rely on him as their only hope of checking the now evident ambitions of Caesar, who was expected back from Gaul in 49. The crisis over Caesar's return developed at the end of 50; and on Dec. 2 the consul Gaius Marcellus hysterically placed a sword in Pompey's hand and called on him to defend the state. Whatever the outcome of victory in the civil war might have been, it seems clear that at this moment, as indeed in the whole period since his return from the East, Pompey was instinctively a constitutionalist, and had no ambition for personal domination of an unconstitutional kind.

Caesar invaded Italy on Jan. 11, 49. Pompey was hampered by sharing his command with the consuls (which fact partly explains the failure of Caesar's attempts to negotiate with him), and by the obstinate refusal of L. Domitius Ahenobarbus to comply with his general strategy for withdrawal of the government and its armed forces through Brundisium to Illyricum. Had he pressed his advantage, he would have defeated Caesar when Caesar tried to blockade him at Dyrrhachium in spring 48; he withdrew to the east, and at Pharsalus in Thessaly he was persuaded against his better judgment to engage, and was defeated on Aug. 9. He fled from the battlefield to his wife Cornelia in Lesbos; then to Egypt, where on Sept. 28 he was murdered on landing.

When in his *De republica* (54-52 B.C.) Cicero (*q.v.*) made provision for a "moderator" in his ideal republic, he was not unmindful of Pompey, disappointed though he was at all stages of his career at the failure of his personal hopes for effective political cooperation with Pompey. Pompey's career, indeed, provided Augustus with a number of convenient republican precedents for

the new constitution of the principate, in particular Pompey's position in 52, when he was consul in Rome and governor (*proconsul*) of the Spains, which he administered through *legati*. In the lost books of his *History* Livy wrote so sympathetically of Pompey that Augustus jokingly called him a Pompeian. For portrait see article ROMAN HISTORY.

GNAEUS POMPEIUS MAGNUS (c. 76–45 B.C.), the elder son of Pompey the Great and of Mucia. In 49/48 B.C. during the civil war he commanded the Egyptian section of his father's fleet in the Adriatic. After the Battle of Pharsalus he set out for Africa with the remainder of the Pompeian party but, meeting with little success, crossed over to Spain. He collected an army of 13 legions, which was increased by the Pompeians (including his brother Sextus) who fled from Africa after the Battle of Thapsus (46). Caesar, who regarded him as a formidable opponent, set out against him in person. At Munda (*q.v.*) on March 17, 45, the Pompeians were defeated. Gnaeus escaped, but was soon (early April) captured and put to death.

SEXTUS POMPEIUS MAGNUS (who in the end called himself MAGNUS POMPEIUS PIUS) (?66–35 B.C.), the younger son of Pompey the Great and of Mucia. After his father's death he continued the struggle first against Caesar, then against Octavian (later the emperor Augustus) and Antonius (Mark Antony). From Cyprus, where he had taken refuge, he made his way to Africa and, after the defeat of the Pompeians at Thapsus (46), crossed over to Spain. After Caesar's victory at Munda (45), he abandoned Corduba (Córdoba), though for a time he held his ground in the south, and defeated Asinius Pollio, the governor of the province. After Caesar's murder he came to terms with Antony and the Senate, but in 43 he was proscribed by the triumvirate and put himself at the head of a fleet manned chiefly by slaves or proscribed persons, with which he made himself master of Sicily, and from there ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him at Misenum (39), which was to leave him in possession of Sicily, Sardinia, and Achaëa, provided that he would allow Italy to be freely supplied with corn. But the arrangement could not be carried into effect, as Sextus renewed the war and gained some considerable success at sea. In 36, however, his fleet was defeated and destroyed by Agrippa at Naulochus off the north coast of Sicily. After his defeat he fled to Mytilene, and from there to Asia Minor. In an attempt to make his way to Armenia he was taken prisoner by Antony's troops and put to death at Miletus.

POMPONAZZI, PIETRO (1462–1525), Italian philosopher and a leading representative of Renaissance Aristotelianism as it had developed at the Italian universities (*i.e.*, in conjunction with medicine rather than with theology) after the end of the 13th century. He was born in Mantua on Sept. 16, 1462, studied philosophy and medicine at Padua and taught philosophy in that university (1487–1509, with interruptions), at Ferrara, and finally at Bologna (1512–25), where he died on May 18, 1525. Pomponazzi was thoroughly versed in Aristotle and his commentators, especially Averroës and St. Thomas Aquinas. His questions and lectures on Aristotle are still for the most part unpublished. His treatise on the immortality of the soul, *De immortalitate animae* (1516), was violently attacked but not officially condemned, and the author was allowed to defend his position in his *Apologia* (1518) and *Defensorium* (1519). He contended that the immortality of the individual soul cannot be demonstrated on the basis of Aristotle or of reason but must be accepted as an article of faith. In developing this view, he maintains that the end of human life consists in moral action and that virtue is its own reward, vice its own punishment. This moral virtue constitutes the peculiar dignity of man. Pomponazzi's largest treatises, *De incantationibus* and *De fato*, were published posthumously (1556 and 1567). The former proposes a natural explanation of several reputedly miraculous phenomena. The latter defends the Stoic doctrine of fate against Alexander of Aphrodisias and adds a subtle philosophical discussion of predestination and free will.

PONCA CITY, a city of Kay County, Okla., U.S., 90 mi. NE of Oklahoma City. It was established in 1893. Prior to the opening of the historic Cherokee strip on Sept. 16 of that year (see OKLAHOMA: History), 2,300 \$2 certificates were sold by a private group, entitling each holder to participate in forming the new town and in acquiring a lot. More than 2,000 people gathered at the proposed site, and on Sept. 21 the drawing for lots was held and a provisional government was organized by popular assembly.

The name is from the Ponca tribe of Indians, moved in 1879 to a reservation located south of the townsite. Although the name Ponca City had always been in popular use, the post-office name was Ponca until 1913. The city has a council-manager form of government, in effect since 1954.

Ponca City is an important petroleum centre; two large refineries have a combined daily capacity of more than 100,000 bbl. There is also an annual production of 75,000,000 lb. of carbon black. Other industries in the city process agricultural products; manufacture clothing, oil-drilling bits, farm equipment, ceramics, decorative wreaths and vacuum cleaners; and service diesel engines.

The city is the home of the famous "Pioneer Woman" statue and Pioneer Woman State Park, presented to the people of Oklahoma by Gov. E. W. Marland, and is the location of the Pioneer Woman Historical Museum.

For comparative population figures see table in OKLAHOMA: Population.

(GE. H. S.)

PONCE, the largest and most important city on the southern coast of Puerto Rico and the second city in size and importance on the island. In 1960 the population of the city was 114,286. Ponce's official history dates from 1692 when a town council was established and a mayor appointed. In 1877, because of its growth and importance, the Spanish government elevated Ponce to the category of a city.

The warm, dry climate on the south coast is most agreeable. The average annual temperature is 79° F (26.1° C), and the yearly rainfall is 36 in. Constant breezes coming off the mountains and from the Caribbean Sea assure comfortable living. As Puerto Rico's principal shipping port on the Caribbean, Ponce trades with

the islands of the Lesser Antilles, Colombia and Venezuela. Extensive improvements of the excellent harbour were made under the direction of U.S. agencies. Cement, iron, shoes, candy, textiles, and paper products are some of the more important industrial goods manufactured in Ponce. To the west on the coast is located a large oil refinery. To the east well-irrigated plains produce high-grade sugarcane. Five banking firms have offices in Ponce. There are four radio stations, two television stations, and one daily newspaper.

Excellent highways connect the city with other coastal towns, and two well-kept paved roads lead up over the mountains to the interior and the north coast. The city is also connected with San Juan (q.v.) by regular commercial air service. Ponce's parks, plazas, public buildings, and private residences are well-kept and attractive. In addition to first-class hotels, the city has an ultra-modern tourist hotel.

The Roman Catholic Church maintains the University of Santa Maria with facilities for over 3,000 students in the city.

(T. G. Ms.)

PONCE DE LEÓN, JUAN (1460–1521), Spanish explorer and discoverer of Florida, was born in Tierra de Campos (Palencia), Spain, in 1460. After service in the Moorish wars, he reached the New World with Columbus in 1493. From 1508 to 1509 he explored and settled Puerto Rico. Royal orders to search for new lands and a belief in the legend of a Fountain of Youth on Bimini Island in the Bahamas led Ponce de León to the discovery of Florida at Easter time in 1513. The region was named "Florida" from the name of the day in the calendar. Landing near the site of modern St. Augustine, he coasted southward, sailed through the Keys called "The Martyrs," and ended his search near Charlotte Harbor. Though named in 1514 governor to colonize Bimini and Florida, Ponce de León first campaigned against the Carib Indians and occupied Trinidad. Finally, in 1521, he left for Florida with two ships and 200 men, landing near Charlotte Harbor. Unfriendly Indians attacked, mortally wounded him, and ended the venture. He died soon after in Havana.

See also FLORIDA: History.

See the *Florida Historical Quarterly Review*, vol. xiv, pp. 7–66 (1935).

(A. B. T.)

PONCELET, JEAN VICTOR (1788–1867), French mathematician and engineer, one of the founders of modern projective geometry, was born at Metz on July 1, 1788. From 1808 to 1810 he attended the École Polytechnique and afterward, until 1812, the *école d'application* at Metz. He then became lieutenant of engineers and took part in the Russian campaign during which he was taken prisoner and confined at Saratov, on the Volga, until 1814, when he returned to France. During his imprisonment he began his researches on projective geometry which led to his great treatise on that subject. This work, the *Traité des propriétés projectives des figures* (1822; 2nd ed., 2 vol., 1865–66), is occupied with the investigation of the projective properties of figures and entitles Poncelet to rank as one of the greatest of those who took part in the development of the new geometry of which G. Monge was also a founder (see GEOMETRY: Projective Geometry). Poncelet developed the principle of duality and discovered the circular points at infinity. From 1815 to 1825 he was occupied with military engineering at Metz, and from 1825 to 1835 he was professor of mechanics at the *école d'application* there. In 1834 he became a member of the Académie; from 1838 to 1848 he was professor to the faculty of sciences at Paris and from 1848 to 1850 commandant of the École Polytechnique, with the rank of general. He died at Paris on Dec. 22, 1867.

Poncelet's works include *Cours de mécanique, appliquée aux Machines* (1826) and *Mémoire sur les roues hydrauliques à aubes courbes* (1826).

See Eric T. Bell, *Men of Mathematics* (1937); M. Kerker, "Sadi Carnot and the Steam Engine Engineers," *Isis* (Sept. 1960); J. R. Newman (ed.), *The World of Mathematics*, pt. 1, reprint (1962).

(O. Oe.)

PONCHIELLI, AMILCARE (1834–1886), Italian composer best known for his opera *La Gioconda*, was born at Paderno Fasolaro, near Cremona, on Aug. 31, 1834. He studied at Milan

and produced his first opera, *I Promessi Sposi*, based on the novel of Alessandro Manzoni, at Cremona (1856). In a revised version it was frequently given in Italy and abroad. Between 1873 and 1875 he wrote two ballets and four operas and became the most important of Verdi's Italian contemporaries. *La Gioconda* (La Scala, Milan, 1876), on a libretto by Arrigo Boito based on Victor Hugo's *Angelo*, achieved wide success at the end of the 19th century. Later it was chiefly known for its ballet "Dance of the Hours," but returned to the repertory of Italian opera houses in the 1950s. From 1881 to 1886 Ponchielli was musical director at Bergamo Cathedral; there he wrote several sacred works. He died in Milan on Jan. 16, 1886.

See A. Damerini, *A. Ponchielli* (1940).

(Dr. H.)

POND, JOHN (1767–1836), English astronomer who reorganized the Royal Observatory on modern lines, was born in London in 1767. After leaving Trinity College, Cambridge, he traveled abroad, making astronomical observations. He returned to England and settled at Westbury, Somerset, about 1798. There he began to determine star places with a fine altitude and azimuth circle of 2½-ft. diameter. His demonstration of deformation in the Greenwich mural quadrant as a result of age made it necessary to introduce astronomical circles into the equipment at the Royal Observatory, Greenwich. In 1807 he was elected a fellow of the Royal Society and in the same year he married and went to live in London. In 1811 he succeeded Nevil Maskelyne as astronomer royal.

At Pond's instigation the instrumental equipment at Greenwich was completely changed and the number of assistants increased from one to six. The superior accuracy of his determinations was attested by S. C. Chandler's discussion of them in the *Astronomical Journal* (1894). Pond published *Astronomical Observations made at the Royal Observatory* from 1811 to 1835, translated P. S. Laplace's *Système du monde* (2 volumes, 1809), and contributed 31 papers to scientific collections. His catalogue of 1,112 stars (1833) was of great value, and he received many academic honours. Pond retired in 1835 and died at Blackheath, Kent, on Sept. 7, 1836.

PONDICHERRY (French PONDICHÉRY from Tamil *puddu cheri*, "new village"), the name of a centrally administered state of India and of its capital, and of the chief settlement of former French India. On Nov. 1, 1954, on the basis of a vote of the elected representatives of French Indian municipalities, the administration of French India was transferred to the Republic of India; central control was initiated through a chief commissioner with headquarters at Pondicherry; and on Jan. 6, 1955, the four settlements together were designated the state of Pondicherry. A treaty for the *de jure* transfer was signed on May 28, 1956, and ratified in July 1962. (For early history of French India, see INDIA, FRENCH.)

The state thus comprises: the town and settlement of Pondicherry on the Coromandel Coast (q.v.) and geographically in the South Arcot district of Madras; Karikal (q.v.), an enclave in the Thanjavur (Tanjore) district of Madras; Mahé (q.v.) on the Malabar Coast in the Cannanore district of Kerala; and Yanam in the East Godavari district of Andhra Pradesh. Area 185 sq.mi. (479 sq.km.); pop. (1961) 369,079.

There are three colleges, including one for medicine, a teacher's training centre, an arts and crafts school, a research institute, and a general educational institute, all in Pondicherry town. The chief food crops of the territories are paddy and a variety of millet; cash crops include peanuts, coconuts, cotton, tobacco and chillies. There are a number of textile mills and oil presses in Pondicherry town and toymaking and handmade matches are some of the cottage industries. The various units of the state are well served by road or rail.

PONDICHERRY TOWN lies 122 mi. (196 km.) SSW of Madras City by rail. Pop. (1961) 40,421. A canal divides it into two parts, Ville Blanche and Ville Noire. All the main streets, running parallel to one another, lead to the open roadstead off the shore. The

port of Pondicherry has no harbour, and ships have to lie a mile or two off, but its roadstead was once considered to be the best on the Coromandel Coast. There is an old screw-pile pier in the centre of the port which serves both as a promenade and a landing place for cargo. In the 1960s a new pier was constructed. The statue of Joseph François Dupleix, governor general from 1742 to 1754, faces the shore end of the pier.

The town is the seat of a *préfecture apostolique* and of the Missions Etrangères, successors of the Mission du Carnatic, founded by the Jesuits in 1776. It is also the centre of the well-known *ashram* (community) founded by Sri Aurobindo (*q.v.*). In and around the town are artesian wells that supply a large quantity of water for irrigation, the chief local crops being paddy and peanuts.

The site of Pondicherry was purchased in 1674 by François Martin from the raja of Gingee, but the first permanent settlement was made there in 1683. In 1693 the Dutch took Pondicherry, but restored it, with the fortifications greatly improved, in 1697, at the Peace of Rijswijk. In 1761 it was taken by Col. Eyre Coote from the comte de Lally. In 1763 it was restored to the French. In 1778 it was again taken, by Sir Hector Munro, and its fortifications destroyed. In 1783 it was retransferred to the French, and in 1793 recaptured by the English. The Treaty of Amiens in 1802 restored it to the French, but it was retaken in 1803. In 1816 it was again restored to the French. (G. Kn.; X.)

PONDOLAND: see TRANSKEI.

PONDWEED, the popular name for the family Potamogetonaceae, a small, taxonomically problematic group of almost exclusively submerged aquatic plants widely distributed around the world but especially abundant in temperate regions. It is regarded

by some as an unnatural "lumping" of several closely related families (e.g., Zannichelliaceae, Zosteraceae, Cymodoceaceae). The largest genus, *Potamogeton*, common in ponds, lakes, and ditches, comprises about 90 species. It includes plants with slender branched stems and submerged and translucent, or floating and opaque, leaves, often with membranous united stipules. The small flowers are borne above the water in axillary or terminal spikes; they have four stamens, which bear at the back four small petallike structures and four free carpels, which ripen to form four

JOHN H. GERARD

LEAVES AND FLOWERS OF A PONDWEED, POTAMOGETON AMERICANUS

small green fleshy fruits, each containing one seed within a hard inner coat. *Zannichellia*, occurring in fresh and brackish ditches and pools in temperate and tropical regions, is known as horned pondweed, from the curved fruit. *Zostera* includes the saltwater eelgrass, or grass wrack, of marine coasts. These genera and the few others grouped in the family are of some importance in conservation as sources of food for wildfowl and shelter for fish.

PONGEE, a plainwoven fabric made of tussah or wild silk, originated in China. The name is believed to have been derived from the Chinese *pun-chi*, meaning home woven, or possibly from *pun-shih*, native or wild silk. It is woven in widths from 18 to 40 in. or more; it may be plain or printed, natural or dyed.

Shantung originally was a rough-textured pongee made in the province of Shantung, China. The term now covers a broad class of plain-weave, slub-yarn fabrics having the general texture of the original but woven either of silk or any of the man-made fibres. It is dyed or printed and is a popular fabric for women's dresses and suits. (G. R. Co.)

PONIATOWSKI, a great Polish family, with princely rank from 1764. Jan Ciolek (d. c. 1676), having inherited the property of Poniatow, took the name Poniatowski and founded the family, which settled in the district of Cracow.

STANISLAW PONIATOWSKI (1676–1762), Jan's grandson, was born on Sept. 15, 1676. After serving with his brother Jozef as a

volunteer in the Austrian Army against the Turks, under the command of Gen. Michal Sapieha, he accompanied Sapieha to Lithuania in 1697 and settled there. During the Northern War (*q.v.*), together with the Sapiehas, he sided with the Swedes. Major general in the army of Charles XII of Sweden, he rendered great services to Stanislaw Leszczynski (STANISLAW I, *q.v.*), but after Charles XII's death he was reconciled with Augustus II of Poland. Married in 1720 to Princess Konstancja Czartoryska, he joined his two brothers-in-law in the leadership of the Familia, a court party. He was appointed grand treasurer of Lithuania in 1722 and palatine (*wojewoda*) of Mazovia in 1731. From 1728 he was commander in chief of the Polish Army. Despite these favours, during the interregnum of 1733 the Familia supported Leszczynski, hoping that after his death they would take possession of the throne; but when Augustus began to reign the Familia returned to the role of a court party. In 1752 Stanislaw received the highest dignity in the Senate, that of castellan of Cracow. A partisan of constitutional reforms, he expounded his program in the *List Ziemianina* ("Letter of a Country Squire"; 1744). He died on Aug. 3, 1762, at Ryki.

Stanislaw's second son, STANISLAW AUGUST, became king of Poland as Stanislaw II (*q.v.*) in 1764; and during the coronation session of the *sejm* the new king's brothers, Kazimierz, Andrzej, and Michal (see below), received princely titles.

KAZIMIERZ (1721–1800), from 1742 grand chamberlain of Poland, commanded the Familia's private army against the "republican" followers of Jan Branicki (his brother-in-law) in the little war of the interregnum of 1763–64. He was a close adviser to Stanislaw II at the beginning of his reign, trying to curb the influence of his Czartoryski uncles and to bring about a rapprochement between Poland, Austria, and France against the policy of the Russian empress Catherine II. After the first partition of Poland (1772) he withdrew from political life.

ANDRZEJ (1734–1773) as a young man served in the Austrian Army and during the Seven Years' War was promoted lieutenant general in 1760. He was married to the countess Teresa Kinsky. In the years 1765–66 he was engaged in official and secret missions to Vienna, with a view to a marriage between King Stanislaw II and an Austrian archduchess. From Austria he finally received the title of prince (in the Kingdom of Bohemia).

MICHAL (1736–1794) was from 1773 bishop of Plock and from 1784 archbishop of Gniezno and primate of Poland. After the first partition of Poland he became one of the closest political advisers of King Stanislaw II. From 1776 he headed the Commission of National Education. In favour of submissiveness toward Russia, he opposed the alliance with Prussia (1790).

JOZEF ANTONI (1763–1813), Polish general and marshal of France, was born in Vienna on May 7, 1763, the son of Andrzej. He served in the Austrian Army, but in 1789, at the request of his uncle, King Stanislaw II, he was transferred to the Polish Army. Appointed lieutenant general, he fought the Russian invaders in 1792. When the king acceded to the Confederation of Targowica (see POLAND: History) he threw up his commission and went to Vienna. In 1794 he joined the insurrection led by Tadeusz Kosciuszko. After the third partition (1795) he lived in Warsaw in retirement. During the Napoleonic Wars (*q.v.*), when the Prussians left Warsaw in 1806, he became commander of the Polish National Guard. Adhering to Napoleon, he was appointed minister of war of the Duchy of Warsaw in 1807. Two years later he led the Polish Army against the Austrians, defeating them at Raszyn (April 19, 1809). In Napoleon's campaign of 1812 against Russia he commanded the V (Polish) Army Corps, distinguishing himself at Smolensk and at Mohaisk. After the retreat from Moscow he remained faithful to Napoleon and formed a new Polish Army Corps, with which he contributed to the victory at Lützen (May 2, 1813). A marshal of France from Oct. 16, 1813, he fought brilliantly at Leipzig; but on Oct. 19, having been five times wounded, he perished in the Elster River when trying to swim it on horseback. He is buried in the Wawel Cathedral in Cracow.

STANISLAW (1754–1833) was the son of Kazimierz. Grand treasurer of Lithuania from 1784, he was Stanislaw II's candidate for the succession to the Polish crown. After the destruction of

Poland in 1795 he settled in Vienna, but later moved to Rome and then to Florence. By a marriage with Cassandra Luci he had two sons, Charles (1811–87) and Joseph (*see below*), who obtained the Tuscan title of Principi di Monte Rotondo in 1847 and the Austrian princely title of Poniatowski in 1850.

JOSEPH (1816–1873), born in Rome on Feb. 20, 1816, was the envoy of Tuscany in London (1849) and in Paris (1853). He also composed many operas, produced in Florence, Paris, and London. A friend of Napoleon III, he became senator of the French Empire in 1855. Having accompanied Napoleon to England in 1871, he died in London on July 3, 1873.

Joseph's son STANISLAS (1835–1908), who had been equerry to Napoleon III, left a son ANDRÉ (1864–1954), who prospered in business and finance and described his eventful life in *D'un siècle à l'autre* (1948). This André's sons STANISLAS (1895–), CASIMIR (1897–), and ANDRÉ (1899–) served during World War I in the French and later in the Polish army. MARIE ANDRÉ (1921–1945), son of the last-named André, served in World War II in the Polish Army from 1940 and was killed in the Netherlands.

See S. Mnémon, *L'Origine des Poniatowski* (1913); S. Askenazy, *Fürst Joseph Poniatowski* (1912). (EM. R.)

PONSARD, FRANÇOIS (1814–1867), French dramatist who, with Émile Augier, advocated a return to a moral and socially conscious literature after the extravagances of Romanticism, and so represents the *École du bon sens*. He was born on June 1, 1814, at Vienne (Isère) and studied law. After translating Byron's *Manfred* (1837), he wrote *Lucrèce*, performed in 1843, the year in which the failure of Hugo's *Les Burgraves* marked the end of Romantic triumphs in the French theatre. *Lucrèce* was classical in style as well as subject, though not entirely uninfluenced, technically, by Romantic innovations. Notable among Ponsard's later plays were *Agnès de Méranie* (1846), *Charlotte Corday* (1850), *L'Honneur et l'argent* (1853), *Le Lion amoureux* (1866), and *Galilée* (1867), which aroused considerable clerical opposition. Ponsard was elected to the Académie Française in 1855, and was highly regarded by Napoleon III. He died in Paris on July 7, 1867.

See *Œuvres complètes* (1865–76); C. Latreille, *La Fin du théâtre romantique et F. Ponsard* (1899). (W. D. HH.)

PONSONBY, the name of an English family, seated at Ponsonby and elsewhere in Cumberland since before the 13th century, a branch of which has been connected with Ireland since 1649. Honours held by the family have been the baronies of Bessborough, County Kilkenny (from 1721), of Ponsonby of Sysonby in Leicestershire (from 1749), of Ponsonby of Imokilly, County Cork (1806 66), and of de Mauley of Canford in Dorsetshire (from 1838); the viscountcies of Duncannon of Fort Duncannon, County Wexford (from 1723), and of Ponsonby of Imokilly (1839–55); and the earldom of Bessborough (from 1739).

The family's Irish connection began when JOHN PONSONBY (1608–1678) of Hale in Cumberland, who raised a regiment of horse and fought for Oliver Cromwell in Ireland in 1649, was given Kildalton Castle, which he renamed Bessborough after his second wife Elizabeth. His numerous descendants by his first marriage remained in Cumberland, many later emigrating to Tasmania. His eldest son by his second marriage, WILLIAM (1659–1724), held Londonderry against James II (1689–90). He was created Baron Bessborough in 1721 and Viscount Duncannon in 1723. His eldest son, BRABAZON (1679–1758), was created earl of Bessborough in 1739 and Baron Ponsonby of Sysonby (peerage of Great Britain) in 1749.

Brabazon's third son, JOHN (1713–1787), was speaker of the Irish House of Commons from 1756 to 1771. One of his sons, WILLIAM (1744–1806), was created Baron Ponsonby of Imokilly in 1806; another, GEORGE (1755–1817), was lord chancellor of Ireland. William's son JOHN (1771–1855), created Viscount Ponsonby in 1839, was ambassador to Constantinople (1832–41) and to Vienna (1846–50). On his death without issue the viscountcy became extinct and the barony passed to his nephew WILLIAM (1816–1861), son of his brother WILLIAM (1782–1815), the major general who served in the Peninsular War and fell at Waterloo. The barony became extinct on the death of WILLIAM BRABAZON

(1807–1866), cousin and successor of the 3rd baron.

JOHN WILLIAM (1781–1847), 4th earl of Bessborough, was home secretary in the first ministry (1834) of Viscount Melbourne, the husband of his sister CAROLINE (1785–1828). His brother, WILLIAM FRANCIS SPENCER PONSONBY (1787–1855), married the heiress of the barony of De Mauley and was created Baron de Mauley in 1838. His great-grandson HUBERT WILLIAM PONSONBY (1878–) is 5th baron. A nephew of the 4th earl, SIR HENRY PONSONBY (1825–1895), was Queen Victoria's private secretary from 1870 until his death.

The 10th earl of Bessborough is FREDERICK EDWARD NEUFELZE PONSONBY (1913–).

See Sir John Ponsonby, *The Ponsonby Family* (1929).

(E. A. MACL.)

PONTA DELGADA, the capital of an administrative district comprising the islands of São Miguel and Santa Maria in the Portuguese archipelago of the Azores. Pop. (1960) 22,740. Ponta Delgada is on the south coast of São Miguel, in 37° 45' N and 25° 40' W. Its mild climate and the fine scenery of its mountain background render it attractive to visitors; it is the most populous town and the most important commercial centre of the archipelago. The harbour has a breakwater 4,900 ft. (1,500 m.) long. Fueling, supply, and minor repair facilities are available for ships. A local shipping line maintains regular commercial services with Portugal, northern Europe, and the United States. (J. Ao.)

PONTA GROSSA, a city in the central portion of the state of Paraná, Braz. It is connected by highway and rail with the state capital, Curitiba, and is a station on the north-south railroad that connects Porto Alegre and São Paulo. Pop. (1960) 77,803. Ponta Grossa is a major distribution centre of western Paraná, a region that produces maté (Brazilian tea), cereals, tobacco, rice, and livestock. The city also has a lumber industry. A settlement of Russians, Poles, and Germans, established there about 1898, has prospered. Ponta Grossa began as a supply town on the old colonial cattle trail from the state of Rio Grande do Sul to São Paulo. (J. J. J.)

PONTANO, GIOVANNI (JOVIANUS PONTANUS) (1422 or 1426–1503), Italian humanist whose voluminous and wide-ranging work illustrates the diversity of the Renaissance scene, was born at Cerreto, in Umbria, on May 7, 1422 or 1426. At about the age of 21 he went to Naples, where he spent the rest of his life. In 1471, on the death of the scholar Antonio Beccadelli (Panormita), he became head of the Neapolitan humanist academy, called after him Accademia Pontaniana. In 1461 he married Adriana Sassone, who bore him one son and three daughters and died in 1490. From 1486 until 1495 he was the effective political leader of the kingdom of Naples as adviser, military secretary and chancellor to the kings of the Aragonese dynasty. He died in September 1503.

Pontano's extensive literary output, all in Latin, includes a historical work (*De bello Neapolitano*), philosophical treatises (*De prudentia*, *De fortuna*), an astrological poem (*Urania*), five dialogues dealing with such widely differing subjects as morals and religion, philology and literature (*Aegidius*, *Actius*, *Asinus*, *Antonius*, *Charon*) and many lyrics on love, nature, family life and scenes from Neapolitan life (*Lepidina*, *Amorum libri*, *Eridanus*, *Hendecasyllabi*, *De amore coniugali*, *Jambici*, *Tumuli*). His erudition embraced all fields of knowledge, but neither as a thinker nor as a poet did he display a powerful personality. The importance of his work for the cultural and, even more, the social history of the Renaissance, lies not so much in its erotic originality as in the fact that it synthesizes and reproduces, more completely perhaps than that of any other humanist, the diverse elements of the period.

PONTCHARTRAIN, a lake in southern Louisiana, U.S., 40 mi. (64 km.) long and 25 mi. (40 km.) wide, with an area of 625 sq.mi. (1,619 sq.km.) and a mean depth of from 10 to 16 ft. (3 to 5 m.). Lying due north of a bend of the Mississippi, it is in places only 5 mi. (8 km.) distant from the river. More a lagoon than a lake, since it connects eastward with the Gulf of Mexico by a narrow passage called the Rigolets, Pontchartrain is

brackish and teems with game fish. It was discovered by Pierre le Moyne, sieur d'Iberville, in 1699. New Orleans, founded on the Mississippi, now extends to the lake, on which there are a state park and many small resorts. Pontchartrain causeway, a 24-mi. multispan concrete bridge, crosses the lake north from New Orleans.

(W. A. Ro.)

PONTE, JACOPO DA: see BASSANO, JACOPO DA.

PONTEFRACT, a market town and municipal borough in the West Riding of Yorkshire, Eng., 25 mi. (40 km.) SSW of York and 13 mi. (21 km.) SE of Leeds by road; it is served by three railway stations. Pop. (1961) 27,128. An ancient Brigantian settlement existed there, to be succeeded by the Saxon town of Kirkby; the name was changed to Pontefract at some date prior to 1140, when the death in the town of Archbishop Thurstan was recorded. The building of the famous castle was begun in 1069 by Ilbert de Lacy. In the 14th century the much-altered castle and manor passed by marriage to Thomas, earl of Lancaster. Henry IV held his court there for many years after deposing Richard II, and within the castle dungeons Richard was imprisoned until his death in 1400. There too, after the Battle of Agincourt (1415), Charles, duke of Orléans, was imprisoned for more than 20 years. In 1541 Henry VIII made a visit to the north with the object of pacifying the northern counties after the disturbances occasioned by the Pilgrimage of Grace, in the course of which the castle had been taken by Robert Aske, leader of the Pilgrimage, in 1536. Elizabeth I also visited the castle and repaired the chapel, the remains of which can still be seen within the walls. During the Civil War the castle sustained three sieges. It was the last Royalist stronghold to be reduced by Cromwell, who had it dismantled. Sufficient of its walls, towers, and dungeons still remain to give some idea of its former grandeur.

The town was the site of several important monastic settlements, including the priory of St. John, which was later demolished upon the orders of Henry VIII. The material recovered from the demolition was used for the building, about half a mile away, of the New Hall, itself reduced to ruins (which may still be seen) during the Civil War. In Southgate is an ancient hermitage and oratory cut from the solid rock and dating from 1368. The Butter Cross in the market place was erected in 1734 by the widow of the Spaniard Solomon Dupier with whose collaboration Gibraltar had been taken by Adm. Sir George Rooke.

The Church of All Saints, under the castle, was probably built in the 13th century. Ruined in the Civil War, it had its central portion repaired and it is still in use. The Church of St. Giles, first mentioned in a charter of Henry I, became the parish church after the ruin of All Saints.

There are several ancient almshouses. The old town hall (18th century) contains the original plaster cast from which was made the panel depicting the death of Lord Nelson, at the foot of the column in Trafalgar Square, London. The King's School, whose foundation was confirmed by Edward VI in 1549, is now housed in modern buildings. Three miles away, at Ackworth, is the well-known Society of Friends School, founded in 1778. Other principal buildings are the market hall, the courthouse, the barracks (containing a military museum), the assembly rooms, and the municipal offices. There is a racecourse in the park.

The principal industries are those of licorice confectionery, nowadays made chiefly from imported licorice (the town being the home of the celebrated "Pomfret cakes," so named from the old but still current pronunciation of Pontefract), coal mining, furniture making, iron founding, tanning, textiles, and engineering. The market rights are exercised under a charter granted by Roger de Lacy in 1194, while the first mayor was appointed pursuant to a charter of Richard III in 1484. From the end of the 13th century to the Reform Act of 1832 Pontefract returned two members to Parliament. In the 1960s the parliamentary constituency of Pontefract, which includes the borough of Castleford and Featherstone urban district, returned one member. The Pontefract Court of Quarter Sessions has an unbroken history from 1640 to the present day, and the town gives its name to a bishop suffragan in the Wakefield diocese.

PONTEVEDRA, capital of the province of the same name,

region of Galicia, northwestern Spain, is situated on the Lerez River at its entry into an inlet, the Ría de Pontevedra, 31 km. (19 mi.) NNE of Vigo by rail. Pop. (1960) 50,483 (mun.). Noteworthy buildings include the Plateresque church of Santa María la Mayor (1520-59), the 14th-century Gothic convents of San Francisco and Santa Clara, the rococo Santuario de la Peregrina (1778-92), and the ruins of the 14th-century convent of Santo Domingo, now an archaeological museum. Pontevedra is on the railway from La Coruña to Vigo and Portugal. Industries include the manufacture of cloth, hats, leather, pottery, fertilizers, timber, and cellulose and there is an active trade in grain, wine, and fruit. Legend says that Pontevedra was founded by a Greek, Teucro, who called it Helenes, but more likely it was of Roman origin, hence its name (*pons vetus*, "old bridge"), from the 11-arch bridge which, with modifications, still exists and spans the Lerez River. Its port and shipyards were important in the Middle Ages and it is probable that Columbus' ship, the "Santa Maria," was built there. It has also been claimed as the birthplace of Columbus.

PONTEVEDRA PROVINCE, smallest of the four Galician provinces, is mountainous, with a coastline deeply indented by the picturesque *rias bajas* of Arosa, Pontevedra, and Vigo. Area 1,729 sq. mi. (4,390 sq. km.). Pop. (1960) 680,229. Granite is widely used in building construction. Numerous traditional fiestas are held throughout the province and contribute, with the scenic beauty and fine beaches, to its attractions for tourists. Cattle, timber, agricultural produce, fish, and shellfish are exported. Vigo (q.v.), with one of the best harbours in Europe, is an important port of call for transatlantic shipping. Other ports are Villagarcía (also a resort) and Marín (with a naval academy). Inland communications are good and all the mountain ranges are crossed by roads. There are airports at Peinador and La Lanzada.

(J. A. F. A.)

PONTIAC (c. 1720-1769), chief of the Ottawa Indians and leader in the "Conspiracy of Pontiac" in colonial America in 1763-64, was born about 1720, probably on the Maumee River, in what is now northwestern Ohio. His father was an Ottawa and his mother an Ojibwa. By 1755 he had become a chief of the Ottawa and a leader of the loose confederacy of the Ottawa, Potawatomi, and Ojibwa. In 1760 he met Maj. Robert Rogers, famed colonial ranger, then on his way to occupy Michilimackinac and other forts surrendered by the French, and agreed to let the English troops pass unmolested on condition that he be treated with respect. Like other Indians he soon realized the difference between French and English rule—that the Indians were no longer welcomed at the forts and that they would ultimately be deprived of their hunting grounds by encroaching English settlements. There was also widespread resentment among the Indians because of the refusal of the English to continue giving them presents. French hunters and traders encouraged Indian disaffection with vague promises of help from France; and in 1762 Pontiac enlisted the support of practically all the Indian tribes from Lake Superior to the lower Mississippi for a joint move to expel the British. He arranged for each tribe to attack the fort nearest to it in May 1763, and then to combine to wipe out the undefended settlements. Pontiac himself decided to capture Detroit, but his carefully laid plans for a surprise attack on May 7 were betrayed to the commanding officer, and he was forced to lay siege to the fort. The Indians were not used to making long sieges and, after a few months, several of the associated tribes made peace. With his own Ottawa Pontiac continued to camp around Detroit until Oct. 30, when, hearing that no aid from the French could be expected, he withdrew to the Maumee River.

Pontiac's larger plan was more successful. Of the 12 fortified posts attacked by the Indians, all but 4 were captured; most of the garrisons were massacred; several relief expeditions were nearly annihilated, and the frontiers were desolated and plundered. An English officer, Col. Henry Bouquet, succeeded in defeating the Indians at Bushy Run when on his way to relieve Forts Pitt and Ligonier, and in 1764 he led a second expedition into Ohio from Pennsylvania and forced the Indian tribes to sue for peace and release their prisoners. Pontiac still hoped to arouse other tribes

to continue the fight, but after another year he saw that the English were the real masters of the situation and, on behalf of the tribes lately banded in his league, he concluded a treaty of peace and amity with Sir William Johnson at Oswego, N.Y., July 25, 1766. Pontiac, laden with gifts from the enemy, returned to his home on the Maumee. He met his death in 1769 at the hands of an Illinois Indian bribed by an English trader to murder him at Cahokia, Ill. (nearly opposite St. Louis). His death occasioned a bitter war among the Indians, and the Illinois group was all but annihilated by his avengers.

Historians are not in full agreement as to Pontiac's role in the famous conspiracy, for the evidence is fragmentary. There is, however, no doubt that he was one of the most remarkable men of the Indian race in American history, possessing a commanding energy and force of mind combined with subtlety, craft, and organizational ability.

BIBLIOGRAPHY.—Francis Parkman, *The Conspiracy of Pontiac*, 2 vol. (1907); H. H. Peckham, *Pontiac and the Indian Uprising* (1947); W. R. Jacobs, *Diplomacy and Indian Gifts* (1950).

PONTIAC, the seat of Oakland County, Mich., U.S., 26 mi. NW of Detroit (*q.v.*) and within the Detroit metropolitan area, is an important automobile-manufacturing city in the midst of a resort region, with hundreds of lakes and numerous public parks. Named for the famous Ottawa chief, Pontiac was settled in 1818 by the Pontiac Company, organized in Detroit; the site was the intersection of the Clinton River and the Saginaw Trail, which formed part of the Indian route from the Straits of Mackinac to northern Ohio. In the 19th century, Pontiac was the shopping centre for a prosperous agricultural area. It was chartered as a city in 1861; in 1877 its population of about 4,000 supported newspapers, banks, mercantile establishments, hotels, and blacksmiths, gunsmiths, mills, foundries, and small factories.

Its river location made available water power essential to the rise of factories. Most important for its future were the wagon and carriage works, which, with the invention of the automobile, turned to production of cars and parts; in the 20th century, Pontiac's economy has depended largely upon the automobile industry. Pontiac has a commission-manager form of government, in effect since 1920. Pontiac State Hospital is located in the city; nearby are the Cranbrook institutions (private schools, museum and art academy) and the Oakland branch of Michigan State University. The population of the city in 1960 was 82,233; for comparative population figures see table in MICHIGAN: *Population*. (E. S. AD.)

PONTIANAK, a port and the capital of West Kalimantan Province (of Borneo), Indonesia, lies on a tongue of land at the junction of the Kapuas and Landak rivers, 14 mi. (23 km.) from the western Borneo coast. Pop. (1961) 150,220, including many Chinese. The town was formerly the capital of the sultanate of Pontianak, founded in 1772 by Abdul Rahman, who gained the support of the Dutch East India Company (*q.v.*) in claiming the area from the sultan of Bantam (Java). Under Abdul Rahman the town of Pontianak became a trading station, and later it was to be the chief gold town of Borneo. The main industry is shipbuilding. A large factory manufactures palm oil for export, and there are also rubber- and sugar-processing concerns. Houses are built on piles to avoid the regular flooding. Large warehouses store goods for transshipment to other parts of Indonesia and abroad.

Products of the surrounding area include copra and palm oil from the coconut palm groves along the coast, and pepper and rubber which are grown to the north of the city. Rice, maize (corn), cassava, tobacco, and sugar are also grown. The hinterland is tropical forest, with swamplands in between, and the whole area is one of great humidity.

PONTIANUS, SAINT (d. after 235), pope from 230 to 235, is said to have been a Roman by birth. He convened the synod that confirmed Demetrius of Alexandria's condemnation of Origen. At the beginning of the persecution under the emperor Maximinus in 235, Pontianus was exiled to Sardinia, together with Hippolytus. There he resigned the papal office, and died in exile some time after, traditionally in consequence of ill treatment. He was

venerated as a martyr, and his feast day is Nov. 19. His epitaph in the cemetery of St. Calixtus was found in 1909.

See E. Caspar, *Geschichte des Papsttums*, vol. i, pp. 43-46 (1930). (D. AR.)

PONTIFEX, literally "bridge-builder," hence originally a Roman priest whose main duty was no doubt to appease the wrath of the Tiber at having a bridge, the very ancient Pons Sublicius, built over him. This was done by the immemorial ceremony of the *Argei* (a name the derivation of which is uncertain), in which once a year, on May 14, puppets representing men in archaic costume were flung into the water off the bridge.

The *pontifices* originally numbered three and were advisers of the king. In republican times their numbers were increased till they reached 16 at the time of Julius Caesar's dictatorship. They formed the chief group of the college of pontiffs (*collegium pontificum*), which also included the *rex sacrorum*, *flamines* (see *FLAMEN*), and vestal virgins (see *VESTA*). At their head was the *pontifex maximus*, the chief priest of Roman religion. Originally on the death of a pontiff his place was filled by co-option, but from some time in the 3rd century B.C. the *pontifex maximus* and from 103 onward all the pontiffs were elected by a minority of the tribes (17 out of 35), the members of the college retaining the right to nominate candidates. Under the empire, the emperor was always *pontifex maximus* until certain Christian emperors refused the post.

The duties of the college included the performance of sundry rites, not always in Rome itself; if any change in the existing regulations was thought advisable, it was up to the government of the day to take the necessary steps: the pontiffs themselves had no executive but only advisory powers on the matter, though no doubt their expert opinion carried great weight. But generally speaking they, and especially the chief pontiff, supervised the sacrificial law (*ius divinum*), including the act of "taking" (*capere*) a new flamen Dialis or a vestal virgin. They kept records, the fragments of which (*commentarii pontificum*) are a valuable source for the study of Roman religion. They also kept and published brief accounts of the events of each year, *annales*.

Nothing prevented a pontiff from being also a secular magistrate; Rome had priests, but no priestly class or caste, and secular magistrates regularly had certain sacrificial functions, whether they were pontiffs or not. The only priest absolutely debarred from magistracies was the *rex sacrorum*.

Pontifex is one of the styles by which the pope (*q.v.*) is designated.

See G. Wissowa, *Religion und Kultus der Römer*, vol. ii, pp. 501 ff. (1912); G. Rohde, *Die Kultusregeln der römischen Pontifices* (1936). (H. J. R.)

PONTIFICAL, a book used in some Roman rite ceremonies of the Catholic Church in which one of the participants is a bishop (Lat. *pontifex*). The Latin and proper name is *Pontificale romanum*. It has three main sections: part one deals with the episcopal administration of sacraments and blessings to persons—for example, the conferring of holy orders; part two deals with the blessing of things—for example, the ceremony of consecrating a church edifice; part three has a variety of ceremonies. The prayers of this work were once contained in sacramentaries, and its rubrical directions were in the *ordines*, neither of which species of liturgical book is in use today. (See SACRAMENTARY; ORDINES ROMANI.)

In the middle of the 10th century St. Alban's monastery at Mainz put out a forerunner of the modern *Pontificale romanum* that was widely circulated. About 1292 Guillaume Durand, canonist and bishop, edited a book of episcopal ceremonies with roughly the same order of parts that the *Pontificale romanum* has: rites for the sanctification of persons, rites for the sanctification of objects, and various ceremonies. Durand's work enjoyed some papal approval. The first printed edition was commissioned by Pope Innocent VIII and appeared in 1485. A new edition of this in 1511 was entitled *Pontificale*, and a further edition, edited by Alberto Castellani in 1520, was the basis of Clement VIII's *Pontificale romanum*, the first so called, in 1596. Clement gave this work full official ecclesiastical approval (which none of its predecessors enjoyed) and ordered it to be followed by all bishops in the Roman and kindred

rites. By a decree issued on April 16, 1961, the Congregation of Sacred Rites revised the second part of the *Pontificale romanum*, allowing the other two to remain for the time being as they were except for the introduction into them of revised Gregorian melodies.

See Pierre de Puniet, *The Roman Pontifical: a History and Commentary* (1932); Carolus Braga, "In secundam partem Pontificalis romani," *Ephemerides Liturgicae*, vol. lxxvi, pp. 201-283 (1962). (E.A. A. W.)

PONTINE MARSHES (now known as AGRO PONTINO), an area of about 290 sq.mi. (750 sq.km.) southeast of Rome between the Alban Hills, the Lepini Mountains, and the Tyrrhenian Sea, which was reclaimed by the Italian government before World War II. It is known that two tribes, the Pomptini and the Ufentini, lived in this area in early Roman times, but the region was already marshy and malarial during the later years of the Roman Republic, and the Appian Way traversed it, using the higher, eastern section of the area. The first attempt at reclamation was made in 160 B.C., and subsequently numerous other attempts were made without success. The Pontine Marshes throughout modern history was a region of malaria, inhabited by a handful of shepherds, with small fields on the eastern edge where peasants from towns high on the Lepini Mountains cultivated wheat. Rough pasture and maquis covered most of the area. In 1932-34 the Fascist government launched a spectacular drive to drain the marshes, clear the vegetation, and settle several hundred families. Towns were built in what was wilderness: Latina (earlier Littoria) was established in 1932, Sabaudia in 1934, Pontinia (1935), Aprilia (1937), and Pomezia (1939); rural service centres were constructed, and on the eve of World War II the only areas where the original vegetation remained were in the Monte Circeo National Park. Damage done to the farms and to the drainage works during the fighting in 1944 was later repaired. (G. KH.)

PONTOISE, a town of north-central France, *préfecture* of the *département* of Val-d'Oise (created 1964), lies on the right bank of the Oise at its confluence with the Viosne, 32 km. (20 mi.) NW of Paris by road. Pop. (1962) 14,898. The convent of the Cordeliers, restored in the 18th century, forms part of the *hôtel de ville*. The Tavet Museum nearby is a 15th-century building. The tower (1547) of St. Maclou, a 12th-century church (restored in the 15th-16th centuries), dominates the town. The church of Notre Dame (16th century) contains the tomb of St. Gautier, founder of the abbey of St. Martin de Pontoise. There are remains of the 13th-century Cistercian Abbey of Maubuisson on the left bank of the Oise. A fair is held every Martinmas (Nov. 11). Pontoise is on the Paris-Dieppe railway and is an important market centre.

The town was acquired by Philip I in 1064 and became the capital of the French Vexin. It played a conspicuous part in the wars between the French and the dukes of Normandy and in the Hundred Years' War. The English captured it in 1419 and again in 1437. In 1441 Charles VII took it after a three months' siege. Allied to the Holy League, Pontoise was taken by Henry III and the king of Navarre in 1589. The parliament of Paris met there several times: in 1652 (when it offered a refuge to Louis XIV and Cardinal Mazarin) and in 1720 and 1753. Pontoise passed to the prince of Conti in 1749. It was occupied by the Germans in 1870-71 and was damaged in World War II. (J. M. HA.)

PONTOPPIDAN, HENRIK (1857-1943), Danish writer whose novels and short stories present an unusually comprehensive picture of his country and his epoch, was born at Fredericia on July 24, 1857. His father was a clergyman, and it was partly in revolt against his environment that he began to study engineering in Copenhagen in 1873. In 1879 he broke off his studies and became for several years a teacher. His first collection of stories, *Stakkede Vinger*, was published in 1881, and thereafter he supported himself by writing, until 1900 partly as a journalist with various Copenhagen papers. In 1917 he shared the Nobel prize for literature with Karl Gjellerup. He died at Ordrup on Aug. 21, 1943.

Pontoppidan's output, mainly of novels and short stories, stretches over half a century and covers most aspects of Danish life and the social, political and religious problems of the period.

As a poet he belonged to the naturalist school, though he showed a characteristically critical independence and an agile, dialectic, ironic mind. An individualist and an apostle of the cult of personality, he yet had strong ties with his nation and his compatriots, for whom he had great affection although he criticized them severely.

His first books were mainly descriptions of country-town life, *Landsbybilleder* (1883), *Fra Hytterne* (1887) and *Skyer* (1890) are all characterized by social indignation though also by ironic appreciation of the complacency and passivity of country people. The trilogy *Det forjaettede Land* (1891-95; Eng. trans., *Emanuel*, 1904), *Children of the Soil*, 1892, and *The Promised Land*, 1896) describes the religious controversies in country districts. The chief character is a pastor from Copenhagen, a dreamer who tries, unsuccessfully, to gain the confidence of the peasants. In the 1890s Pontoppidan wrote a number of short novels on psychological, aesthetic and moral problems (e.g., *Nattevagt*, 1894; *Den gamle Adam*, 1895; and *Højsang*, 1896). These were followed by a major work, the novel *Lykke-Per* (1898-1904), in which the chief character bears some resemblance to Pontoppidan himself. He is a clergyman's son who rebels against the puritanical atmosphere of his home and seeks his fortune in the capital as an engineer. But his religious background inhibits him and he loses interest in success and wealth, separates from his Jewish fiancée (who with her strength of will and pride probably represents Pontoppidan's ideal) and after an unsuccessful marriage ends his life in complete loneliness. The book's theme is the power of environment, and national tendencies toward daydreaming and fear of reality are condemned.

Deeper problems are touched on in the shorter novels *Borgmester Hoeck og Hustru* (1905) and *Den kongelige Gaest* (1908), after which follows a third great novel, *De Dødes Rige* (1912-16). This covers the first decade of the 20th century and shows dissatisfaction with political developments after the liberal victory of 1901, and anxiety for the future. It sounds a warning against the barrenness of the new era. Anxiety for the country's destiny also lies behind the bitter novel *Mands Himmerig* (1927), which describes neutral Denmark during World War I and attacks care-free materialism. The cold, aloof, epic style which Pontoppidan had developed during his career is also a feature of his last important work, the four volumes of memoirs which he published between 1933 and 1940 and which appeared in a collected and abridged version entitled *Undervejs til mig selv* (1943).

PONTORMO, JACOPO DA (JACOPO CARRUCCI) (1494-1557), Italian painter, one of the creators of Florentine Mannerism, was born at Pontormo, near Empoli, on May 24, 1494, the son of Bartolommeo Carrucci, a painter. According to Vasari he was apprenticed to Leonardo da Vinci and afterward to Albertinelli and Piero di Cosimo. At the age of 18 he entered the workshop of Andrea del Sarto, and it is this influence that is most apparent in his early works. In 1518 he completed the altarpiece (still in the church of S. Michele Visdomini, Florence); its agitated—almost neurotic—emotionalism marks a departure from the balance and tranquillity of the High Renaissance and makes it one of the first Mannerist pictures. His painting of "Joseph in Egypt" (c. 1515; National Gallery, London), one of a series for Pier Francesco Borgherini, suggests that the revolutionary new style appeared at an even earlier date.

Pontormo was primarily a religious painter, but he painted a number of sensitive portraits and in 1521 was employed by the Medici family to decorate their villa at Poggio a Caiano with mythological subjects. In the Passion cycle (1522-25) for the Certosa near Florence (now in poor condition) he borrows ideas from Dürer, whose engravings and woodcuts were circulating in Italy. His mature style is best exemplified in the "Deposition" painted soon after this for Sta. Felicità, Florence.

Pontormo became more and more of a recluse in later life. A diary survives from 1554-57, but the important frescoes in S.

Lorenzo on which he worked during the last decade of his life are now known only from drawings; in these the influence of Michelangelo is apparent. Numerous drawings survive and paintings are to be found in various galleries in Europe and America, as well as in Florence. Pontormo was buried in Florence on Jan. 2, 1557.

BIBLIOGRAPHY.—F. M. Clapp, *Jacopo Carucci da Pontormo* (1916); E. Bertl Toesca, *Il Pontormo* (1943); Florence, Palazzo Strozzi, *Mostra del Pontormo* (1956).

PONTRESINA, a village in the upper Engadine, canton of Graubünden, Switz., 6 km. (3½ mi.) E of St. Moritz by rail. Pop. (1960) 1,067, mostly Romansh-speaking. Situated at about 6,000 ft. (1,800 m.) above sea level at the junction of the Bernina and Roseg valleys, it is an important winter and summer resort. It is the starting point of the spectacular Bernina railway into Italy. The tourist trade is the town's chief industry. Settled by Celts and Ligurians in the 5th century B.C., the area was invaded in the first century A.D. by Saracens from southern Spain.

(Ot. A. L.)

PONTUS, in ancient geography, a district in northeastern Asia Minor, bordering on the Black Sea (Greek *Pontos*). At first it was reckoned as part of Cappadocia; then, in order to differentiate it from inland Cappadocia, it was described as Pontic (i.e., "maritime") Cappadocia; the name Pontus was a later simplification.

Several mountain chains run through the region in lines from east to west, roughly parallel to the Black Sea coast, divided from one another by the valleys of rivers. The more important rivers are the Halys (modern Kizil Irmak), the Lycus (Kelkit), and the Iris (Yesil Irmak). The fertile ground lies chiefly along the latter two. The higher ground was in ancient times well wooded and contained at certain places rich mineral deposits. Along the coast Greek colonies were established from Miletus at Sinope (Sinop) and Amisus (Samsun) in the 7th century B.C.; subsequently Cotyora (Ordu), Cerasus (Giresun), and Trapezus (Trabzon) were colonized from Sinope. The major centres of native settlement were near the great temples: that of Ma at Comana; that of Men Pharnaku at Cabira; and that of Anaitis at Zela. It was not until the time of the Roman occupation in the late 1st century B.C. that true cities developed in the interior of Pontus.

It may be supposed that the same kind of feudal society as existed in Cappadocia prevailed also in Pontus. The population was very mixed. Apart from the native Cappadocian people and the Iranian settlers who came to the country after the Persian conquest, there were several tribes of separate races occupying various districts. Of the latter the Chalybes, in tradition the first workers of iron (Greek *chalybs*), the Tibareni, the Mossynoeci, and the Macrones are mentioned in the ancient accounts.

The emergence of the region as a political unit of international importance dates from the end of the 4th century B.C. when a Persian nobleman or dynast Mithradates (q.v.) founded there a small kingdom. The capital of the dynasty was at first at Amasia (Amasya) on the Iris, where the rock-cut tombs of four of the kings have been recognized; later the capital became Sinope after that city had been annexed to the kingdom (183). The kings gradually built up the strength of their country, while obtaining from other states the recognition that they had become members of the Hellenistic concert of powers. Many Greeks were employed at the court and in the army, and, like many oriental rulers of the age, the Pontic kings fostered at least a superficial Hellenism throughout their dominions.

In the early 2nd century B.C. an aggressive policy was followed by the king Pharnaces I; Sinope, Cerasus, and Cotyora were annexed by him. But it was not until the accession of the eighth king Mithradates VI Eupator (see MITHRADATES) that the great expansion of the Pontic kingdom began. During his long reign (c. 115–63 B.C.) the kingdom reached its zenith. But his disastrous wars with Rome brought about the loss of most of the kingdom, only the overseas province of the Crimea and its adjoining districts being left to him at the end. Under Pompey's settlement (63–62 B.C.) the western part of the kingdom was attached to Bithynia to form the province of Bithynia and Pontus; and the eastern part was assigned to the Galatians. After 40 B.C. the Pontic kingdom was revived in the eastern districts, but only as a Roman protector-

ate; it was finally reannexed in A.D. 64–65, and was thereafter known as Pontus Polemoniacus (after its former kings Polemo I and II).

See D. Magie, *Roman Rule in Asia Minor*, 2 vol., especially ch. 8 (1950). (R. H. St.)

PONTYPOOL, an urban district in Monmouthshire (q.v.), England, situated approximately in the centre of the county, about 10 mi. (16 km.) N of Newport by road. Pop. (1961) 39,930. It lies in the valley of the Lwyd, a tributary of the Usk River. This north-south valley, colloquially known as the Eastern Valley, divides the mountainous industrial area of the west from the low agricultural country in the east of the county. Pontypool owes its industrial development to its position on the eastern edge of the South Wales coalfield. The first ironworks were erected in 1577 by Edmond Brode, a partner of Richard Hanbury whose name figures so largely in local history. Pontypool was the pioneer in sheet rolling and tin plating and it became famous for wire, cast-iron gates, etc. Specially lacquered decorated ironware was known in the 18th century as Pontypool Japan. The old forges have given place to modern works producing special steel products, glass, and rubber. There are also toy factories and a large nylon plant.

(H. Ck.)

PONTYPRIDD, an urban district of Glamorgan, Wales, is situated on the Taff at its junction with the Rhondda, and on the Glamorgan Canal, 12 mi. (19 km.) NW of Cardiff by road. Pop. (1961) 35,494. It received its name from the remarkable single-span stone bridge over the Taff, erected by William Edwards in 1750. The town has a biweekly street and covered market. On the opposite bank of the Taff is the suburb of Ynysangharad with its fine public park. After the opening of the Taff Vale Railway in 1840, Pontypridd became the railway junction for the Merthyr, Aberdare, and Rhondda valleys. Mainly industrial in character, its manufactures include steel, electrical equipment, chains, and cables, besides its traditional coal-mining industry. An effective balance between the last named and lighter industries was achieved with the establishment in 1937 of the Treforest Industrial Estate (160 ac. [65 ha.]), 2 mi. (3 km.) from the town.

PONY EXPRESS, the name applied in U.S. history to a system for providing fast mail service between St. Joseph, Mo., and Sacramento, Calif., from April 1860 to October 1861. The pony express was established by the freighting and stagecoach firm of Russell, Majors, and Waddell. Expert riders chosen from boys and small men rode fleet horses in relays. They carried half-ounce letters bearing a \$5 pony express stamp and a 10-cent U.S. stamp. A specially designed square of leather, called a *mochila*, was thrown over the saddle, with a hole for the saddle horn and a slit for the cante. The letters were carried in four sole-leather boxes attached to the corners of the *mochila*. The goal of ten-day service between St. Joseph and Sacramento was sometimes achieved.

The route at the outset covered 1,838 mi. and included 157 stations from 7 to 20 mi. apart. "Home stations" were located at intervals of 75 to 100 mi. Each rider changed horses from six to eight times on his scheduled ride from one home station to another. After a rest period he carried the mail in the other direction.

The route followed in general the Oregon-California Trail and passed through Ft. Kearney, Julesburg, Ft. Laramie, South Pass, Ft. Bridger, Salt Lake City, and Carson City. Indians burned stations, killed employees, and otherwise disrupted service in the summer of 1860 during the Paiute War.

Among the best-known pony express riders were William ("Buf-falo Bill") Cody and "Pony Bob" Haslam. Joseph A. Slade was a hard-driving division superintendent. Russell, Majors, and Waddell had introduced the pony express in the hope of winning a mail contract that would save their tottering transportation empire from bankruptcy. In this they failed. Sensational though it was, the pony express was a financial failure when completion of the transcontinental telegraph line in October 1861 ended all need for it.

See Raymond W. and Mary L. Settle, *Saddles and Spurs* (1955); Arthur Chapman, *The Pony Express* (1932). (T. A. Ln.)

PONZA (ancient *PONTIA*), the name of a small group of islands

off the west coast of central Italy about 65 km. (40 mi.) SW of Gaeta. The islands, lying between Rome and Naples, include Ponza (the largest), Palmarola, and Zannone in a western cluster and Ventotene and Santo Stefano in an eastern group. Their total area is 10.9 sq.km. (4.2 sq.mi.); their population (1964 est.) 5,732. Regular steamer services connect Ponza with Naples and, during the summer, with Anzio and Formia. The highest point on the island of Ponza is Monte della Guardia (283 m.; 928 ft.). Kaolin and bentonite are mined on the islands; and they have lately become popular as summer resorts. The island of Ventotene has a prison; under the Fascist regime Ponza was used as a place of banishment for political prisoners. (G. K.H.)

POOL: see BILLIARDS.

POOLE, WILLIAM FREDERICK (1821–1894), U.S. bibliographer, was a pioneer in U.S. periodical indexing and library administration. He was born in Salem, Mass., Dec. 24, 1821. As a student at Yale he became librarian of a literary society; his *An Alphabetical Index to Subjects Treated in the Reviews and Other Periodicals, to Which No Indexes Have Been Published* (1848) appeared a year before his graduation. A second edition of what became *Poole's Index to Periodical Literature* (1887–1908) appeared in 1853. Poole was an assistant in the library of the Boston Athenaeum in 1851; was librarian of the Boston Mercantile Library Association (1852–56); of the Boston Athenaeum (1856–69); served two years as a library consultant; was librarian at the Cincinnati Public Library, which he organized (1871–73); of the Chicago Public Library (1874–87), building it to the largest circulation in the U.S.; and organized the reference library of the Newberry Library, Chicago, where he remained until his death, March 1, 1894, in Evanston, Ill. History was his avocation and he published widely, especially in the *North American Review*.

POOLE, a municipal and parliamentary borough, a county of a town, a port, and seaside resort in Dorset, Eng., 24 mi. (39 km.) E of Dorchester and 5 mi. (8 km.) W of Bournemouth by road. Pop. (1961) 92,111. The name alludes to the remarkable situation of the old town on a peninsula between the almost landlocked Holes Bay and the tidal waterway (7 mi. by 4½ mi. [11 km. by 7 km.]) to the north of Purbeck known as Poole Harbour. A chain ferry operates between South Haven and Sandbanks at the entrance to the harbour, and a lifting bridge to Hamworthy crosses the entry to Holes Bay. On the east, Poole includes Parkstone and Branksome and extends to Bournemouth. It is a great yachting centre and its good sands have gained it popularity as a holiday resort. The southeast coast is formed by chalk cliffs scored by several of the chines characteristic of those parts. Largest of the islands in Poole Harbour is Brownsea (a bird sanctuary, given to the National Trust in 1962) where in 1907 was held the experimental camp from which sprang the Boy Scout movement. There is an old-established pottery, and other industries include boatbuilding, chemicals, agricultural implements, and engineering. Coal, timber, oil, and general merchandise are imported; exports include clay and tar.

Poole, not mentioned until after the Domesday survey, was granted its charter in 1248. It is uncertain when the burgesses obtained their town at the fee-farm rent of £8 13s. 4d. mentioned in 1312. In 1372 they obtained assize of bread and ale and right to hold courts of the lord of the manor. Elizabeth I made it a separate county in 1569.

POONA (PUNE), a city, district, and division of Maharashtra, India. The city, headquarters of the district and division, lies at the confluence of the Mutha and Mula rivers, 1,850 ft. (564 m.) above sea level and 119 mi. (192 km.) SE of Bombay on the Central Railway. Pop. (1961) 597,562, excluding cantonment. It has a temperate and pleasant climate, and is known as the "Queen of the Deccan" because of its historical associations, its picturesque surroundings, and its importance as a cultural, educational, and political centre. It was the centre of the Mahratta (Maratha) Empire for more than 100 years and the monsoon capital of the Bombay presidency under British rule. The old government house at Ganeshkhind is now the home of Poona University (founded 1948). It has 14 central departments and a large number of constituent and affiliated colleges, including those of arts and science,

medicine, commerce, agriculture, law, and engineering.

Several departments of the Maharashtra government have headquarters at Poona, which is also the headquarters of the southern command of the Indian Army and of the Poona subarea. The Indian National Defence Academy is at Khadakvasla, 10 mi. (16 km.) from the city. The College of Military Engineering and the Armed Forces Medical College are also in Poona. The Indian naval and mechanical training establishment, the I.N.S. "Shivaji," with its engineering college, is at Lonavla, 40 mi. (64 km.) NW of Poona. Other institutions are the Institute of Armament Studies and the Artificial Limb Centre, the only one of its kind in India. Poona is supplied with water from the Khadakvasla dam and electricity comes from the Tata group of hydroelectric works in the hills nearby.

The city has a municipal corporation consisting of 65 corporators who annually elect their mayor. A civilian officer of the Maharashtra government functions as the chief executive officer of the corporation and is known as the municipal commissioner. The cantonments of Poona (pop. [1961] 65,838) and Kirkee or Khadki (58,496) adjoin the city area.

In the city of Poona itself and in the adjoining cantonments are a number of places of historical association: e.g., the remains of the famous Shaniwarwada Palace of the peshwas and the Aga Khan's palace where M. K. Gandhi was held in custody in 1942. To the southwest of the city is Parvati Hill, so named after the temple of Durga, or Parvati, on its summit. Public gardens include the Bund Gardens, laid out beside the stone bund (dam) on the Mula River, the Empress, and the botanical gardens. There are a number of museums and churches, a synagogue, and several hospitals. Poona has a cotton mill, a paper mill, and a few metal and engineering factories. The National Chemical Laboratory and the meteorological department observatory are also at Poona. Kirkee contains a large ammunition factory, and there is a penicillin factory at Pimpri, a few miles away. Poona is an important rail and road junction.

POONA DISTRICT has an area of 6,033 sq.mi. (15,625 sq.km.). pop. (1961) 2,466,880. Toward the west the country is undulating and numerous spurs from the Western Ghats enter the district; to the east it opens out into plains. The region is liable to drought. The two most important irrigation works are the Mutha Canal with which the Poona waterworks are connected, and the Nira Canal. The main crops are jowar and paddy. Jaggery is produced in great quantities from sugarcane, and there are several sugar factories. The district is traversed by the Central Railway and also by the Southern Railway, which runs southward from Poona city to Miraj and Belgaum.

The district contains a number of historical places which include the Shivneri Fort, the birthplace of Sivaji (q.v.), and the well-known Karli (q.v.) caves.

POONA DIVISION comprises the districts of Poona, Ahmednagar, Satara, Sangli, Kolhapur, and Sholapur. Area 28,909 sq.mi. (74,874 sq.km.). Pop. (1961) 10,360,282. (D. G. K.)

POOR CLARES, the Second Order of St. Francis, an order of contemplative nuns founded in 1212 by St. Clare (Clara) of Assisi.

See FRANCISCANS: *Second Order*; CLARE, SAINT.

POOR LAW. A series of enactments culminating in the English Poor Law of 1601 provided for minimal relief for the destitute through a poor rate levied on all householders, thus for the first time establishing secular and legal obligations to aid the unfortunate, in addition to the previously recognized moral and religious duties to give alms for the poor. Though the causes of this development were many, they were all basically connected with the breakdown of the medieval economy and social structure of western Europe, which both destroyed the traditional framework of charity and produced new types of poverty.

For the origins of charitable institutions, the early influences of Buddhism, Islam, Judaism, and Christianity and the development and decline of medieval philanthropic institutions see PHILANTHROPY. For the development of modern programs to aid those in need see CHILD WELFARE; SOCIAL SECURITY; SOCIAL SERVICE; SOCIAL WELFARE.

ENGLAND AND WALES

In medieval England poverty had been largely due to an underdeveloped economy in which famine and pestilence were recurring phenomena. By the beginning of the 16th century this kind of destitution was giving place to the "dearth in the midst of plenty" which so perplexed contemporaries. Enclosure for pasture was blamed for unemployment, depopulation, and vagrancy. The rising price level, resulting from a complex combination of the influx of treasure from the New World and the disastrous monetary debasements of Henry VIII and Edward VI, was popularly attributed to the mania for sheep farming. The breakdown of the medieval rural economy, deplorable as it seemed to contemporaries, must not be exaggerated; the areas affected by enclosure for sheep were very limited. It was the expansion of the woolen industry, with its close dependence on foreign markets, which was often responsible for this kind of unemployment. The cycle of boom and slump had come to add a new element of instability to the economic life of England. Of less importance in the creation of Tudor poverty is that cause which loomed so large in early accounts of the origin of the poor law, the dissolution of the monasteries. By 1536 many of these were too embarrassed financially to do more than relieve the local beggars their presence attracted. The legend that hordes of monks and nuns were turned adrift to beg their bread has not been substantiated by later research.

This new type of poverty was not confined to England; it was appearing in all the more economically advanced countries of western Europe. It is customary to attribute the pattern of early Tudor legislation to the influence of Juan Luis Vives' *De subventionem pauperum sive de humanis necessitatibus*, published in 1526. This formed the basis of the experiment of dealing with poverty by municipal action undertaken at Ypres in 1525, an account of which appeared in an English translation in 1535. But foreign influences may have been overestimated; similar causes were everywhere likely to suggest similar remedies. That the crown evinced any interest in the destitute was attributable to politics, not compassion. Vagrants spread disaffection and might provide the raw material for a rebel army. The early efforts of the government, therefore, were directed to stamping out vagrancy. The relief of poverty was left, with some general directives, to local authorities. The first statute dealing specifically with poor relief was that of 1531, which merely empowered justices to license aged and impotent persons to beg within their own neighbourhood. The interlocking problems of destitution, unemployment, and vagrancy seem to have been under discussion in 1535, as in that year draft proposals outlined revolutionary suggestions for dealing with them, including the employment of the able poor on public works and the setting up of both central and local administrative machinery. The statute of 1536, as finally passed, was less drastic and concentrated largely on the organization of voluntary funds for the relief of those unable to work. Despite its lack of administrative machinery, it, like the previous draft, illustrates the new approach to the problem and for this reason is often regarded as the first English poor law. In line with continental opinion it prohibited begging and indiscriminate charity, and attempted to classify the poor into the aged and impotent needing relief, and poor children who should be apprenticed. In practice, lacking administrative machinery, it could be put into effect only where the municipal authorities had the organization to finance and implement its provisions. London, Norwich, and York were among those towns confronted with turning theory into fact.

London took the lead. A serious attempt to deal with the City's poor soon showed that funds provided by voluntary contributions were insufficient, and in 1547 the corporation decided to impose a compulsory poor rate. A new administrative device of the greatest importance was thus introduced, and there was a decisive break with the medieval conception of charity as a religious duty. Other expedients of a modern character followed rapidly. By 1553 a comprehensive scheme for the treatment of the poor was in existence. They were now classified as the poor by impotency, the poor by casualty, and the thriftless poor, and appropriate institutional treatment was to be provided, as far as resources would allow, for each group. Similar programs were initiated by other

cities, particularly those whose connection with the fluctuating fortunes of the woolen industry increased the instability of employment. By the end of the 1570s many of them had evolved workable schemes based on classification, some measure of institutional treatment and compulsory rates.

Before 1572 the state provided little legislation to underpin this system and it looked as if the relief of poverty would become the responsibility of the towns rather than of the nation. Indeed a characteristic feature of the English poor law is the way in which national legislation followed, rather than initiated, local experiment. This, until the adoption of the civil parish as the unit of poor law administration, was dictated by the fact that the central authority had no effective machinery through which to administer statute law locally. It was only in the sphere of providing funds, therefore, that a few fumbling advances were made by the acts of 1551-52 and 1563. Not until 1572 was a straightforward, compulsory rate imposed on a national scale. By then it was clear that the state would have to take a more active part in enforcing on local authorities some responsibility for destitution. The same act also ordered the compilation of a comprehensive register of persons needing relief and instructed justices in rural areas and mayors in towns to appoint collectors and overseers. It also, like the earlier draft of 1535, recognized the fact that not all the unemployed were work-shy; local authorities were now encouraged to use funds left over from the relief of the aged, sick, and infant poor to set the able-bodied pauper "on work" (i.e., provide work for the able-bodied). In 1576 this permission was transformed into compulsion. All local authorities were to provide funds for the purchase of raw materials for this purpose.

The "Old Poor Law" (1601).—The codification of 1597-98, reenacted in 1601 with minor changes and finally made permanent in 1623, completed the first stage of the poor law (sometimes known as the Elizabethan poor law or the "old poor law" in contradistinction to the "new poor law" set up after 1834). The parish, the smallest unit of local government, was finally and decisively acknowledged as the normal unit of administration. This was entrusted to overseers, appointed annually by the local justices and forced to serve under penalty of a fine, who, together with the churchwardens, were to assess and levy a poor rate on all householders which, when ratified by the justices, was compulsory. With these funds the aged were to be relieved and provided, if necessary, with cottages on the waste, or common, poor children were to be apprenticed, and the able poor set "on work." This codification was at once a synopsis of previous urban experience and a break with urban experiments, since the parish, a smaller but ubiquitous unit, was now the basis of the national system. Though later the parish was to prove too small, it is difficult to see what else could have been done. Experience had shown that poor relief confined to the towns put too heavy a burden on them and distributed rather than relieved destitution.

The subsequent period, from 1597 to 1644, is of fundamental importance in the history of the poor laws; in these years the privy council succeeded in building up an administrative hierarchy to make the earlier acts effective. It is easy for the modern citizen to forget how great was the gap between enactment and enforcement in Tudor England and to assign to early acts a practical importance which they could not possess. After 1597 the exertion of pressure on the justices and the sending of directives became more frequent. Sometimes these took the form of general orders, such as those sent to all high sheriffs and courts of quarter sessions in 1598 to explain the new legislation; sometimes they were concerned with particular problems and were sent to individual authorities. Until 1622 this kind of pressure was irregular, being called into being in response to a sudden crisis, either local or national. The failure of the harvests in 1621 and 1622 and in 1629-31 apparently converted an occasional expedient into a regular routine. Since 1597 the privy council had had experience in dealing with the regulation of grain supplies under scarcity conditions and in 1631 it applied this experience to its system of supervision of the local poor law authorities. The system was both practical and detailed. The justices of each county were to divide themselves into groups, so many being responsible for each subdivision, or hundred

(*q.v.*). They were to hold monthly meetings with the churchwardens and overseers of the parishes within their respective hundreds, to punish neglect by these officers of their statutory duty, and to report what had been done every three months to the high sheriff. These reports were sent to the justices of assize and finally submitted to the privy council. In this way it was possible, at least in theory, for the central government to get a picture of the way in which the local authorities were carrying out their tasks.

The general impression is one of real but geographically patchy success. Where the pressure of work was not great, or where local charity and endowments were adequate, or the parish remote and difficult to supervise, the poor, if assisted at all, were helped without much reference to the letter of the law. For example, the parish of Sawston in Cambridgeshire levied no regular poor rates until 1658. In contrast, where towns and cities had long been grappling with the problem, or in those rural areas where the justices were accessible to pressure, parishes seem to have been relieving the aged and sick, apprenticing their children and even complying with the obligation to have a "town stock" of raw materials with which to set the poor "on work."

With the outbreak of civil war and the determined attack of the Long Parliament on the coercive power of the privy council, the situation altered. Authorities were once again left to their own devices. The statutory obligations remained but the encouragement and supervision disappeared, not to return until the creation of the poor law commissioners in 1834. Nevertheless, the pressure of the previous 40 years was not without results. The habit of appointing overseers, levying rates, relieving the poor, had become something of a social tradition. It might not be well done, and the difficult task of organizing employment was often dropped, but the laws, far from falling into abeyance, were gradually extended into parishes and areas where earlier they had been little observed.

Parish Organization of Poor Relief, 1662-1795.—The next milestone in the history of the English poor law came with the restoration of the monarchy. There was no attempt to revive the control of any central authority, but in 1662 the responsibility of each parish was defined by an act usually known as the Law of Settlement and Removal. Its preamble contained the statement that "by reason of some defect in the law, poor people are not restrained from going from one parish to another, and do therefore endeavour to settle themselves in those parishes where there is the best stock, the largest commons or wastes to build cottages and the most woods for them to burn and destroy." To remedy this defect the act provided that any person coming into a parish who neither rented a house of the annual value of £10 (which was a rental completely outside the economic resources of the craftsman or labourer) nor was able to give security against becoming a burden on the rates at any future time, could be moved back to his or her place of settlement within 40 days on application made by the overseers to two local justices for a warrant of removal. There was nothing very new in this act except in the precise definition of the occasion and method of removal. The piecemeal legislation of the Tudors, before the final codification of 1601, contained assumptions that the right to relief was a local one, that parishes were entitled to some defense against an influx of strangers and need not relieve, might indeed even remove, "aged, lame or impotent persons" of less than three years' residence. Sixteenth-century municipal authorities had been zealous in removing persons likely to become chargeable. The act of 1662 thus gave national force to existing local custom.

The legal basis for the custom however had never been clearly defined, though most communities seem to have felt that people had a right to relief only where they lived and were known. Charity both began and ended at home. Even so, why the task of definition should have been undertaken just when it was has been something of a puzzle to historians. The general upheaval and unsettlement of the years after the Civil War and interregnum is usually adduced as the most likely cause. The growth of population may well have been an additional reason.

However it may be, the act of 1662 with its subsequent amendments was thenceforth the hub around which the administration of the poor law revolved. In 1685 it was amended so that the

40 days' residence necessary to gain a settlement only began from "the time of his or her Delivery of a Notice in Writing of the house of his or her Abode, and the Number of his or her Family, if he or she have any, to one of the Churchwardens or Overseers of the said Parish." In 1693 the regulations were further tightened by the stipulation that the notice in writing had to be read in the parish church at the time of divine service. After this there was little chance of a stranger's gaining a settlement without the consent of the general body of the ratepayers. In an attempt to make the act work in a reasonable way, the same statute also defined other methods of gaining a settlement. These were by serving an apprenticeship within the parish, by being hired as a servant for a year, by executing some parochial office for the same period, or by paying parochial rates. In addition, women gained a settlement on marriage, and legitimate children took that of their father until they reached the age of seven, when they could acquire one of their own. Illegitimate children were settled where they were born.

Effects of Settlement Laws.—Between 1662 and 1795, after which date no person could be removed until he was actually chargeable, the attempts of parish officers to take advantage of the settlement laws distorted almost every aspect of the poor laws except the granting of relief to those aged and sick paupers who were, beyond all doubt, the settled poor of the parish. Despite the condemnation of Adam Smith, the purely economic effect of this legislation appears to have been slighter than might have been expected. Some elasticity was given by an act of 1697, which gave legal sanction to the existing practice by which parishes gave testimonials to parishioners seeking work elsewhere: these were, in effect, promises to take them back should they ever become chargeable. Moreover it was clearly impossible to remove every newcomer, particularly where there was a demand for labour. In practice, able-bodied men, so long as they took no steps to obtain a settlement by presenting a notice in writing, rarely seem to have been removed unless they were actually chargeable. Rural parishes appear to have concentrated on removing married couples, particularly those "overburdened with children." Single women, women with children, and orphans were equally unpopular. In industrial areas where young and old could be employed, the family unit was less economically vulnerable. Here women, particularly those with children, were the main victims. In any case the changing distribution of the growing population of the 18th century makes it clear that mobility could not have been unduly restricted.

If the economic consequences of the Law of Settlement were not notably harmful, the social consequences can be more justifiably condemned. Apprenticeship, originally intended to give a child a start in life, was now often used to change its settlement. Children could be compulsorily bound out in their own parishes or, with funds provided from the poor rate, elsewhere. In this case no one questioned the suitability of the master or the trade selected, or the treatment the child received. In this matter the urban parishes appear to have been the chief offenders. The result was many runaway apprentices and much misery. Another unfortunate result was the restriction on the building of new cottages on the commons, which led to overcrowding and the retarding of marriage. Unmarried mothers were treated with great harshness. An act of 1576 had made it an offense to beget an illegitimate child which was likely to become chargeable, and the father, if known, could be forced to give security "to save the parish harmless." Little proof beyond the woman's oath was required, and many men, guilty or innocent, found refuge in flight. In such cases the overseers, faced with the responsibility for the child, forced or bribed the woman to take to the roads. Yet whether this widespread distortion of the poor laws really saved parish funds may be doubted. Removals were expensive and often contested at quarter sessions; sometimes they were taken on appeal to higher courts. Moreover, though each parish struggled to save itself expense, it was in turn the victim of similar practices by other parishes.

The best-administered part of the poor law appears to have been the relief of those aged and sick persons who were unquestionably settled inhabitants. Indeed, care had to be taken to keep this kind of relief within bounds. After 1693 none was to be given

except in case of emergency, without the authority of a justice, the names of such persons to be entered in a book and reviewed annually. Paupers whose claims were allowed received small monthly pensions, though by the act of 1697 they were ordered to wear a large red or blue P on their outer garment. Often their rent was paid and they got occasional gifts of fuel and clothes. Sick paupers were looked after, medical attention that ranged from the services of a bonesetter to those of the local doctor was provided, and, if death followed, the parish paid funeral expenses.

The Workhouse.—The obligation to set the poor "on work" was the most difficult of all the burdens placed on the parish by the act of 1601. To manage a parish stock at a profit was well-nigh impossible. Municipal experiments on the lines of the London Bridewell tended to peter out, while the houses of correction, which an act of 1607 ordered to be set up in every county, were increasingly regarded as penal establishments for the idle rather than as places of employment. Once the supervision of the privy council disappeared, the first phase of the attempts to employ the poor came to an end in 1644. After the Restoration the increasing interest taken in political economy refocused attention on this failure to employ the poor. Emphasis was now placed on the loss to the national income sustained through the waste of labour, and many pamphleteers, among whom were John Bellars, Richard Haines, and Thomas Firman, outlined schemes for the organization of corporations to employ the poor on a commercial basis. For this purpose stock was to be subscribed and workhouses erected. Most schemes were quite impracticable, but John Cary started a new chapter in poor law history when he persuaded the Bristol parishes to apply for a local act to set up a "Corporation of the Poor" in 1696. This was to be responsible for the poor of the entire city and provide employment for them in a well-run workhouse. At first the experiment appeared successful, and Bristol's example was followed by other towns. These early hopes were not maintained, but workhouses became established institutions largely for their deterrent value. In 1723, indeed, a permissive general act allowed parishes to build and manage workhouses and to refuse relief to those who would not enter them. Though useful in keeping down the poor rate, such workhouses made no effective contribution to setting the poor on profitable work. During the 18th century they rapidly degenerated into mixed receptacles of misery where every class of pauper, vicious or unfortunate, young or old, sick, well, or lunatic, was dumped. Sometimes they were managed by parochial officials, often they were let out to contractors, either for a lump sum or on a capitation basis. Many parishes fluctuated from one method to the other but neither led to any satisfactory employment of the poor.

Humanitarians were increasingly troubled by the abuses of the general mixed workhouse, while there were increasing complaints about the inadequacy of the parish as a unit for poor law administration on the grounds that it was too small (particularly in the towns) for effective action, and that its unpaid, annually appointed, untrained officers were either lazy or corrupt. Indeed, some parishes, though without legal sanction, were already employing a salaried overseer. An act of 1782 permitted parishes to unite for the purpose of building institutions to house all classes of the destitute, except the able-bodied. For the able-bodied the overseers, in vague terms, were directed to provide relief or work outside the house. This meant a complete reversal of earlier policy in a revulsion from its failure.

Speenhamland System (1795).—Between 1782 and 1793 economic depression, poor harvests, and frictional unemployment caused by agricultural developments and the early stages of industrialization combined to make life difficult for the labouring poor. Wages often were traditional and bore little relation to changing conditions. Yet, to men steeped in mercantilist thought, it appeared plain folly to raise wages to meet what, to contemporaries, must have seemed a temporary crisis. It had long been the practice to help poor men "overburdened with children" by making them some allowance from the parish. In the same way temporarily soaring prices, caused by a failure of the harvest, were commonly met by *ad hoc* emergency relief measures rather than by raising wages. In line with this tradition the justices of

Berkshire, meeting at Speen in the district of Speenhamland in 1795, decided that wages below what they considered an absolute minimum should be supplemented by the parish in accordance with the price of bread and the number of dependents a man had. Their example was widely followed and the practice received parliamentary confirmation in 1796. Yet another phase of English poor law history, the so-called Speenhamland system, had begun.

(D. M.L.)

The word "system" is misleading, for the Speenhamland decision was a makeshift, grounded in existing social theory and practice, rather than a deliberate proposal for a general poor law policy. Even in Berkshire itself, the decision did not result in any substantial changes in local administration. Parishes continued to maintain their own workhouses, to give or to withhold casual relief, to distribute cheap food, and to fix bread prices. During the Napoleonic Wars, however, there was a great extension of the allowance system, or various types of allowance systems, in the southern counties of England, and contemporaries found it convenient to describe this as part of one general process. Most historians have agreed with contemporary critics that the spread of the allowance system was "momentous" and "disastrous."

The "system" had three possible abuses. First, it might lead to the subsidization of wages out of the poor rate. In *The State of the Poor* (1797), Sir F. M. Eden claimed that the larger farmers were able to take advantage of the magistrates' benevolence by forcing the smaller ratepayers, who were not themselves employers of labour, to augment wages. The charge may have been exaggerated, for some tenant farmers were able to pass on the increase in poor rates to their landlords, but such a transfer was not general and did not prevent the poor rate from becoming a redistributive tax. Second, it might entail the general pauperization of large numbers of employed workers on the land. It was argued that the system made the poor careless and indifferent, checked their incentive to save, encouraged improvident marriages, and engendered a large increase in population which, according to Malthusian theory, would inevitably create a new mass of poverty. Some opponents even went so far as to argue that all poor laws should be abolished; as Thomas Chalmers put it, "no evil genius could have designed a system of greater malignity for the corruption of the race." Third, it sharpened the contrast between industrial north and agrarian south and perpetuated the division of the labour market into two sectors, the one depending upon a contractual wages system, the other depending upon status and protection. Controversy centred on these points not only during the Napoleonic Wars but also after 1815, when agrarian discontent was accompanied by industrial expansion.

Between 1815 and 1830 contemporaries were mainly concerned, however, with the burden of poor law expenditure, particularly in the area south of the Wash-Severn line. In 1785 the total cost of poor law administration was a little less than £2,000,000; by 1803 it had increased to a little more than £4,000,000; and by 1817 it had reached the total of almost £8,000,000. This final figure represented a cost of about 13s. 3d. per head of the population or about one-sixth of total public expenditure. Although the total fell a little in the subsequent 15 years, it did not fall as much as the price level, and in 1832 it stood at about £7,000,000, or 10 s. per head of the population. Some parishes were particularly affected by the burden. One Buckinghamshire village, for instance, reported in 1832 that its expenditure on poor relief was eight times what it had been in 1795 and more than the rental of the whole parish had been in that year. In face of statistics of this kind, the Whig government decided to intervene, and in the year of reform, 1832, a royal commission was appointed to inquire into the whole "system." Its recommendations served as the basis of the reforms embodied in the Poor Law Amendment Act, 1834.

New Poor Law (1834).—The new act was not merely a return to severity after a period of benevolence; it was inspired by new principles and set up new administrative machinery. The case for abolition of the poor laws was not accepted, but on Benthamite lines it was laid down that poor relief should be granted to able-bodied poor and their dependents only in well-regulated workhouses under conditions inferior to those of the humblest labourers out-

side. As the commissioners had argued, "every penny bestowed that tends to render the condition of the pauper more eligible than that of the independent labourer is a bounty on indolence and vice." The machinery also was Benthamite. The hitherto independent parishes were grouped into unions, each under an elected board of guardians, with a strong central authority—the Poor Law Commission—to enforce a uniform policy.

On paper, the act of 1834 introduced order into the poor law system; in the words of Nassau Senior, one of its chief architects, it was "a measure of social policy." Poverty was considered a crime, which merited a stigma, and the poor were poor not because Providence had ordained them to be so but as a result of their own failings. Such a harsh philosophy, which was sharply criticized by traditionalists and helped to rouse the Chartist movement, was nonetheless better suited to the mood of an industrial age than Speenhamland. One of the purposes of the act was to stimulate free trade in labour by driving workers onto the labour market. The abolition of outdoor relief was intended to provide an incentive to workers to seek regular employment. Unfortunately, however, when the poor law commissioners attempted to apply the act in the north of England in 1837, there was much genuine industrial unemployment.

Less Eligibility.—The inadequacies of the act were demonstrated very clearly during the subsequent 30 years. The first and most dramatic crisis in its administration came in 1847 at Andover. The workhouse there was so efficient in applying the principle of less eligibility (*i.e.*, that the condition of the poor should be made "less eligible" than that of the labourer) that labourers were willing to accept as little as 5s. or 6s. a week rather than enter the workhouse, for work conditions imposed on inmates were intolerably cruel. A committee set up to investigate conditions at Andover condemned its internal administration and led to the setting up of a new Poor Law Board (1847), directly responsible to Parliament, in place of the Poor Law Commission. The president of the board was now eligible to sit in Parliament. Some improvement in workhouse conditions followed the Andover scandal, but in 1852 an experienced lawyer, Robert Pashley, maintained that "the workhouse as now organized is a reproach and disgrace peculiar to England: nothing corresponding to it is to be found throughout the whole Continent of Europe."

There was an inevitable reaction in the middle of the century against the excessive harshness of poor law administration. The attempt to treat as one group all children, women, and men in need of assistance was bound to create social as well as administrative difficulties. To place under the same stringent discipline the young, the sick, the aged, and the able-bodied proved as much of a strain to the administrators as it was a grievance to the poor themselves. The new poor law, in consequence, became almost as subject to local variation as the old poor law of the 17th and 18th centuries. In many parts of the country it proved impossible totally to abolish outdoor relief; in other parts, separate poor law institutions were created for the young and the sick; and in some districts, boards of guardians continued to pay small weekly doles to old men and women incapacitated from work. Such signs of "sentimentalism" were bitterly attacked by the faithful supporters of the principles of 1834. The development of democracy, however, associated as it was with the growth of humanitarian feeling, and, after 1880, the development of more scientific methods of dealing with destitution, helped to mitigate the harshness of poor law administration.

Extension of the Franchise.—The extension of the franchise in 1884 (which extended the household and lodger franchise to the counties, nearly tripling the county electorate; see PARLIAMENT: *The Franchise*) was an important turning point in the approach to the poor. From that date onward a move away from the principles of 1834 can clearly be traced. In 1891 supplies of toys and books for workhouses were permitted; in 1892 tobacco and snuff could be provided; in 1893 visiting committees of ladies were allowed to inspect the workhouses; in 1894 guardians were given the right to distribute dry tea, milk, and sugar for women to make their own afternoon tea; in 1897 trained nurses could be employed for the care of the sick poor; and in 1900 a government circular recom-

mended the grant of outdoor relief for the aged of good character.

In addition to these deviations from the principle of less eligibility, changes were made in the fiscal and administrative machinery for supervising the poor laws. In 1871 the Poor Law Board was abolished and central authority passed directly to the Local Government Board. The new body was as much concerned as the old one had been with fiscal surgery as well as social policy, and throughout its existence it emphasized the most important social bulwark of 1834, the assertion that poverty deserved a stigma. Men and women in receipt of relief under the poor law were not only subject to a special discipline and compelled to wear pauper uniforms as a symbol of their inferiority; they were robbed of their civil and political rights, including the right to vote. The poor law treated the claims of the poor not as an integral part of the rights of the citizen, but as an alternative to them—as claims which could be met by society only if the claimant ceased to be a full citizen of the community. It was not until 1918 that the pauper disability of disfranchisement was removed, and even after that signs of the stigma still remained.

Criticism and Reform.—The changed approach both to poverty and to the poor law began with a new inquiry into the facts of destitution in the last 20 years of the 19th century. Charles Booth's *Life and Labour of the People in London*, the first volume of which was published in 1889, was the first great landmark. It was followed by other important books, such as Seebohm Rowntree's *Poverty: A Study of Town Life* (1901), which gave a new precision to the concept of poverty. Further evidence collected by official committees, particularly the Royal Commission on the Aged Poor, which reported in 1895, helped to direct attention both to existing practices and to basic presuppositions about the poor. The way was prepared for setting up the Royal Commission on the Poor Laws in 1905.

Unlike the commission of 1832, that set up in 1905 was not the outcome of any sustained agitation, nor did its members start with any common theory to apply to the contemporary situation. "There is no one directing purpose shaping the enquiry to a predetermined end," wrote Beatrice Webb, one of the members, in the middle of the deliberations, "which of the many conflicting or diverging purposes will prevail remains to be seen." But the commission included many experts in dealing with the poor. Some like Sir Charles Loch, had experience with both poor law and voluntary charity; some, like Charles Booth, Helen Bosanquet, and Beatrice Webb herself, had been leaders in social study and research; others, like George Lansbury and Francis Chandler, were representatives of the new labour upsurge as well as experienced guardians; and finally there was Octavia Hill, who had done more than any other woman for the welfare of the London poor. If these distinguished members of the commission had been unanimous, they would, said Canon S. A. Barnett, have been invincible.

In fact no single purpose prevailed and two reports were produced by the commissioners. The majority (16) recommended that the boards of guardians should be replaced by statutory committees of the county and county borough councils, that the new committees should be called "public assistance authorities" with a number of subordinate public assistance committees working under them in subareas, and that general workhouses should be abolished and different classes of the destitute should be relieved in specialized institutions. The able-bodied poor should, as far as possible be found work, but outdoor relief could be provided after strict inquiry, under supervision, and on a uniform basis.

The minority (four) were not content with this retreat from the principles of 1834. They argued that the poor law system was fundamentally bad. It was the business of the community to try to prevent destitution and not merely to palliate it when it occurred. In consequence, the poor law should be broken up, and in its place the state and the local authorities should provide specialized social services to deal with separate categories of poor people. Already administrators had been compelled to note the existence of the sick, the feeble-minded, the aged, and pauper children as well as the able-bodied. Now the able-bodied should be placed in charge of a national unemployment authority and the other categories should be transferred to the local authorities.

Both majority and minority expressed themselves strongly against the views of the surviving supporters of 1834, particularly J. S. Davy, the principal officer of the poor law division of the Local Government Board. There was a remarkable measure of agreement in the condemnation of the past and the assessment of the present. There were two distinct views of the future, however, each of which was to prove influential. The minority report, drafted with skill and driven by passion, advocated optimum social services maintained by specialists, the boundaries of whose activities would be set by the boundaries of perfection in their own expert techniques. In the middle of the picture would be a registrar of public assistance for each local authority, coordinating the various schemes. The majority report, building on the social situation as it existed in 1905, was more concerned with minimum social security than with the optimum, and more conscious of the continued role of voluntary action, maintained by an army of trained general or family caseworkers. If the minority report seemed to point more clearly toward the welfare state, it was opposed to the insurance principle on which the welfare state was to be constructed.

Breakup of the Poor Law.—No action was taken in 1909 to implement the proposals of either the majority or the minority reports, although Beatrice Webb set up the National Committee for the Promotion of the Break-up of the Poor Law, and Lord George Hamilton created an alternative National Poor Law Reform Association.

The government did not respond to the arguments of this agitation, and within the poor law structure itself undertook merely a mild so-called revolution by administration. It did, however, herald a genuine revolution in welfare policy, and by introducing such measures as old age pensions without "the stigma of pauperism" and national insurance it placed the poor laws in a new legislative and administrative context.

It was not until 1929, however, after a period of prolonged enquiry and economic and political disturbance during the 1920s, that the Local Government Act implemented the main recommendation of both the 1909 reports by replacing the boards of guardians by local authorities. The Poor Law Act, 1930, consolidated previous legislation. The minister of health was charged with the central direction and control of all matters relating to the administration of poor relief; in the localities, most authorities appointed separate public assistance committees, consisting of elected members of the council plus (optionally) a number, not exceeding one-third of the total, of persons co-opted from outside the council. In addition there were subordinate guardians' committees for appropriate workhouse areas in the counties, although they had no power to appoint or dismiss officers without the approval of the public assistance committees. The chief local administrator of the poor law was the public assistance officer, who sometimes was also the clerk of the council. He was assisted by the district relieving officer, the direct descendant of the Elizabethan parish officer.

The passing of the new legislation coincided with an alarming increase in the number of unemployed and the darkest period of industrial distress in the whole of English history. The break up of existing social policy in the 1930s was the prelude to reforms introduced during and after World War II, which marked a radically new approach to social welfare (*q.v.*). (A. Brl.)

UNITED STATES

Public provision for the care of persons in economic need in the United States is as much a part of North America's English heritage as the right of trial by jury. Before the first year at Plymouth ended, it was necessary for members of the colony to call upon their experience in the homeland to assure food, shelter, and clothing to the least fortunate members of the colony. The Elizabethan Poor Law of 1601 was a codification of many various acts and decrees dating back to the 14th century, and the colonists drew upon this experience to deal with their own community problems.

Classification of the Needy.—As in England, two principal classes of needy persons were recognized: (1) the able-bodied, and

(2) children plus the permanently incapacitated. Able-bodied adults were to be put to work, and children were to be trained for self-support through apprenticeship. The lame, the sick, and the aged were given what in that age was regarded as humane care. In New England each town was responsible for its own poor. The classical poor law formula was less commonly used in the South, partly because of indenture, slavery, and the plantation system.

Local Administration.—The Elizabethan Poor Law was an act of the national government, but it was administered by the local authorities. The American adaptation was at first simply a derivative from the English law, but eventually it became part of the colonial codes and still later part of the statutes of the several states. Hence, the problem of the "settlement" of the needy arose. Where did he live and, therefore, who was responsible for him and his family? From the earliest colonial days a needy person had to apply for assistance in the local governmental unit in which he had settlement. The ancestor of poor law settlement was the medieval doctrine that every man had a master and was bound by rights and obligations to some feudal domain. The growth of population disturbed the validity of this assumption. The rise of the doctrine of a free labour market in the 18th century, supplemented by the population theory of Thomas R. Malthus, dealt settlement doctrine a staggering, though not fatal, blow.

Criterion of Need.—During the 19th century in the United States as in Great Britain, to be eligible for assistance the recipient had to have less income than he could earn at the lowest-paid job in the community, and the rule was that he should not be given as much as he could earn at such a job if one were available. This was the doctrine of "less eligibility."

During the period since 1930 a new phrase has been used to indicate the amount of assistance to be given, namely, that necessary to maintain "health and decency." For one thing this took account of all members of the family in terms of what was required for physical health and respectable appearance. The operational definition of "health and decency" is made by the local assistance agency. The tendency has been to remove fixed maximum amounts of money to be paid to needy persons. Some agencies are generous, but others are restrictive and still make grants within the tradition of less eligibility.

Multiplication of Categories of Assistance.—Instead of the two categories in the old poor law, needy persons since 1900 have been classified into several administrative categories: mothers and dependent children, the aged, the blind, the permanently disabled, and then the residue. Illinois adopted the first Mother's Aid Law in 1911, and Montana set up a special old age pension scheme in 1923. Both of these categories derive from the "unemployable" category of the old poor law. Under the Federal Social Security Act a national system is administered through the states but usually still by town or county agencies. The "health and decency" criterion is more or less in use.

A new system of categories came into existence with the first social insurance laws in Germany in the 1880s, later in Great Britain, and still later in the United States. Benefit under social insurance is payable, not because somebody is necessarily in economic need, but because an "insurance event" has occurred. Money is paid according to a scale from funds accumulated for the purpose. Social insurance for the unemployed, the aged, survivors, the disabled, the blind, and the sick provides a substitute for earned income to prevent or reduce need for public assistance.

General assistance is nearer to the old poor law than are the categories. Only economic need must be shown to establish eligibility, and it is determined on the basis of all members of the household.

The Poor Law Transformed.—The poor law in purpose and to a considerable extent in method has been transformed into social service and social welfare (*qq.v.*). Hence, it may be said "that the primary objective of public welfare services is to develop, restore, or maintain working capacity, to promote socio-psychological adjustment, to provide humane care of the incapacitated, and to establish facilities for the attainment of these ends, and in so doing to maintain a morale and a sense of security which are necessary to an orderly government." (R. Clyde White, *Ad-*

ministration of Public Welfare, p. 7, American Book Company, 1950.)

POORWILL, the name (from its cry) of a North American bird (*Phalaenoptilus nuttallii*) of the nightjar family (Caprimulgidae). It is about eight inches long; the primaries are rusty gray, barred with black. It breeds in arid country west of the Mississippi north to British Columbia and south to southern California.

Poorwills are cited as classic examples of hibernation among birds; they cling to the walls of rock crevices and remain in a torpid state during the unfavourable winter months. See also BIRD: *Natural History and Habits: Resting, Sleeping, and Hibernating*.

POPAYÁN, a city in southwestern Colombia, capital of the department of Cauca, is located on a tributary of the Cauca River. The city lies on a deep deposit of volcanic debris from adjacent Puracé Volcano (16,306 ft. [4,970 m.]) and from other nearby volcanoes, such as Sotará (14,550 ft. [4,435 m.]) and Pan de Azúcar (15,321 ft. [4,670 m.]). Founded in 1537 by Sebastián de Belalcázar, the city has always been a seat of government of secondary rank. During colonial times many great landowners and entrepreneurs in placer mining resided there, and Popayán became a major cultural and religious centre. It is still important for its educational institutions. The changing pattern of economic activity in Colombia since independence has reduced Popayán's significance, although the city has contributed major political, religious, and literary figures to the nation. Its population (58,500 in 1964) has fallen far behind that of such cities as Cali and Pasto which were once subordinate to it. Situated off the main lines of modern commercial traffic, Popayán is now a minor industrial and transportation centre. Its industrial activity is largely focused on food and beverage preparation, clothing, and building materials. Coffee and sugar are produced in the surrounding area. Popayán is on both the Pacific Railway and the Simón Bolívar Highway, a part of the Pan-American Highway connecting the Cauca Valley with Ecuador. The city lies at the centre of an extensive departmental road network. (R. L. GE.)

POPE (Latin PAPA, from Greek PAPPAS, "father"), an ecclesiastical title expressing affectionate respect, formerly given, especially from the 3rd to the 5th century, to any bishop and sometimes to simple priests, still used in the East for the Orthodox patriarch of Alexandria and for Orthodox priests, but since the 9th century reserved in the West exclusively for the bishop of Rome, in his capacity as sovereign pontiff or head of the Roman Catholic Church (as distinct from his lesser offices and dignities: patriarch of the Western Church, primate of Italy, archbishop and metropolitan of

the Roman province, local bishop of the diocese of Rome, sovereign of the Vatican City-State). Even in the case of the sovereign pontiff the word pope or *papa* (abbreviated PP.) is officially used only as a less solemn style: though the ordinary signature and heading of briefs, encyclicals, and other lesser documents is, e.g., "Paulus PP. VI," the signature of solemn documents such as bulls is *Paulus episcopus ecclesiae catholicae*, and the heading, *Paulus episcopus, servus servorum Dei*, this latter formula going back to the time of Pope St. Gregory the Great (d. 604). Other styles met with in official documents are *Pontifex*, *Summus pontifex*, *Romanus pontifex*, *Sanctissimus*, *Sanctissimus pater*, *Sanctissimus dominus noster*, *Sanctitas sua*, *Beatissimus pater*, *Beatitudo sua*; while the pope is addressed in speaking as "Sanctitas vestra," or "Beatissime pater."

According to Roman Catholic doctrine, whoever succeeds St. Peter in the see of Rome holds, by the plan of Christ himself, Peter's primacy—the full and supreme power of ruling and teaching the entire church (hence not a primacy merely of honour or inspection or direction). The bishop of Rome is therefore, like Peter, Christ's vicar, the visible head of the church on earth, while Christ remains its invisible and one chief head. In virtue of his primacy, the Roman pontiff has full and supreme jurisdiction over the whole church in all matters pertaining to faith, morals, church government, and discipline. This papal jurisdiction exceeds the power not only of any individual bishop but also of all the bishops taken collectively (without the pope). It can be exercised in dioceses outside Rome at any time, and not only through the bishops of those dioceses but also directly upon the individual flocks and individual members of those flocks. Because of this direct pastoral authority over the entire church the pope is sometimes called "the bishop of the Catholic Church." Included in his primacy is the supreme power of teaching the whole church in matters pertaining to faith and morals. This power is employed above all (though not only) when the pope speaks *ex cathedra*, in which case he is infallible, that is, cannot make a mistake and teach error (see INFALLIBILITY). These primatial powers of ruling and of teaching, even infallibly, having been claimed and exercised by the popes in the course of centuries, were solemnly defined at the first Vatican Council (July 18, 1870), which reiterated, clarified, and amplified earlier conciliar pronouncements.

For the history of the papacy and associated questions, see PAPACY; CONCLAVE; CARDINAL; VATICAN; and biographies of the different popes. See also references under "Pope" in the Index.

POPE, ALEXANDER (1688–1744), the most distinguished of the classical poets of the Augustan age and the most accomplished verse satirist in English. He was born in Lombard Street, London, on May 21, 1688. His father, a wholesale linen merchant, retired from business in the year of his son's birth, and in 1700 went to live at Binfield in Windsor Forest. The Popes were Roman Catholics, and at Binfield they came to know several neighbouring Catholic families who were to play an important part in the poet's life. Pope's religion procured him some lifelong friends, notably the wealthy squire John Caryll (who persuaded him to write *The Rape of the Lock*, on an incident involving Caryll's relatives) and Martha Blount, to whom Pope addressed some of the most memorable of his poems—the second *Moral Essay*, *To Mrs. M. B.* on

THE BETTMANN ARCHIVE
ALEXANDER POPE, ENGRAVING BY J. PESSLEWHITE FROM A PORTRAIT BY THOMAS HUDSON

Her Birthday, and *An Epistle to Miss Blount with the Works of Voiture*—and to whom he bequeathed most of his property. But his religion also precluded him from a formal course of education; he was trained at home by Catholic priests for a short time and attended Catholic schools at Twyford, near Winchester, and at Hyde Park Corner, London; but he was mainly self-educated. He was a precocious boy, eagerly reading Latin, Greek, French, and Italian, which he managed to teach himself, and an incessant scribbler, turning out verse upon verse in imitation of the poets he read. The best of these early writings are the "Ode on Solitude" and a paraphrase of St. Thomas à Kempis, both of which he claimed to have written at the age of 12. But perhaps in later life he believed himself to have been more precocious than he was.

Early Works.—Windsor Forest was near enough to London to permit Pope's frequent visits there. He early grew acquainted with former members of Dryden's circle, notably William Wycherley, William Walsh, and Henry Cromwell, the recipients of his earliest surviving letters, which are devoted to a somewhat mannered discussion of the art of poetry. By 1705 his "Pastorals" were in draft and were circulating amongst the best literary judges of the day. In 1706 Jacob Tonson, the leading publisher of poetry, had solicited their publication, and they took the place of honour in his *Poetical Miscellanies* in 1709.

This early emergence of the man of letters may have been assisted by Pope's poor physique. As the result of too much study, so he thought, he acquired a curvature of the spine and some tubercular infection which limited his growth, and seriously impaired his health. His full-grown height was four feet six inches; but the grace of his profile and fullness of his eye attracted numerous painters (such as Sir Godfrey Kneller and Charles Jervas) and sculptors (such as John Michael Rysbrack and Louis François Roubillac), who have transmitted his likeness in such variety as to make his iconography more extensive than that of any other English writer before Dr. Johnson. He was a lifelong sufferer from headaches and his deformity made him abnormally sensitive to physical and mental pain; but though he was able to ride a horse and delighted in travel, he was inevitably precluded from much normal physical activity, and his energetic, fastidious mind was largely directed to reading and writing.

When the "Pastorals" were published Pope was already at work on a poem in an equally well-established tradition, on the art of writing. This was *An Essay on Criticism*, published in 1711. Its brilliantly polished epigrams (e.g., "A little learning is a dangerous thing," "To err is human, to forgive divine," and "For fools rush in where angels fear to tread"), which have become part of the proverbial heritage of the language, are readily traced to their sources in Horace, Quintilian, Boileau, and other critics, ancient and modern, in verse and prose; but the charge of plagiarism, so often made in the past, obscures Pope's success in harmonizing a century of conflict in critical thinking and in showing how Nature may best be mirrored in Art.

Following the well-deserved success of the *Essay on Criticism* came a wider circle of friends, notably Richard Steele and Joseph Addison, who were then collaborating in *The Spectator*. To this journal Pope contributed the most original of his pastorals, *Messiah* (1712), and perhaps other papers in prose. He was clearly influenced by its policy of correcting public morals by witty admonishment, and in this vein wrote the first version of his mock-epic, *The Rape of the Lock* (two cantos, 1712; five cantos, 1714), to reconcile two Catholic families. A young man in one family had stolen a lock of hair from a young lady in the other. Pope treated the dispute that followed as though it were comparable with the mighty quarrel between Greeks and Trojans which had been Homer's theme. Telling the story with all the pomp and circumstance of epic made not only the participants in the quarrel but also the society in which they lived seem ridiculous. But though it was a society where

. . . Stain her honour, or her new brocade,
Forget her pray'rs, or miss a masquerade;

Pope managed also to suggest what genuine attractions existed amidst the foppery and glitter. He acknowledged how false the sense of values was that paid so much attention to external appearance; but ridicule and rebuke slide imperceptibly into admiration and tender affection as the heroine Belinda is conveyed along the Thames to Hampton Court, the scene of the "rape":

But now secure the painted vessel glides
The sunbeams trembling on the floating tides,
While melting music steals upon the sky,
And soften'd sounds along the waters die.
Smooth flow the waves, the zephyrs gently play,
Belinda smil'd, and all the world was gay.

A comparable blend of seemingly incompatible responses—love and hate, bawdiness and decorum, admiration and ridicule—is to be found in all Pope's later satires.

Pope had also been at work for several years on *Windsor Forest*. In this poem, completed and published in 1713, he proceeded, as Virgil had done, from pastorals to georgics, and celebrated the rule of Queen Anne as the Latin poet had celebrated the rule of Augustus. By choosing for its background a region so rich in historical associations, he was enabled to prophesy the greater glories of regenerate and peaceful society.

In yet another of these early poems, *Eloisa to Abelard*, Pope borrowed the form of Ovid's "heroic epistle" (in which an abandoned lady addresses her famous lover) and showed remarkable imaginative skill in conveying the struggle between sexual passion and dedication to a life of celibacy.

Translation of Homer.—These poems, with *Verses to the Memory of an Unfortunate Lady* (modeled on the elegies of Ovid and Tibullus), some translations from the classics, and a few shorter pieces, were collected in the first volume of Pope's *Works* in 1717. This is a volume of experiments in various poetical kinds; it might almost be called a volume of juvenilia. When it was published, he was already far advanced with the greatest labour of his life, his verse translation of Homer. He had announced his intentions in October 1713, and had published the first volume, containing *Iliad*, Books I–IV, in 1715. The *Iliad* was completed in six volumes in 1720. The work of translating the *Odyssey* (vol. i–iii, 1725; vol. iv and v, 1726) he shared with William Broome, who had contributed notes to the *Iliad*, and Elijah Fenton (qq.v.). The labour had been great, but so were the rewards. By the two translations he cleared about £10,000 and was able to claim that, thanks to Homer, he could ". . . live and thrive/Indebted to no Prince or Peer alive."

The merits of Pope's *Homer* lie not in the accuracy of translation nor in representation of the spirit of the original, but in the achievement of a heroic poem as his contemporaries understood it, a poem Virgilian in its dignity, moral purpose, and pictorial splendour, yet one which consistently kept Homer in view and alluded to him throughout. Pope offered his readers the *Iliad* and the *Odyssey* as he felt sure Homer would have written them had he lived in early 18th-century England.

Political considerations had affected the success of the translation. As a Roman Catholic his affiliations were Tory rather than Whig, and though he retained the friendship of such Whigs as William Congreve, Nicholas Rowe, and Charles Jervas the painter, his ties with Steele and Addison grew looser owing to the political animosity at the end of Queen Anne's reign, and he found new and lasting friends in Tory circles, Swift, John Gay, John Arbuthnot, Thomas Parnell, the earl of Oxford, and Viscount Bolingbroke (qq.v.). With the first five he was associated (1713–14) in the Scriblerus Club (see LITERATURE, SOCIETIES OF) to write joint satires on pedantry, later to mature as *Peri Bathous*; or the *Art of Sinking in Poetry* (1728) and the *Memoirs of Martinus Scriblerus* (1741); and these were the men who encouraged his translation of Homer. The Whigs, who associated with Addison at Button's Coffee-House, put up a rival translator in Thomas Tickell, who published his version of *Iliad*, Book I, two days after Pope's. Addison preferred Tickell's manifestly inferior version; his praise

. . . Britain's statesmen oft the fall foredoom
Of foreign tyrants, and of nymphs at home;

as if one occupation concerned them as much as the other; and though in such a society a young lady might do equally ill to

increased the resentment he had already given Pope by a series of slights and misunderstandings; and when Pope heard gossip of further malice on Addison's part, he sent him a satirical view of his character published later as the character of Atticus, the insincere arbiter of literary taste in the *Epistle to Dr. Arbuthnot* (1735), but with the most topical couplet omitted:

Who when two wits on rival themes contest,
Approves them both, but likes the worst the best.

The stages in this famous quarrel and the partial reconciliation that followed remain obstinately obscure; but Pope's subsequent praise of Addison in the verse epistle first published in Addison's works and in the *Epistle to Augustus* is generous and genuine.

"**The Dunciad.**"—Even before the Homer quarrel, Pope had found that the life of a wit was a perpetual warfare. There were few years between 1711 and 1718 when either his poems or his person were not objects of attacks from the critic John Dennis, the notorious bookseller Edmund Curll (*q.v.*), the historian John Oldmixon, and other writers of lesser fame. The climax was reached over his edition of Shakespeare. He had emended the plays, in the spirit of a literary editor, to accord with contemporary taste (1725); but his practice was exposed by the scholar Lewis Theobald (*q.v.*) in *Shakespeare Restored* (1726). Though Pope had ignored some of these attacks, he had replied to others with squibs in prose and verse. But he now attempted to make an end of it, and defended his standards, which he aligned with the standards of civilized society, in the mock-epic, *The Dunciad* (1728). Theobald was represented in it as the Goddess of Dullness' favourite son, a suitable hero for those leaden times; and others who had given offense were preserved like flies in amber. Even if the individuals can no longer be recognized, what they stand for can usually be appreciated. Thus to conclude the "heroic" games in Book II, the Goddess prescribes a gentler exercise to discover

... What author's heaviness prevails,
Which most conduce to soothe the soul in slumbers,
My Henley's periods, or my Blackmore's numbers?
Attend the trial we propose to make:
If there be man who o'er such works can wake.

Three Cambridge undergraduates are summoned to read from these prescribed authors, and so soporific is the effect that even the most clamorously persistent scribblers amongst the audience are forced into silence:

As what a Dutchman plumps into the lakes,
One circle first, and then a second makes,
What Dullness dropt among her sons imprint
Like motion, from one circle to the rest;
So from the midmost the nutation spreads
Round, and more round, o'er all the sea of heads.
At last Centlivre felt her voice to fail,
Old James himself unfinish'd left his tale,
Boyer the state, and Law the stage gave o'er,
Nor Motteux talk'd, nor Naso whisper'd more;
Norton, from Daniel and Ostrea sprung,
Blest with his father's front, and mother's tongue,
Hung silent down his never-blushing head;
And all was hush'd, as Folly's self lay dead.

In this and several other passages Pope dispatches his victims with such sensuousness of verse and imagery that the reader is forced to admit that if there is petulance here, as has often been claimed, it is, to parody Wordsworth, petulance recollected in tranquillity. Pope reissued the poem in 1729 with an elaborate mock-commentary of prefaces, notes, appendices, indexes, and errata; this burlesque of pedantry whimsically suggested that *The Dunciad* had fallen a victim to the spirit of the times and been edited by a dunce.

His Life at Twickenham.—Pope and his parents had moved from Binfield to Chiswick in 1716. There his father died (1717), and in 1718 he and his mother rented a villa on the Thames at Twickenham, at that time a small country town where several Londoners had retired to live in rustic seclusion. This was to be Pope's home for the remainder of his life. There he entertained with studied modesty such friends as Swift (who returned from

Ireland in 1726, and stayed with Pope while seeing to the publication of *Gulliver's Travels*), Bolingbroke, Oxford, and Jonathan Richardson, the painter, regaling them on gudgeons and flounders from the Thames at his door and on figs and walnuts from the little garden which he took such pains to design and cultivate. The famous grotto, which provided a tunnel under the main highway and formed a study, ornamented by Pope with rare minerals, is all that survives. He kept his own boatman to row him downstream on his frequent visits to London, and his own coach to take him on his customary round of summer visits to country houses, the duke of Argyll's at Adderbury, Lord Bathurst's at Cirencester, Lord Cobham's at Stowe, Ralph Allen's at Prior Park, Bath, and Lord Peterborough's at Southampton. These friends were all enthusiastic gardeners, and it was Pope's pleasure to advise and superintend the laying out of their grounds on the best romantic principles, formulated in his verse *Epistle to the Earl of Burlington* (1731). This poem, now known as *Moral Essay, Epistle IV*, is one of the most characteristic works of his maturity, a rambling discussion in the manner of Horace on false taste in architecture and design, with some suggestions for the worthier employment of a nobleman's wealth.

"**Essay on Man**" and *Related Poems.*—Pope now began to meditate a new work on the relations of man, nature, and society. This was evidently to be such another grand organization of human experience and intuition as Milton had attempted in the 17th century, and Wordsworth was to attempt in the 19th; but he was destined never to complete it. He told Joseph Spence that the following lines, later incorporated in the *Essay on Man*, would have conveyed its dominant tone and interest:

Laugh where we must, be candid where we can,
But vindicate the ways of God to man.

An Essay on Man (1733–34) was intended as the introductory book discussing the grand design. The poem has often been charged with shallowness and philosophical inconsistency. There is indeed little that is original in the thought, almost all of which can be traced in the work of the great thinkers of western civilization. It is not strictly an argumentative poem so much as a discourse, or extended monologue delivered by the poet to a friendly auditor. As becomes a good conversationalist, he alters his mood from time to time, now grave, now gay, colloquial at one moment, formal at another, now affirmative, now quizzical. He deliberately prefers the middle flight to the sublime; but within that range he uses all the arts of diction and versification, the charm of imagery, and variation of rhythm to effect his persuasion. Subordinate themes were treated in greater detail in *Of the Use of Riches, an Epistle to Allen Lord Bathurst* (1732), *An Epistle to Richard Lord Cobham, Of the Knowledge and Characters of Men* (1733), and *Of the Characters of Women, an Epistle to a Lady* (1735), later rearranged as *Moral Essays*, III, I, and II, respectively. He was deflected from this "system of ethics in the Horatian way" by the renewed need for self-defense. The character of "Timon," an ostentatious nobleman in the *Epistle to Burlington*, was reported to represent the duke of Chandos, who had generously subscribed to Pope's *Homer*. Though the report was malicious, it was plausible enough to rouse Pope's apprehensions. This attack and others of a like nature drove him to consider his position as satirist. He chose to adapt for his own defense the first satire of Horace's second book where the ethics of satire are propounded, and after discussing the question in correspondence with Dr. John Arbuthnot (*q.v.*), he addressed him an *Epistle* in verse (1735), one of the finest of his later poems, in which were incorporated fragments written over several years. His case was the satirist's traditional case, that depravity in public morals had roused him to stigmatize outstanding offenders beyond the reach of the law, concealing the names of some and representing others as types, that he was innocent of personal rancour and habitually forbearing under attack.

"**Imitations of Horace**"—"New Dunciad."—The success of his first *Imitation of Horace* (1733) led to the publication (1733–38) of ten more of these paraphrases of Horatian themes adapted to the contemporary social and political scene. Pope's poems fol-

lowed Horace's satires and epistles sufficiently closely for him to print the Latin on facing pages with the English; but whoever chose to make the comparison would notice a continuous enrichment of the original by parenthetical thrusts and compliments as well as by the freshness of the imagery. Thus Horace declares that he is a peace-loving fellow, "but he who provokes me (better not touch me, I cry) will weep for it and be well-known in song throughout the city"; while Pope, in following him, not only glances at Sir Robert Walpole and his French counterpart, Cardinal Fleury (at that time both anxious for peace), but enlivens the whole passage:

Peace is my dear delight—not Fleury's more;
But touch me, and no Minister so sore,
Whoe'er offends, at some unlucky time
Slides into verses, and hitches in a rhyme,
Sacred to ridicule his whole life long,
And the sad burden of some merry song.

The series was concluded with two dialogues in verse, republished as the *Epilogue to the Satires* (1738), where, as in the *Epistle to Dr. Arbuthnot* (1735), Pope ingeniously combined a defense of his own career and character with a restatement of the satirist's traditional apology. These *Imitations* and dialogues show Pope at his easiest and most genial in manner. In them he directed his attack upon the materialistic standards of the commercially minded Whigs in power and upon the corrupting effect of money, while restating and illustrating the old Horatian standards of serene and temperate living. His anxiety about prevailing standards was shown once more in his last completed work, *The New Dunciad* (1742), reprinted as the fourth book of a revised *Dunciad* (1743), in which Theobald was replaced as hero by Colley Cibber (*q.v.*), the poet laureate and actor-manager, who had not only given more recent cause of offense but seemed a more appropriate representative of the degenerate standards of the age. In *Dunciad*, Book IV, the culture of the city of London was seen to overtake the court and seat of government at Westminster, and the poem ends in a magnificent but baleful prophecy of anarchy. He had begun work on *Brutus*, an epic poem in blank verse, and on a revision of his poems for a new edition, but neither was complete on his death at Twickenham on May 30, 1744.

Personality, Poetic Genius, and Reputation.—In the *Epistle to Dr. Arbuthnot* and the *Imitations of Horace* Pope had presented himself to his readers as he would have them see him. He supplemented this defense of his character by editing a selection of his letters. To publish them himself seemed an offense against modesty; he therefore arranged for copies to be placed in the hands of Curll, a bookseller whose taste for piratical publication ensured that a "surreptitious" edition would be produced. The stratagem succeeded (1735), and enabled Pope to complain that he was injured in his reputation and must bring out a correct and authentic edition (1737). Other stratagems were required to secure the publication of his letters to Swift (1741) without his open connivance. Collation of the printed texts with such manuscripts as have survived shows that Pope published a text not substantially different from that which his correspondents read, though he felt himself free to repair his syntax and to readdress a few letters from correspondents who had kept many to correspondents who had kept none. These and his many other surviving letters reveal him at first as a young man labouring successfully to be a wit in the Restoration manner, but show him later in a more sympathetic light as a dutiful son, a kind and thoughtful friend, a well-bred host, a disinterested critic of society, warm in wishes for his country's good, patient under attack, a man of plain living, high thinking, and unimpeachable integrity. Not every critic of Pope has been able to accept this picture; his friendliest critics could wish that he had been less accustomed to equivocation and devious dealings; but when allowances have been made for this and for the too relentless pursuit of some who had injured him—Lady Mary Wortley Montagu, for example, though why Pope came to hate this famous "blue-stocking" for whom he had once expressed a gallant admiration is still obscure—the picture obtained from the letters is convincing, though somewhat conscious in its pose. The picture is paralleled in the later poems, where Pope frequently describes himself as a model of modest, honourable,

contented living, a survival of old Roman simplicity in an age of degenerate taste.

Pope's favourite, but not invariable metre, was the ten-syllable rhyming ("heroic") couplet. He handled it with increasing skill and adapted it to such varied purposes as the epigrammatic summary of the *Essay on Criticism*, the pathos of *Verses to the Memory of an Unfortunate Lady*, the mock-heroic of *The Rape of the Lock*, the discursive tones of the *Essay on Man*, the rapid narrative of the Homer translation, and the Miltonic sublime of the conclusion of *The Dunciad*. But his greatest triumphs of versification are found in the *Epilogue to the Satires*, where he moves easily from witty, spirited dialogue to noble and elevated declamation, and in the *Epistle to Dr. Arbuthnot*, which opens with a scene of domestic irritation suitably conveyed in broken rhythm:

Shut, shut the door, good John! fatigu'd, I said,
Tie up the knocker, say I'm sick, I'm dead!
The Dog-star rages! nay 'tis past a doubt,
All Bedlam, or Parnassus, is let out:
Fire in each eye, and papers in each hand,
They rave, recite, and madden round the land;

and closes with a deliberately chosen contrast of domestic calm, which the poet may be said to have deserved and won during the course of the poem:

Me, let the tender office long engage
To rock the cradle of reposing age,
With lenient arts extend a mother's breath,
Make languor smile, and smoothe the bed of death,
Explore the thought, explain the asking eye,
And keep a while one parent from the sky.

His command of diction is no less happily adapted to his theme and to the type of poem, and the range of his imagery is remarkably wide. He has been thought defective in imaginative power, but the case cannot be sustained in view of the invention and organizing ability shown notably in *The Rape of the Lock* and *The Dunciad*. His standing as a poet was not only recognized at home. He seems to have been the first English poet to enjoy contemporary fame in France, Italy, and Switzerland, and to see translations of his poems into modern as well as ancient languages. Soon after his death different standards began to prevail; but even when his stock was at its lowest, in the 19th century, he found such champions for his poetry as Byron, Lamb, and Hazlitt, and for his letters as Thackeray; and he has long been restored to the esteem if not to the preeminence he enjoyed in his lifetime.

See also references under "Pope, Alexander" in the Index.

BIBLIOGRAPHY.—*Editions, Correspondence, and Selections:* Pope published the first collected ed. of his poems in 1717, adding a 2nd vol. in 1735. Thereafter not a year passed until his death (1744) without some of his earlier writings being reissued. His literary executor, William Warburton, later bishop of Gloucester, published *The Works*, with Pope's corrections, additions, and improvements, 9 vol. (1751); though it purported to be complete, every subsequent editor has added some piece to the canon. The standard edition of the poems is the Twickenham Edition, general editor, John Butt, 6 vol. (1939–61), to be completed with the translation of Homer in 4 vol. (1966). There is a one-vol. version of the complete text of the first six vol. with selected notes, ed. by John Butt (1963). *The Prose Works of Alexander Pope, 1711–20*, vol. 1, was ed. by Norman Ault (1936). The standard ed. of Pope's *Correspondence* is by George Sherburn, 5 vol. (1956). There are convenient selections of his poetry in Everyman's Library, ed. by Bonamy Dobrée (1956); in the Globe Library, ed. by A. W. Ward (1869); and of his letters, ed. by John Butt (1960), in the "World's Classics Series." See also *Selections from Pope*, ed. by George Sherburn (1929); reissued as *The Best of Pope*, (1931). Still briefer selections are *Pope: Poetry and Prose*, ed. by H. V. D. Dyson (1933); *Poems*, selected by Douglas Grant for the Penguin Poets (1951); *Selected Poetry and Prose*, ed. by W. K. Wimsatt (1951); *Selected Poems and Letters*, ed. by R. P. C. Mutter and M. Kinkead-WEEKES (1961). The translation of Homer is reprinted in the "World's Classics Series," 2 vol. There are separate editions of the *Memoirs of Martinus Scriblerus*, by C. Kerby-Miller (1950) and of *The Art of Sinking in Poetry (Peri Bathous)*, by E. L. Steeves (1952).

An important development has been the production of Pope's poetical manuscripts in facsimile, with transcript and editorial notes. The following had been published by 1964: *Windsor Forest*, ed. by R. M. Schmitz (1952); the *Epistle to Bathurst*, ed. by E. R. Wasserman (1960); *An Essay on Criticism*, ed. by R. M. Schmitz (1962); *An Essay on Man*, ed. by Maynard Mack (1963). See also John Butt, *Pope's Poetical Manuscripts* (1954).

Bibliography: The standard bibliography is R. H. Griffith, *Alexander Pope: a Bibliography*, 2 vol. (1922-27).

Biography: The best of the early biographies was that of Dr. Johnson, in his *Lives of the Poets* (1781); he had access to the most important primary document (apart from Pope's letters), J. Spence's *Anecdotes* of his conversations with Pope and others, which was eventually published, ed. by S. W. Singer (1820); a much fuller edition from the manuscripts, by J. M. Osborn appeared in 1965. New facts were gathered by R. Carruthers in his *Life*, 2 vol. (1853; rev. ed. 1858); by C. W. Dilke, whose papers, mainly on the authenticity of Pope's letters, were published as *The Papers of a Critic*, 2 vol. (1875); and by Norman Ault in *New Light on Pope* (1949). The standard biography so far as it goes (1927) is George Sherburn's *The Early Career of Alexander Pope* (1934). Edith Sitwell, *Alexander Pope* (1930), and Bonamy Dobrée's short *Alexander Pope* (1951) are sympathetic studies, using already known facts.

Criticism: The first substantial study of Pope's poetry was by Joseph Warton in *An Essay on the Writings and Genius of Mr. Pope* (vol. 1, 1756; vol. 2, 1782). The best early critical appreciation is by William Hazlitt, in *Lectures on the English Poets* (1818). Of 20th-century assessments, the most important are G. Tillotson, *On the Poetry of Pope* (1938; rev. ed. 1950), and *Pope and Human Nature* (1958); and R. A. Brower, *Alexander Pope: the Poetry of Allusion* (1959). Of many shorter studies the most rewarding are by George Sherburn, "Pope at Work," in *Essays on the Eighteenth Century Presented to David Nichol Smith* (1945); and by Maynard Mack, "Wit and Poetry and Pope: Some Observations on His Imagery," in *Pope and His Contemporaries: Essays Presented to George Sherburn* (1949) and "The Muse of Satire," *Yale Review*, vol. 41 (1951). On specific poems the following studies are noteworthy: E. N. Hooker, "Pope on Wit: *The Essay on Criticism*," in *The 17th Century: Studies by R. F. Jones and Others* (1951); D. Knight, *Pope and the Heroic Tradition* (1951), on the *Iliad*; Aubrey L. Williams, *Pope's Dunciad* (1955); Robert W. Rogers, *The Major Satires of Alexander Pope* (1955). There is a useful reprint of critical studies entitled *Essential Articles for the Study of Alexander Pope*, ed. by Maynard Mack (1964). (J. E. Br.)

POPE, JOHN (1822-1892), Union general in the American Civil War, was born in Louisville, Ky., March 16, 1822. He graduated from the U.S. Military Academy at West Point, N.Y., in 1842 and served as an engineer until the outbreak of the Mexican War, in which he served with distinction. At the outbreak of the Civil War he was named a brigadier general of volunteers. His success with a small independent command in the campaign to open the Mississippi River in the spring of 1862 led Pres. Abraham Lincoln to call him east to lead the Army of Virginia in the defense of Washington, D.C., and to cooperate in Gen. George B. McClellan's peninsular campaign against Richmond. Partly because of lack of experience and tact, Pope failed to enlist the wholehearted support of his subordinates. McClellan's abandonment of the peninsular campaign enabled Gen. Robert E. Lee to turn his full attention to Pope's army before McClellan could join him and to defeat him disastrously at the second Battle of Bull Run (Aug. 29-30). He was relieved of command and held no important post during the remainder of the war. He served competently until his retirement in 1886, rising to the rank of major general in 1882. He died at Sandusky, O., on Sept. 23, 1892. (C. W. Te.)

POPISSH PLOT: see OATES, TITUS.

POPLAR, the name commonly applied to several species of trees comprising a subgeneric group of the genus *Populus*, belonging to the willow family, the Salicaceae (q.v.). Aspens (q.v.), also members of the genus *Populus*, comprise a second subgeneric group. Several of the poplars are better known in some areas as cottonwoods. This name alludes to their minute, air-borne, hairy-tufted seeds, which are released in profusion, and which in accumulations suggest cotton. Others, with fragrant, balsamic-resinous winter buds, are commonly called balsam poplars. (Buds of aspens are essentially nonresinous.)

Populus comprises a group of about 35 species of rapid-growing but short-lived softwood trees, and a number of natural hybrids. These are widely distributed through the northern hemisphere and range from northern Africa through Eurasia and North America; a few species extend even beyond the Arctic circle.

The leaves of poplars are alternate, deciduous, and are mostly triangular to oval in outline, with finely to coarsely toothed margins and long, cylindrical and tapering, or laterally compressed petioles. The sexes are separate in poplars, with the flowers of both sexes borne in long drooping catkins (aments) in advance of leaf emergence. Flowers on staminate (male) trees consist of 12 to 60

stamens inserted in a cuplike disk subtended by a many-fingered bract (those of the aspens with but 6 to 12 stamens). Flowers from pistillate (female) trees are composed of a single two- to four-cell ovoid to globular ovary surmounted by a large spreading stigma, and are similarly inserted on a disk with bract attached. The fruit, a thick-walled (thin-walled in aspens) two- to four-

JOHN H. GERARD

(LEFT) CATKINS AND (RIGHT) LEAVES AND COTTONY SEED MASSES OF EASTERN COTTONWOOD (*POPULUS DELTOIDES*)

valved capsule, contains many minute seeds clothed in cottony pubescence.

There are about a dozen poplars and cottonwoods, including stable varieties and natural hybrids, indigenous to and widely distributed through North America, exclusive of central and southern Mexico.

The eastern cottonwood (*P. deltoides*), a large tree with coarse, deeply furrowed bark and triangular-shaped leaves, which are about as broad as long, often attains a height of 150 or more feet and a diameter of 48 to 96 in. Ranging from Quebec westward to Montana and south to Florida and Texas, it is not only a pulpwood and timber tree of major importance, but it is also planted in many localities as a street and shade tree. Numerous forms of this poplar are ornamentals in both Europe and America, several of which are hybrids with the European black poplar (*P. nigra*) or one of its varieties. Among these are the Carolina poplar (*P. × canadensis* [hybrid between *P. deltoides* × *P. nigra*]), a vigorous tree with strongly ascending limbs, widely used in parks and streets; and the Eugene poplar (*P. canadensis eugenei* [hybrid between *P. deltoides* × *P. nigra italica*]), a tree of narrow-pyramidal habit that originated in France in 1832. Pistillate trees of the two forms have never been found.

The black cottonwood (*P. trichocarpa*) is the largest of the American poplars, and not infrequently attains a height of more than 200 ft. and a diameter of more than 80 in. It is found along the Pacific slope from southern coastal Alaska to Lower California, and eastward in Canada to Alberta and in the United States to western Montana and Nevada, but is most abundant at low elevations. Reaching its maximum development on deep, moist alluvial or sandy soils, it is often the first tree species to become established on newly formed sand bars and flood plains. While very abundant in some areas, the black cottonwood was unexploited for many years, due in large measure to a preponderance of readily accessible softwood timber of higher quality throughout its range. Since the early 20th century, however, it has been harvested in ever increasing quantities for use in the production of lumber, slack cooperage, excelsior, veneer and paper pulp.

The balsam poplar or the tacamahac (*P. balsamifera* [*tacamahoca*]), the "liard" of the early Canadian voyageurs, is a large tree of transcontinental distribution, with a pyramidal crown and shal-

low root system. Essentially a Canadian tree, it occurs along the northern border of the United States from New England westward through the lake states and northern Rocky mountains to Oregon and Washington. Northward it ranges from Labrador westward across nearly all of Canada to beyond the Arctic circle in Alaska. The balm of Gilead poplar, once known botanically as *P. canadensis* and widely used ornamentally throughout much of the northeastern United States and southern Canada, is now generally regarded to be either a clone from a pistillate tree of the heartleaf balsam poplar (*P. balsamifera* var. *subcordata*) or a hybrid between the balsam poplar and the eastern cottonwood.

The principal poplar of the swamps and river bottoms of the coastal plains and the Mississippi river drainage basin is the swamp cottonwood (*P. heterophylla*). In the Mississippi valley, where they reach their maximum development, these trees are often 80 to 90 ft. tall and 36 to 42 in. in diameter.

The plains cottonwood (*P. sargentii*) is one of the most frequently encountered trees in the otherwise essentially treeless areas of the central United States. Narrowleaf cottonwood (*P. angustifolia*) is a tree of the Rocky mountains and adjacent plains to the east. The ranges of these two species overlap, and at least one natural hybrid between them has become well established. This is known as the lanceleaf cottonwood (*P. × acuminata* [hybrid between *P. angustifolia* × *P. sargentii*]).

Fremont cottonwood (*P. fremonti*) and its variety, Rio Grande cottonwood (*P. fremonti* var. *wislizenii*), are two tree forms not infrequently found along the margins of streams and water holes in the semiarid areas of the southwestern United States. Palmer cottonwood (*P. palmeri*) is a little-known tree of central and the trans-Pecos regions of Texas and northern Mexico.

Of the European forms, the white poplar or abele (*P. alba*) is probably the most important. This is a large tree with rounded and spreading crown composed of several massive, curved branches, which, like the trunk, are clothed with grayish-white bark. Its leaves are ovate to nearly circular, with deeply wavy or more or less lobed margins and heart-shaped bases. The foliage, although dark green above, is clothed below in dense, white pubescence, as are also the young shoots, which, with the bark, give a rather hoary aspect to the tree. Of its several varieties, *P. alba* var. *pyramidalis* (Bolleana poplar), a tree of narrow columnar habit, probably enjoys the greatest ornamental use. A closely related species, the gray poplar (*P. canescens*), with grayish deltoid leaves, is equally well known. Some taxonomists, however, regard this form as a hybrid between the white poplar and the European aspen (*P. tremula*). Both trees have extended ranges through Europe and Asia, and often attain a height of 90 or more feet. Their white, soft, even-grained timber is employed by turners and toy-makers, and is used in quantity in the construction of boxes and crates. Both also enjoy extended ornamental use, although the tendency of white poplar to produce root suckers some distance from the tree restricts its use as an ornamental specimen in some urban areas.

The black poplar (*P. nigra*), a tree of 100 or more feet in height, with smooth, dark green, deltoid leaves and dark, deeply furrowed bark, is a Eurasian species of wide distribution. Its almost universally known variety, the Lombardy poplar (*P. nigra* var. *italica*), is easily identified by its narrow-pyramidal crown composed of many closely appressed and vertically ascending branches. Its origin appears to have been in Iran or some adjacent country. From remote times it has been an inhabitant of Kashmir, Punjab and Iran, where it is still commonly to be observed along roadsides and in formal gardens. It was probably brought to southern Europe from one of these countries, and derives its common name from its abundant use along the rivers of Lombardy. It was introduced into Great Britain in the early 18th century, and somewhat later into the United States. Lombardy poplar's value lies chiefly in its ornamental use, since its rapidly tapering bole, densely clothed in branches for the greater part of its length, is incapable of producing any appreciable volume of utilizable lumber. This tree makes very rapid growth on a variety of sites, and often attains a height of 100 or more feet.

The white, black and Lombardy poplars are widely planted in eastern United States and Canada; the first two of these have become naturalized in many areas.

P. euphratica, believed to be the weeping willow of the Scriptures, is a large tree remarkable for its variability in the shape of its leaves. It is a native of northern Africa and western and central Asia.

Yellow poplar (*Liriodendron tulipifera*), an unrelated species of the magnolia family, is one of the most important hardwoods of eastern United States. See TULIP TREE. (E. S. HR.)

POPLAR BLUFF, a city of southeastern Missouri, U.S., 156 mi. S of St. Louis at the head of navigation on the Black River; the seat of Butler County. Situated in the Ozark perimeter above a broad alluvial plain that forms the rich delta land of one of Missouri's most prosperous farming areas, Poplar Bluff is essentially a farm marketing centre with diversified light industries. It is located at the intersection of two main transcontinental highways and is served by two major railroads.

Founded in 1849 and named for a forest of yellow poplars on the bluffs of the Black River, the city was almost destroyed by guerrilla and troop foragers during the American Civil War. Its subsequent development gained impetus with the construction of the St. Louis, Iron Mountain, and Southern Railway (Missouri Pacific) in 1872. Agricultural growth followed a lumbering boom and reclamation of vast swamp lands between the St. Francis and Black rivers. The county produces cotton, rice, grain, livestock, and lumber. For comparative population figures see table in MISSOURI: Population. (W. E. RO.)

POPLIN, a fine and plain ribbed fabric produced from any class of textile material, comprising a variety of different textures and qualities, and containing fine ribs or cords of uniform size extending across the width of the fabric, from selvedge to selvedge; i.e., in the direction of the weft. The ribbed effect in a poplin fabric is obtained by employing a relatively high number of warp threads of fine counts of yarn and interweaving these on the principle of the plain calico (q.v.) weave, with picks of weft of coarse counts. Hence, during weaving, the finer and weaker warp threads bend or interlace quite freely under and over the coarser and stronger picks of weft which, therefore, lie in a perfectly straight line across the entire width of the fabric and thus develop the fine ribs or cords that characterize all poplin fabrics. Cotton poplin fabrics are used for making blouses, dresses, shirts, jackets, and other garments. Irish poplin, composed of silk warp and worsted weft, is used for ties, dresses, coats, and other clothing.

POPOCATÉPETL (Aztec *popoca* "smoke," *tepetl* "mountain"), a volcano with a large bell-shaped crater approximately 2,600 to 3,000 ft. (800 to 900 m.) in diameter and a snow-covered cone rising to a height of 17,887 ft. (5,452 m.) in México state, central México. Popocatepetl and its twin Ixtacihuatl (q.v.) dominate México City, 45 mi. NW. It is believed that Diego de Ordaz, one of Cortés' lieutenants, was the first European to make the ascent. The last major eruption was in 1802 but there have since been minor ones. There is a road from the town of Amecameca to

L. W. BROWNELL

the foot of the volcano. See also MEXICO: *Physical Geography: Mountains*.

POPOV, ALEKSANDR STEPANOVICH (1859–1906), Russian physicist and electrical engineer, among the earliest scientific investigators of electromagnetic waves (as later used in wireless communication), was born on March 16, 1859, in a mining village in the Ural mountains where his father was a priest. He graduated from St. Petersburg university in 1883 and became an assistant in the physics laboratory, later joining the staff of the torpedo school at Kronstadt, where he subsequently became head of the physics department. Popov became interested in the work of H. R. Hertz (*q.v.*), and began to develop a device for receiving electromagnetic waves (*q.v.*). To detect the oscillations resulting from these waves he made various modifications to the coherer, containing metallic filings, used by Édouard Branly and Sir Oliver Lodge. In particular, he added to his coherer an arrangement for automatically tapping back the filings to a sensitive condition after they had cohered on the reception of oscillations. By this means each received impulse of oscillations caused a bell to ring or a mark to be made on a simple recorder which could operate for 12 hours at a time. This apparatus was used for detecting lightning discharges at a distance and was demonstrated at a meeting of the St. Petersburg Physical society in May 1895. Later, it was set up at the meteorological observatory, the coherer being connected to a lightning conductor and used for the study of atmospheric electrical discharges received at distances up to almost 20 mi. In a second lecture before the society in March 1896, Popov showed the transmission of Hertzian waves between different parts of the university buildings.

In June 1896, Guglielmo Marconi took out the first patent granted for wireless telegraphy based on the use of electric waves. The news of this aroused Popov to fresh activity, and working in conjunction with the Russian navy he effected ship-to-shore communication over distances of about 6 mi. by 1898. This was increased to about 30 mi. by the end of the following year. Unfortunately Popov's work was not sufficiently appreciated and supported by the Russian government, and in 1901 he returned to St. Petersburg as professor at the electrotechnical institute, of which, a few years later, he was elected director. Popov died on Jan. 13, 1906 (new style; Dec. 31, 1905, old style).

(R. L. S.-R.; X.)

POPPY, common name for plants of several genera of the poppy family (Papaveraceae), especially the type genus *Papaver*. This genus comprises annual and perennial erect herbs containing a milky juice, with lobed or cut leaves and generally long-stalked regular showy flowers, which are nodding in the bud stage. The greenish sepals, usually two in number, fall off as the flower opens; the four (very rarely five or six) petals, which are crumpled in the bud stage, also fall readily. Numerous stamens surround the ovary, which is surmounted by a flat or convex rayed disk bearing the stigmas. The ovary develops into a short many-seeded capsule, opening by small valves below the upper edge. The valves respond to an increase in the amount of moisture in the atmosphere by closing the apertures. In dry weather the valves open, and the small seeds escape through the pores when the capsule is shaken by the wind.

Papaver contains about 100 species, mostly natives of central and southern Europe and temperate Asia. Of the five species that occur in Great Britain, *Papaver rhoeas*, the corn or field poppy, is also found in fields in the U.S. Cultivated forms of this, with exquisite shades of colour and without any blotch at the base

of the petals, are known as Shirley poppies. *P. somniferum*, the opium (*q.v.*) poppy, with large white or blue-purple flowers, is native to Greece and the Orient; it is widely cultivated for medical uses, although it is often grown illicitly. The oriental poppy (*P. orientale*) and its many varieties are fine garden plants, having huge bright crimson flowers with black blotches at the base. Many hybrid forms of varying shades of colour have been raised, especially in the U.S. The Iceland poppy (*P. nudicaule*) is one of the showiest species, with gray-green pinnate leaves and flowers varying in colour from pure white through pink and yellow to deep orange-yellow and red shades.

The Welsh poppy (*Meconopsis cambrica*) is a perennial herb with a yellow juice and pale-yellow poppylike flowers. It is found in the southwest and north of England, Wales, Ireland, and western Europe. The prickly poppies belong to the related tropical American genus *Argemone*. *A. grandiflora* is a popular Central American annual with large white or yellow flowers. The horned or sea poppy (*Glaucium flavum*), found on sandy seashores along the Mediterranean and naturalized in the U.S., is characterized by the waxy bloom of its leaves and large golden-yellow short-stalked flowers. The plume poppies (*Macleaya*; often listed misleadingly as *Bocconia*) are ornamental plants with long terminal flower clusters. The snow poppy (*Eomecon chionantha*) is a native Chinese perennial with roundish slightly lobed leaves and pure-white flowers about 2 in. across. The Mexican tulip poppy or golden cup (*Hunnemannia fumariaefolia*), a perennial usually grown as an annual, has very showy yellow flowers. The celandine poppy is *Stylophorum diphyllum*; *Hydrocleis nymphoides* is the water poppy of ponds and aquaria.

The poppy family is well represented in western North America, especially in California, where about 20 native species, together with numerous varieties, are found. The best known is the California poppy (*Eschscholtzia californica*), an annual with brilliant, orange-coloured flowers, widely grown in gardens and extensively naturalized in Australia and India. Other noteworthy Californian species, more or less cultivated, are the tree or bush poppy (*Dendromecon rigida*), a rigid, leafy shrub, 2 to 10 ft. high, with golden-yellow flowers, about 2 in. across; the Matilija poppy (*Romneya coulteri*), a widely branched subshrub, 3 to 8 ft. high, with large white fragrant flowers, 6 in. across; the cream-cups (*Platystemon californicus*), a low, delicate annual, with light-yellow flowers, 1 in. across; and the flaming poppy or wind poppy (*Meconopsis* or *Stylomecon heterophylla*), bearing brick-red flowers 2 in. across.

The common garden poppies (*Papaver* species) grow well when provided with rich well-drained soil in an open sunny location; they require supplementary watering only during dry spells. Some varieties of *P. orientalis* have enormous flowers in nearly all colour shades, but are short-lived and useless as cut flowers. Seed should be sown where plants are to grow, for poppies, especially the annuals, do not transplant well.

(N. Tr.; X.)

POPPYSEED OIL: see OILS, FATS, AND WAXES.

POPULATION. The population of the world rose from about 1,000,000,000 in 1850 to 2,000,000,000 in 1930 and 3,000,000,000 in 1960. It is expected to be in the vicinity of 4,000,000,000 persons in 1980, according to estimates by the staff of the United Nations. It is now increasing at the rate of about 2% per year. This rate, which if continued would double the population before the end of the century, is well above that prevailing in any previous epoch. According to widely accepted estimates, the average rate of increase had risen from less than 0.1% per year in ancient and medieval times to about 0.3% at the beginning of the 18th century and about 0.6% during the middle decades of the 19th century. The acceleration of population increase in the 20th century was the result of a progressive worldwide lowering of mortality.

Differences in population trends among the various regions of the world are strongly affected by differences in fertility. Estimates of population increases and projected trends, by continents, prepared by the United Nations Secretariat, are shown in the accompanying graph. The graph shows that for the world as a whole about 950,000,000 persons were added by the excess of

GIANT SALMON VARIETY OF ORIENTAL POPPY (*PAPAVER ORIENTALE*)

TABLE I.—Percentage Population Increase
(Estimated 1920–60; Projected 1960–2000)

Period	World	Africa	Asia	Europe	Latin America	North America	Oceania	U.S.S.R.
1920–40	22	32	42	16	41	24	28	24
1940–60	29	39	61	11	55	35	39	11
1960–80	39	57	81	13	65	29	40	28
1980–2000	37	62	66	10	59	33	38	26

Source: United Nations, *Provisional Report on World Population Prospects, as Assessed in 1963* (1964). Medium estimates.

births over deaths from 1900 to 1950. The expected increase during the second half of the 20th century is nearly 3,800,000,000, about four times that during the previous 50 years. The term "population explosion" is frequently used to emphasize the extraordinary force of this trend and its possible threat to human welfare. (See also *ECOLOGY; ECONOMIC DEVELOPMENT: Population Growth and Development*.)

No population projections are prophetic. Projected trends for the continents having less-developed countries may be modified by social changes affecting births and deaths, the discovery of new techniques for the control of fertility or in other ways. Trends in the more-developed countries, where mortality at early ages is very low and fertility is already subject in large measure to voluntary control, are peculiarly sensitive to changes in economic conditions and cultural values. The projections merely show the expected effects of processes already in force if these continue without drastic modification. Projections were made on several sets of hypotheses; those shown on the accompanying graph follow from a central assumption of medium, or average, fertility and mortality.

Some idea about variations in population trends among particular countries is given by the information on countries with more than 30,000,000 inhabitants presented in Table II.

KNOWLEDGE ABOUT POPULATION

The scientific study of population, known as demography, began with investigations by John Graunt in the 17th century. Graunt was one of a group of associates in London who were fired with enthusiasm for observations and experiments and received a charter as the Royal Philosophical society, the first scientific academy in the modern world. Graunt, who was a haberdasher by trade, discovered many significant regularities in a series of periodic records of christenings and burials, with reports on the apparent causes of deaths, issued by parish clerks. He published his findings in a pamphlet, *Natural and Political Observations . . . Made upon the Bills of Mortality* of London (1662). This pamphlet, in which Graunt had sketched a hypothetical life table to show the proportions of persons born alive who live to successive ages and the expected years of future life at each age, attracted the attention of scientists in England and on the continent and stimulated other inquiries.

In 1693 Edmund Halley, the astronomer, constructed the first

TABLE II.—Population of Countries with 30,000,000 or More Inhabitants, 1966

empirical life table on the basis of information about deaths by age in Breslau, Ger., which had been forwarded to the London Philosophical society by Leibniz. The measurement and analysis of mortality, which involves study of the frequency of births and the distribution of persons by ages, engaged the attention of scientists in many countries through successive decades. Eventually their investigations led to the systematic exposition of possible interrelations among births, deaths and the age structure of populations. Alfred J. Lotka developed the classic formulation of these relations. Though most of his work was carried out in the United States, his definitive exposition was presented in French:

Censuses.—The major source of basic information on population during the 18th century was the civil register of vital events, established in most European nations to supersede reliance in legal affairs on church records of christenings, marriages and burials. There had already been occasional countings of people in some nations, but these early censuses were sporadic. Usually there was neither a complete tabulation of the returns nor any publication of the results. Quite different opinions were often entertained about the population of a country, even as to whether its population was increasing or decreasing. Scientists investigating these questions experimented with new methods of observation and analysis.

The constitution of the United States prescribed representation in congress on the basis of a periodic census of the population beginning in 1790. Periodic censuses were initiated both in England and in France in 1801. Since that time censuses have gradually spread through the world and supply basic information on most of the world's inhabitants. The greatest gap was apparently closed by the census of China, 1953–54, though its results must be accepted with some reservation. Three-fourths of the popula-

tion of Africa has been described by complete enumerations or national inquiries on the basis of scientific sampling. However, the scope and reliability of censuses differ greatly among nations. (See also VITAL STATISTICS.)

Information on births, deaths and migration is less satisfactory. In the United States, the registration of births and deaths was still very defective in most states at the beginning of the 20th century. Federal birth and death registration areas, initiated at that time, were first extended to include all states in 1933. Before the 1950s reliable vital statistics were lacking for countries containing more than half the world's population; *i.e.*, Asia (except Japan, Formosa, Ceylon and Israel), most of Africa and much of Latin America. By the 1960s many countries in these areas, stimulated by the United Nations World Census programs, had conducted censuses (*see* CENSUS).

Estimates of fertility and mortality can sometimes be obtained by the systematic exploitation of indirect and fragmentary information, but even the critical and skilful use of incomplete information is not a satisfactory substitute for adequate basic data. The measurement of migration, especially within nations, is inherently difficult. Census inquiries are used in many countries to obtain some information on this subject.

MORTALITY

The risk of death varies with age and sex. In general the risk at any given age is less for females than for males, though under some conditions the death rates of women in the childbearing ages may be above those of men at the same ages. The risk of death is high immediately after birth and, with diminishing force, through early childhood; it decreases to a minimum at 10 to 12 years of age. The risk then rises again until at late ages it surpasses that in the first year of life. So the crude death rate of a population (usually expressed as deaths per year per 1,000 persons) is powerfully influenced by its age composition. For comparative purposes, the effect of age composition must always be taken into account in the measurement of mortality. Various standardized death rates have been devised for this purpose, but each is subject to certain technical objections. The expectation of life at birth, as given by a life table, is the most efficient index of the general level of mortality of a population. This is a hypothetical figure. It shows the average years of life to be expected at birth if the risks of death at particular ages in a specified year continue in effect. In Table III the calculated expectations of life at birth are shown for certain countries at particular times.

Mortality Levels.—The range in levels of mortality, shown in Table III, mainly reflects degrees of progress in technology, especially in sanitation and medicine. Prior to the 18th century, the range in levels of mortality was much narrower, except at times of famine, plague or war. In normal times the mean expectations of life at birth were then in the vicinity of 25 to 30 years.

Death rates declined gradually in Europe and North America from the late 17th century onward, at first due mainly to advances in economic conditions and then more rapidly with progress in medicine and sanitation, to the point where further increases in longevity have become largely dependent on the control of organic diseases. Meanwhile, dramatic increases in the chances of survival from birth to late ages have been achieved in countries where the expectation of life at birth was formerly low (*see* Table III). This has been effected mainly by measures to control malaria and epidemic diseases even where, as in Mauritius and Ceylon, there has been little change in nutrition or general levels of living. As a result, the wide differences in mortality among nations have been considerably narrowed during the 20th century. Nevertheless, differences in living conditions still have an important influence on health and longevity between and within nations.

Class Differences.—There are still important differences among social classes within technically advanced nations in levels of mortality, especially in infancy and early childhood. This is indicated by the differences between the figures for whites and nonwhites in the United States (*see* Table III) and by other information concerning families at different economic levels. However, such differences have generally been narrowed in North

America and in Europe, especially since World War II. On the other hand, differentials in mortality between males and females have generally widened—notably in the United States. Various reasons for this phenomenon have been advanced, but none has as yet won a clear consensus among scientists.

Effect on Population Growth.—The lengthening of the span of life is due chiefly to the control of infectious diseases which are especially dangerous in infancy and early childhood. Where the expectation of life at birth is only 30 years, about half of the newborn infants die before age 25 years; but where the expectation is 70 years, over 95% of those born alive pass the 25-year point. Past progress in lowering mortality and that now going on in underdeveloped countries, therefore, exerts a powerful influence on rates of population increase. Future progress in the extension of life in technically advanced countries, being largely dependent on the reduction of deaths at late ages, may be relatively slow.

FERTILITY AND REPRODUCTION

The word fertility is used to denote the actual production of offspring, whereas fecundity refers to biological capacity. The average capacity of a population for reproduction cannot be precisely measured; it varies to an unknown degree under different conditions and perhaps among different stocks. The average capacity of couples under widely prevalent conditions has been estimated at 8.5 to 10 or more births; some couples can have more than 20 births, but others in every society are sterile or become so after the birth of one or several children. In any case, reproduction in human societies is always influenced by customs affecting the frequency of and ages at marriage, divorce and separation, the remarriage of widowed and divorced persons, prohibitions against sexual intercourse under particular conditions, and in many other ways. Various practices, largely magical, both to promote fertility and under certain conditions to prevent conception or induce abortion, are found in most preliterate societies, but they usually have little effect on actual performance. Among technically advanced societies, variations in levels of fertility are determined mainly by attitudes and practices; they have little relation to possible variations in fecundity—though post-World War II increases of birth rates in Europe and North America may have been due in small part to a reduction in the frequency of complete or partial sterility.

Reproduction Ratios.—In most of Asia (except Japan), in Africa and in America from Brazil north through Mexico, each woman who lives through the childbearing years has on the average about six children—though there is, of course, some variation among regions. Between 48% and 49% of all babies are girls. So the average number of daughters born alive per surviving woman (gross reproduction ratio) under these conditions is about three. If the number of children which newborn female infants might eventually bear (if all lived through the childbearing period) is cut in half by premature deaths (between birth and successive adult

ages), there will still be about 150 daughters in each generation per 100 daughters in the previous generation (net reproduction ratio). The population will then tend to increase by 50% during an inter-generation interval, usually somewhere between 25 and 30 years. In past times, this tendency was checked by recurrent disasters. With the same gross reproduction ratio (three) but improvement in sanitation so that only one-third of the potential reproduction is lost by mortality, the net reproduction ratio becomes two. In other words, the population then doubles in each generation. Due to reductions in mortality and the persistence of high fertility, the population of the less-developed countries is generally moving toward, or has already exceeded, this reproductive level. This statement, in the absence of reliable vital statistics, is necessarily based on inferences from census data, investigations in various localities and other indirect evidence; but it is supported by cumulative evidence from many sources.

The general level of fertility in Europe prior to the Industrial Revolution, and perhaps throughout medieval times, was significantly below that now generally prevalent in Asia, Africa and Middle America. The moderation of fertility in preindustrial Europe was not due to the control of fertility within marriage but to social restraints on marriage or procreation at early ages—associated with an emphasis on the nuclear family (husband, wife and children) as contrasted with the larger kinship groups in many societies. These restraints on early marriage were eased among settlers in the open spaces of the new world, so that fertility in colonial America was much higher than in Europe. Different social conditions, also, led to some reduction of fertility in pre-modern Japan, but in this case by resort to abortion and infanticide.

Control of Fertility.—The growth of commerce, new opportunities for individuals to achieve higher levels of living, the withdrawal of children from economic production and provisions for their education stimulated a new interest in the control of fertility within marriage. At the same time, the lowering of mortality increased the probability that most infants would survive to maturity. Then, too, the progress of science and education fostered rationalistic behaviour in the pursuit of personal goals. Incidentally, it seems that men were at least equally and probably more insistent than women on the control of births. So a trend toward the regulation of births within marriage began in France and in the United States near the beginning of the 19th century. Later, but with long lags, it spread through all western and central Europe and then eastward and southward and from cities into rural areas. The control of fertility was at first achieved through an intensification of ancient folk practices, but it was later facilitated by mechanical and chemical means of contraception. It first gained momentum in professional and commercial classes and then spread more slowly through the families of skilled and unskilled workers. This pattern brought wide differences in fertility among the social classes.

As the regulation of fertility has become more nearly universal in Europe, North America, Australia and New Zealand, social class differentials in fertility have been narrowed, though they have not entirely disappeared. The trend toward the regulation of fertility in these regions was apparently approaching completion, in the sense of bringing fertility more or less into conformity with the personal interests of couples, when the world-wide economic depression generated a wave of anxiety to avoid, or at least to postpone, the enlargement of families. Wartime opportunities for

employment and postwar prosperity brought a shift toward earlier marriages, a reduction in the frequency of childless or one-child families and some increase in the number of subsequent births to couples who already had two children—notably in North America, Australia and New Zealand and, to a lesser extent, in Europe. Assuming 1.057 male births per female birth, with 95% of the female infants living to the centre of the childbearing period, of whom 90% marry, an average of 2.16 births per woman living through the childbearing years, or 2.4 births per ever-married woman, will maintain a constant population. Around 1960 fertility was well above this level in North America and Oceania and in some European countries; in some other European countries it was fluctuating in this vicinity. Fertility in the Soviet Union was then similar to that in the United States. The rapid decline of fertility in Japan brought it into line with the low-fertility countries in Europe. In both instances, sharp declines were initially effected by widespread resort to abortion, with a gradual shift toward increased reliance on contraception.

Meanwhile fertility remained at a fairly constant level in most of the underdeveloped countries. Except in periods of rapid change, crude birth rates usually give a fair indication of levels of fertility (in contrast to crude death rates, which are strongly influenced by differences in age composition). Estimated birth rates by world regions are shown in Table IV.

See also BIRTH CONTROL.

AGE AND SEX STRUCTURE

The age and sex composition of a population is determined, apart from the effects of migration, by the frequencies of births in previous years, the sex ratio at birth and the proportions of male and female infants living to successive ages. The age and sex composition of a closed population (not affected by migration) in which the relative frequencies of vital events (births, deaths by age and by sex, and the sex ratio at birth) have been constant for a long time can be calculated mathematically from information on these vital rates. The effects of particular changes in vital rates can also be calculated, but such calculations are more complex.

A population with persistently high fertility has a large proportion of children and a small proportion of aged persons. A population, such as that of France, in which fertility has been low for a long time, has a smaller proportion of children and a larger proportion of aged persons. Changes in fertility have an immediate effect on numbers of children, but 15 years must pass before the change affects the numbers above this age, and 60 years before it affects the numbers of older persons. Therefore, a population that has experienced a recent decline in fertility tends to have relatively small numbers both of children and of aged persons and a large proportion of adults in the middle ages. An upswing in births will again bring an increase in the proportion of children. Thus the rise of fertility in France during the post-World War II period increased the proportion of children in its population while
